The Surgical Aspects of Bronchiectasis, Particularly in Children and Young Adults.—Cumston (*Dublin Journal of Medical Science*, February, 1907) reports the following two cases. Case 1.—Boy, eleven and a half years old, since he contracted whooping cough at eight years of age, had a persistent cough, accompanied by profuse expectoration of a thick greenish sputum. The child was fairly well developed, and healthy in appearance. Some dyspnœa on exercise. The right side of the thorax dragged on respiration, and over the entire lower lobe there was diminished resonance and breath sounds. Numerous coarse moist râles were present. No tubercle bacilli found. On account of the tenacity of the cough in spite of the carefully directed medical treatment, operative interference was decided on. Subperiosteal resection of two inches of the seventh and eight ribs in the posterior axillary line was done. The wound healed by first intention. In three weeks the cough and expectoration had considerably diminished. In five months the general condition of the patient was excellent, and the amount of sputum voided in twenty-four hours would just about fill the bottom of a cup. No distinct dulness could be detected over the right side of the chest, and a weak vesicular murmur could be heard. Case 2.—Female, æt. 7, contracted measles eighteen months ago. This was followed by bronchitis, which has been almost constantly present ever since. Expectoration thick and yellow, but contained no tubercle. On the left posteriorly many coarse râles could be detected. About three inches of the eighth rib was resected subperiosteally. Two months later the severe cough and expectoration had disappeared. The thoracic cavities were symmetrical. The left lung was quite movable, and dulness and râles had disappeared. The author considers that resection of ribs in these kind of cases is a much more satisfactory and safe a procedure than pneumotomy.

S.

Treatment of Conical Cornea. — F. Stauffer (*Ophthalmic Record*, May, 1906) met a case of conical cornea which caused the patient, a young woman, no inconvenience beyond giving the eye an unsightly appearance. The apex of the cone eventually developed an ulcer which threatened the loss of the eye on account of its area and depth. Stauffer decided to remove an elliptical piece of cornea and to use sutures to keep the lips of the wound together. Taking a small curved needle and fine black silk suture, he passed it through the cornea into the anterior chamber, 3 mm. below and 2 mm. to the inner side of the centre of the cornea, bringing it out above at a corresponding point. A similar suture was passed on the outer side. An elliptical piece of the cornea, 3 mm. by 6 mm., was then removed between the sutures in the usual manner and the sutures tied. In twelve days firm union had taken place, and the patient was able to read and sew without the help of glasses.

M.

Retro-Bulbar Neuritis in Influenza.—Prioux (*Soc. Fran. d'Ophthal.*, May, 1906) believes that the systemic symptoms in influenza are due to the absorption of toxins, and that these occasionally affect the optic nerve as other known toxic agents do. He reports a case of influenza in which the right eye developed an acute retro-bulbar neuritis, the left eye showing a distinct œdema of the pupilla. There was a diminution of central perception of red and green, without any visible ophthalmoscopic changes in the right eye. On inunctions and leeches a cure resulted. No history or evidence of syphilis.

NOTICES TO CORRESPONDENTS, &c.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5 ; Half Page, £2 10s. Quarter Page, £1 5s. ; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s. ; 26 at £3 3s. ; 52 insertions at £3, and pro rata for smaller spaces,

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion ; 6d. per line beyond.

SOUTHANTS.—The Budde process of preserving milk consists in the addition of peroxide of hydrogen to clean milk. The mixture is warmed for three hours at a temperature of from 51° C. to 52° C. The peroxide is decomposed and the nascent oxygen acts as a germicide. The milk is immediately bottled, and should keep sweet from eight to ten days. The amount of peroxide added is small, namely 15cc. of a 3 per cent. solution, so that the reduction of the proportion of fat is negligible. The system has been favourably reported on.

AN UNFORTUNATE QUOTATION.

A **NEW YORK** preacher besought his congregation to put the same trust in their pastors as they did in their doctors and lawyers. "If you get a prescription from your doctor, you take the medicine trustfully," and he added :—

"Yours not to reason why,
Yours but to do and die !"

REGISTERED.—It is a delicate point on which we are not infrequently asked for advise. We cannot advise you to use more than moral pressure, but this should be pushed as far as possible. Any respectable firm which values its reputation will do its best to withdraw from circulation anything offensive to you or any man similarly situated. But we do not advise legal proceedings ; they are costly and the issue would be very doubtful.

MISTURA.—There are many anæsthetic mixtures—*e.g.*, Beliroth's mixture (three parts $CHCl_3$, 1 each of alcohol and ether), Vienna mixture (1 part $CHCl_3$ to 3 of ether), the C.E. (2 parts chloroform to 3 of ether), and so on. The A.C.E. mixture was originally proposed by the late Dr. George Harley, and Mr. Martindale showed that the usual proportions, 1 of alcohol, 2 of chloroform, and 3 of ether, produced a mixture in which the evaporation of the constituents was uniform.

D. R. S.—Montana "Spotted Fever" is no relation to the other of that ilk, which is attracting so much attention at present. It is an acute febrile disease found in a certain part of Montana, and is believed to be caused by a similar parasite as Texas fever (*i.e.* a pyrosome). The organism is supposed to be conveyed from squirrels by certain wood-ticks.

L. N.—The dieting of thin people with a view to raising their weight is not so simple as is often supposed, for though fat relieves the intestines from excessive carbohydrate-digestion too much fat leads to bowel disturbance, and if no carbohydrates are taken, to acetonuria. Fat should be judiciously combined with carbohydrates therefore.

H. N. T.—The Royal Commission on Tuberculosis is still sitting and pursuing its investigations. It is impossible to say when its work will be considered to be completed, but we fancy few medical men will be dissatisfied if it goes on for years yet, as it is only by some such agency as this that public money can be got for scientific research. The cost of the Commission so far has been nearly £50,000.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MARCH 6th.

OBSTETRICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8 p.m.: Specimens will be shown by Dr. A. Routh, Dr. Blacker, and Dr. C. H. Roberts. Short Communication :—Mr. A. Doran : After-history of a Case of Fibroid of Broad Ligament associated with an Ovarian Cyst reported in Vol. XLIII. of the Society's Transactions. Inaugural Address :—The President (Dr. H. R. Spencer).

SOCIETY OF ARTS (John Street, Adelphi, W.C.).—8 p.m.: Prof. W. B. Dawkins :—The Discovery of the South-Eastern Coalfield.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. : Mr. P. Paton : Clinique. (Surgical). 5.15 p.m.: Lecture:—Dr. D. Grant : Laryngeal Phthisis.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—2.30 p.m. : Cliniques :—Dermatological (Dr. Meachen), Ophthalmological (Mr. Brooks), Medical Out-patient (Dr. Whipham).

THURSDAY, MARCH 7th.

NEUROLOGICAL SOCIETY OF THE UNITED KINGDOM (11 Chandos Street, Cavendish Square, W.).—8.30 p.m.: Paper:—Dr. H. Howell and Dr. L. Jones : The Effects of Cervical Ribs.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Tichborne Street, Edgware Road, W.).—8.30 p.m. : Discussion on the Diagnosis and Treatment of Fractures in the Neighbourhood of a Joint (opened by Mr. W. Cheyne who will illustrate his remarks with skiagraphs). Prof. H. Marsh, Mr. E. Owen, Mr. P. Gould, Mr. A. Lane, Mr. R. Jones (Liverpool), and Mr. L. Thomas (Cardiff) have promised to take part in the Discussion.

NORTH-EAST LONDON CLINICAL SOCIETY (Tottenham Hospital, N.).—4 p.m.: Clinical Cases.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson : Clinique. (Surgical). 5.15 p.m.: Lecture:—Dr. A. Whitfield : Lichen Planus.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—2.30 p.m. : Gynæcological Operations (Dr. Giles). Cliniques : Medical (Dr. Whiting), Surgical Out-patient (Mr. Carson). 3 p.m.: Clinique :—Medical In-patient (Dr. Chappel).

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6 p.m.: Chesterfield Lecture:—Dr. M. Dockrell: On the Usefulness or Otherwise of the Electrical Methods of Treatment in Skin Diseases.

FRIDAY, MARCH 8th.

WIMBLEDON AND DISTRICT MEDICAL SOCIETY (Worple Hall, Worple Road, Wimbledon).—9 p.m. : Paper :—Dr. W. S. Colman : Pitfalls in Diagnosis.

CLINICAL SOCIETY OF LONDON (20 Hanover Street, W.).—8.30 p.m.: Papers:—Dr. G. A. Sutherland : The Medical Treatment of Congenital Pyloric Stenosis. Dr. A. F. Voelcker : Some Cases of Pyloric Stenosis in Infants. Mr. F. F. Burghard : The Surgical Treatment of Congenital Pyloric Stenosis.

BRITISH LARYNGOLOGICAL RHINOLOGICAL AND OTOLOGICAL ASSOCIATION (11 Chandos Street, Cavendish Square, W.).—4.30 p.m.: General Meeting. Exhibition of Cases and Specimens.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. H. L. Eason : Clinique. (Eye).

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—9.30 a.m.: Clinique. Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques: —Medical Out-patient (Dr. Auld). Ophthalmological (Mr. Brooks). 3 p.m.: Clinique :—Medical In-patients (Dr. Leslie).

Vacancies.

Cornwall County Asylum, Bodmin.—Third Assistant Medical Officer. Salary £140 a year, with furnished rooms, rations, laundry, and attendance. Applications to Medical Superintendent.

Birkenhead Union.—Resident Assistant Medical Officer. Salary £120 per annum, with board, washing, and apartments. Applications to John Carter, Clerk to the Guardians, Poor-Law Offices, Birkenhead.

Aberdeen University.—The McRobert Fellowship for Cancer Research. —Fellow. Salary £200 per annum. Applications to Secretary of the Medical Faculty, the University, Aberdeen.

Birmingham Parish Workhouse Infirmary. — Assistant Resident Surgical Officer. Salary £104 per annum, with furnished apartments, rations, gas, laundry, and attendance. Applications to Charles Fletcher, Clerk to the Guardians, Parish Offices, Edmund Street.

Royal Victoria Eye and Ear Hospital, Dublin.—House Surgeon. Salary £40 per annum, with board and residence. Applications to Edward Parker, Registrar. (See advt.)

Wandsworth Union Infirmary, St. John's Hill, near Clapham Junction.—Male Junior Assistant Medical Officer. Salary £100 a year, board, lodging, and washing. Applications to the Medical Superintendent.

Bristol General Hospital.—Pathologist. Salary £240 per annum. Applications to the Secretary.

Appointments.

GLEGG, R. ASHLEIGH, M.D., Ch.B.Edin., D.P.H., Assistant Medical Officer of Health of the County of Ayr.

GOULD, HAROLD UTTERTON, M.A., M.B., B.C.Cantab, L.R.C.P.Lond., M.R.C.S., District Medical Officer by the Shaftesbury (Dorset) Board of Guardians.

GREEN, T. A., M.D., F.R.C.S.Edin., Surgeon in Charge of the Nose, Throat and Ear Department at the Bristol Royal Hospital for Sick Children and Women.

GROVES, E. J. C., M.B., Ch.B.Edin., House Surgeon at the Brighton, Hove, and Preston Dispensary.

HANLY, THOMAS FRANCIS, L.R.C.P., L.R.C.S., L.M.Edin., Medical Officer of Health for the Shaftesbury (Dorset) Rural District.

HARTIGAN, T. J. P., F.R.C.S.Eng., Dermatogist to the Alexander Hospital, Queen Square, W.C.

JOHNSTONE, G. A., M.B., Ch.B.Aberd., House Surgeon at the Bangor Infirmary.

MACPHAIL, DUGALD H., M.B., Ch.B.Glasg., Extra Physician to the Glasgow Central Dispensary.

MAY, W. NORMAN, M.B., B.S.Lond., Resident Medical Officer at the East London Hospital for Children and Dispensary for Women.

SEWELL, D. LINDLEY, M.B., B.S.Lond., M.R.C.S., L.R.C.P.Lond., Honorary Assistant Surgeon to the Manchester Ear Hospital.

Birth.

CHANCE.—On Feb. 26th, at 90 Merrion Square, Dublin, the wife of Sir Arthur Chance, of a son.

Marriages.

BROWNE—ARTIS.—On Feb. 28, at St. James's, Piccadilly, Harry Fleming Browne, M.B., to Male Mabel Artis.

KEEBLE—GOLDSBROUGH.—On Feb, 23rd, at Camberwell Green Congregational Church, John Bright Keeble, of the British Central Africa Protectorate, to Edith, second daughter of Giles F. Goldsbrough, M.D., of Wimpole Street and Herne Hill, London.

MCSHEEHY—BUCKLEY.—On Feb. 27th, at the Servite Church, London, Joseph Thomas, eldest son of Surgeon-Major McSheehy, M.D., J.P. (late of the 5th Dragoon Guards), of Donoman, Wimbledon, to Katherine Josephine (Kitty), daughter of the late Fleet-Surgeon Buckley, R.N., and of Mrs. Buckley, 48 Cathcart Road, London.

Deaths.

TODD.—On Feb. 27th, at 126 Alexandra Road, Wimbledon, Nannie B. Todd, widow of the late Mark Stanley Todd, M.R.C.S., etc.

MACFADYEN.—On March 1st, at 14 Daleham Gardens, Hampstead, N.W., Allan Macfadyen, M.D., aged 46.

HARLEY STREET.—To MEDICAL MEN.—One of the best Houses in the Centre of the Medical Profession, with stabling, for Sale, having a lease of 33 years unexpired, at a very low ground rent.—For detailed particulars apply to W. Burnell Tubbs, Surveyor, 68 and 69 Shoe Lane, E.C., and 37 Barbican, E.C. Phone. 3,755 Central.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIV. WEDNESDAY, MARCH 13, 1907. No. 11

NOTES AND COMMENTS.

Unregistered Dentists and Anæsthetics.

THE subtle distinction between unregistered and unqualified practitioners, both in medicine and dentistry, is quite lost on the public generally; the most they can be expected to understand is whether a man is or is not a "doctor" or a "dentist." The safeguard of registration as designed by the law is a clumsy business at best, and in the case of dentistry is of little value, for a practitioner has only to put a case of artificial teeth outside his door, or on the platform of the nearest railway station; with the inscription, "Teeth Painlessly Extracted," for him to be regarded as a dental surgeon. Indeed, to the poor the case of teeth is as pathognomonic of a dentist as the red lamp is of the doctor. Now, although the unqualified practice of dentistry is not, on the whole, attended with the same serious risks as that of medicine, it is a great danger to the public in respect of the administration of anæsthetics. It is generally agreed by medical men and dental surgeons that for the proper performance of a dental operation under an anæsthetic a qualified anæsthetist should be present, so that the dentist may give his undivided attention to his own work. In the case of unregistered dental practitioners, however, medical men are guilty of "covering" if they assist, and these people, consequently; are obliged to give their own anæsthetics—an art of course in which they have had no proper instruction.

Their Limitations and Responsibilities.

AT Nottingham last week a case in point occurred which shows what dangers the public must constantly be running through this practice. A woman went to an unregistered dental practitioner in that town and by him was given an anæsthetic while some extractions were done. Two of the teeth, however, were broken, and after suffering much pain for a week the woman went back to him and was given ethyl chloride, in order that the stumps might be taken out. According to a companion who was present, she "took it very calm," but the calmness soon passed into that form from which there is no waking. At the inquest, the dental operator said that he had given ethyl chloride 2,500 to 3,000 times in the last six years, an average of about eight times a day. A medical practitioner who was called in said he found the woman dead and that the dress was very tight round the waist. There was no obstruction of the respiratory passages and no disease of the heart. No wonder that the jury suggested in a rider to their verdict that "before ethyl chloride was administered in future patients should be examined by a doctor"; it would have been still more to the point if they had said that no unregistered person should be allowed to give an anæsthetic. Ethyl chloride is not a drug to be lightly handled, and the omission to take such a simple precaution as loosening the clothes round the waist shows how little sense of responsibility is attached to its administration.

Health Visitors.

ANOTHER class of persons whose limitations should be clearly defined are women health visitors. Now that the community is waking up to the terrible slur on its humanity which is cast by the high infant mortality of large towns, these visitors are becoming more common, and very properly so. Well-instructed health visitors who have tact and judgment can undoubtedly exercise a most beneficent influence in the homes of ignorant or careless parents, by impressing on them their duties to infants and by giving general advice as to cleanliness, clothing, and feeding in normal cases where no medical man is in attendance or likely to be called in. But it is obvious that the line between the duties of health visitors and those of medical practitioner is in many cases a narrow one, and if these ladies wish, as doubtless they all desire in principle, to be of real value in their districts, they must work in close co-operation with the people's own medical attendants. Otherwise unlimited sources of friction will arise, and their ministrations may be more productive of harm than good. We all know the temptation when dres't in a little brief authority to expand that authority, or, at any rate, to push it to its full limit.

And Their Functions.

AN instructive instance of the necessity for care in this direction is supplied by an inquest held early this month at Kensington on a child who is said to have been puny from birth. A midwife had attended the mother in her confinement, and a health-visitor from the Borough Council had seen the child ten days after birth. According to the mother's evidence, the child's breathing caused her some disturbance, and the health visitor prescribed some camphorated oil to be rubbed on the chest. The mother apparently persisted in this treatment for a long time, but the child growing worse and worse, she sent for a doctor. It was then exceedingly ill, and died a few hours afterwards from what the post-mortem revealed to be pneumonia. The jury brought in a verdict to that effect, adding the very proper rider: " In view of possible dangers arising from unqualified medical advice, we are of opinion that the borough officials should instruct their nurses to adhere strictly to nursing duties and to abstain from giving medical advice." There has been a good deal of local feeling expressed on the subject, but the warning is a timely one, and made in the best of good taste by impartial jurymen with the facts before them. Health visitors came into existence at the instance of the medical profession, and there is every reason why the most cordial relations should exist between both parties; but that can only be if each recognises its proper functions.

Fluid Fees.

There is no question in general practice so delicate and surrounded with pitfalls as that of the proper fee to charge patients. Although there are general rules for guidance, these are very fluid, and have to be interpreted in the widest fashion, so much do circumstances influence different cases. It is inevitable, therefore, that while most patients think they are charged fairly, and many, indeed, lightly by their medical attendants, there should be a residuum which considers particular bills too high. It is difficult for people to understand why the same amount of attention that costs them half-a-guinea should be given to others who only pay five shillings, but there is no alternative in practice but to charge not according to time or trouble, but according to people's means. At the recent Shropshire Assizes, Dr. J. A. Shackel was obliged to bring an action to recover £145 9s. from a baronet, Sir William Rose-Boughton, for attendance on his father, the defendant only admitting liability for £88 1s. 6d. The question at issue was whether a guinea a visit was too high a charge for attendance on a gentleman of the baronet's position, especially as Dr. Shackel had charged lower fees to other members of the family. Happily, judgment was eventually given in the medical man's favour, and it may be remarked that it is quite fair that a county gentleman of title and estates, whose life has publicity attached to it, should pay at a higher rate than a more obscure individual, and a guinea a visit, especially when there is a considerable journey to make, is a decidedly moderate charge under the circumstances.

Rank and "Gowd."

Eminent position in society has always been regarded as a good reason for assessing the value of medical services at a higher figure. The responsibility entailed on a medical man attending a person whose illness attracts wide interest is far greater than in the case of a lowly and uninfluential person, and as medical charges have a good deal of the " moral and intellectual damage " element about them, they are justly raised in the case of well-known and well-to-do people. Many of the subjects of the charges, however, wish to obtain all the privileges of their station without its corresponding obligations. We were once consulted in the case of one of the wealthiest peers in the country who objected to pay twenty guineas for a corresponding number of visits by a leading practitioner in a fashionable town. In such cases it is necessary to represent that " the rank is but the guinea-stamp," though the man does not always like producing the " gowd for a' that."

LEADING ARTICLE.

A NATIONAL ANTHROPOMETRIC SURVEY.

The scientific study of mankind in his collective relationships is obviously a matter of first importance as regards the future of the race. It has been to a great extent effaced, however, by the overwhelming amount of attention that has been demanded by the individual. Modern schools of statesmanship have, nevertheless, begun to recognise that the strength of a nation must ultimately depend on the general standard of virility attained by her citizens. Indeed, that is the great underlying principle of the gospel of public health, which has sought in many ways to protect the community as far as may be from the physical evils due to a bad environment. As a first step in any comprehensive study of the effects of modern life upon the individual it is clearly necessary to secure a fairly full knowledge of existing facts. As an illustration of the profound racial changes that can be brought about by environment, the interesting statements of Mr. J. Gray, an authority on the subject, may be quoted. He states that a recent survey carried out in Scotland showed that in Glasgow hair and eye colours had changed so radically that the population of the town could no longer be considered to belong to the same race as the normal denizens of Scotland. This change he attributed to the industrial environment of the city in question, which had eliminated certain types of the population and had more or less modified its general composition. Anthropometry proved conclusively that under modern industrial conditions people with fair hair and with blue and light-coloured eyes—the Saxon type—died out and disappeared. It is interesting to note that similar investigations in the crowded London slums of Southwark and the Borough led to the same conclusions. The result of these observations is the interesting general proposition that the fair race of the industrial slum area dies out at a far greater rate than the darker race. The explanation probably lies in the fact that fair people are less resistant to diseases that are common to industrial life. If that were not the case, we should expect to find that the fair-haired races were less resistant under all conditions of environment. It was shown, however, by anthropometric investigations in Edinburgh, which consists for the most part of residential districts, that the balance of the fair-haired and the dark-haired population is about equally preserved. If this doctrine be accepted, it is clearly advisable for all fair-haired and blue-eyed persons to go and live in the country, if they wish to attain the span of life allotted to mankind by the psalmist. The matter may, of course, be looked at from another point of view, namely, that the standard of environment in town and industrial life should be raised so that fair-haired folk would thrive and survive there no less than they would in rural quarters and non-industrial occupations. In any case, progress in scientific human culture demands the possession of full knowledge on which to base our proceedings. With that end in view, on the 5th instant, a deputation waited on the Prime Minister to urge the Government to establish a national anthropometric survey both of adults and of children, on the lines recommended by the Inter-departmental Committee on Physical Deterioration, in July, 1904. The Deputation included such well-known scientific authorities as Professor D. J. Cunningham Sir Lauder Brunton, the Rev. J. Gow, Sir W. S. Church, Dr. Arthur Keith, Dr. Arthur Thompson Dr. Tuke, and Mr. J. Gray. They pointed out that the machinery for such a periodical survey was ready, but a grant from the Government of between £4,000 and £5,000 was wanted to put it into efficient action. The reply of Sir Henry Campbell-Bannerman was encouraging, and pledged the Government so far as could be reasonably done by a cautious and responsible Prime Minister. The practical experience of the politician naturally suggested to him certain difficulties that might arise in the endeavour to enforce systems of examination upon rich and poor alike, as well as upon their children. In other words, the first element of success is to secure the approva of the public. He promised that the views of the deputation should receive careful consideration, and that the Government would be glad to givel them the modest sum asked for if they found the project generally approved. Here the matter rests for the present. It may be added that the object aimed at by anthropologists was defined by one of the deputation as the securing of a continuous record of exact measurements of the physical and mental characters of the population, and to take particular notice of the environment in which the subjects of the measurements lived.

CURRENT TOPICS.

Lead Poisoning by Drinking Water.

A RECENT report of Dr. Helwes on a large number of cases of lead poisoning at Diepholz suggests some interesting considerations. Thirty-one persons were affected ; they were all of the middle class, and the amount of lead in the drinking water varied from 0.2 to 3.98 mg. per litre. The familiar fact of the immunity of all save one single member of a household towards the poison was again illustrated in several instances, but no fresh light was thrown upon this somewhat curious anomaly. A less familiar and in some ways a far more serious matter is the fact that in by far the larger number of instances the appearance of lead poisoning was noticed only after the pipes had been in use for many years, and when examination of the metal work showed little or no trace of attack. Given the factor of individual susceptibility, there can be no permanent security while lead is used in the conveyance or storage of moorland water used for drinking purposes. It is certainly somewhat alarming to learn that lead pipes may be used for many years without deleterious effects and then suddenly give rise to plumbism. This information prepares us for the further conclusion of Dr. Helwes that more persons suffer from lead poisoning than is generally believed. The hint is well worthy of being borne in mind by all engaged in medical practice.

Episcopal Surgery.

AT a recent meeting of the Hostel of St. Luke, held in the Church House, Westminster, the Bishop of Selkirk gave some interesting details of his early experiences in remote regions where skilled medical assistance is not to be had. His experience in the Arctic regions, hundreds of miles away from doctors and nurses, made him appreciate such an institution for the clergy as the hostel. People had come to him to have fingers taken off and teeth pulled out. One lady came 1,500 miles to have a tooth taken out, a fact that emphasised in a remarkable way the horrors of toothache. He practised on his wife, and she practised on him, a method of acquiring clinical experience that is somewhat too limited for the ordinary medical student. Once when he lived among the Esquimaux in a snow house he became suddenly ill with pleurisy; so he mixed mustard and snow with splendid effect and made himself well again. His predecessor as bishop amputated a man's leg with a common saw and a butcher's knife. Much of the practice of surgery is clearly within the grasp of a man of resolution and manual dexterity, but the same observation applies much less to the more difficult methods of the physician.

The Prevention of Disorder in the Royal University of Ireland.

A WHITE Paper has been issued containing the text of a Royal Warrant to amend the Statutes of the Royal University of Ireland, and to confer upon the Senate the necessary disciplinary powers which recent events at the conferring of degrees showed to be badly required. The Warrant contains six provisions, the first of which enables the Senate to decline to award a pass to any candidate who shall be adjudged to have violated any of the regulations in connection with any examination. The Senate may also refuse to allow such a candidate to present himself for re-examination for such a period as they may think fit, and is given the power to impose a fine not exceeding five pounds. The Senate is further given powers to remove from the University Register any undergraduate who shall be adjudged by the Senate or by the Standing Committee to have been guilty of serious misconduct at any of the functions of the University, or to decline to allow such undergraduate to enter for any further examination in the University for such length of time as the Senate think fit, or to inflict such fine, not exceeding ten pounds, as they shall think fit. They are also granted similar powers with respect to graduates. It is to be hoped that these powers will be sufficient to enable the Senate to preserve order at its functions in future, and to prevent such University ceremonies from being converted into a semi-political bear-garden, to the discredit of University education in Ireland. *En passant*, we may note, however, that the issue of this Warrant seems to be superfluous if, as we are told, the Government intend to abolish the Royal University after Easter.

The Military Chest.

The grotesque side of army dress and carriage has furnished powder and shot to the caricaturists time out of mind. There seems to be hardly any absurdity too great for the military tailor bent on making the most of his "gilded popinjay" as a well-known statesman once somewhat unkindly called the British officer. Speaking seriously, it is somewhat hard to realise how brave and modest men, as most soldiers are in private life, can consent without a murmur to doff the sober dress of the modern gentleman and don the hues of the peacock, together with accoutrements that would look ridiculous in a circus entertainment. In point of fact progress in the army is a plant of slow growth, and it is wont to hug many a worm-eaten tradition as regards dress and drill and other details of its daily life. But the spirit of reform appears to have settled upon the War Office. We wonder if medical science will be called upon to advise as to the scientific treatment of the soldier. If so, one of the first things to go by the board will most likely be the erect bearing and puffed out military chest. The athletic layman does not stand as if he had a ramrod down his back, nor does he puff out his chest in the fashion of a pouter pigeon. It is more than likely that the habitual assumption of such a carriage during many hours of arduous work and exercise lead to serious damage both to lungs and to heart. Dr. Gordon Hogg, Coroner for West Middlesex, recently called attention to this most "pernicious practice" of puffing out the chest adopted in the British army. It seems quite clear that the excessive incidence of aneurism upon soldiers is directly due to the drillmaster's mistaken sense of propriety of carriage. Perhaps Mr. Haldane, who appears to be a kind of Hercules in such things, will seek medical counsel and advice upon this knotty problem.

Antivivisection and Falsehood.

There is nothing more painful to scientific men who are fond both of animals and of justice than the methods used by the rival antivivisection bodies to hoodwink the public on the question of experiments on animals. "Good wine needs no bush," and if the antivivisection cause were a good one it would gain respect and adherents by presenting unvarnished facts—indeed, one might go further and say that we can conceive of the public interest being served by honest opponents of experiments on animals, criticising fairly things which they deemed to be wrong, for just criticism temperately delivered is one of the most useful factors in the regulation of society—our whole system of Government depends on it. The antivivisectionists, however, positively revel in wild and wicked exaggeration, and do not scruple even to tell the grossest falsehoods. The honest man has no place in any of the antivivisection organisations of our time. One of the latest ebullitions from these tainted sources is a letter, entitled "What Vivisection Costs the Public," from Mr. Sidney Trist, Secretary of the London Antivivisection Society, which appeared in the *Star* of March 4th, and the *Western Daily Mercury* of March 2nd, and perhaps in other journals, for the letter appears to be of the kind that is sent simultaneously to leading papers, in which the statement is made that "every year the British Medical Association receives from the Treasury several thousands of pounds for 'scientific grants,' mainly vivisection. The taxpayer pays." The secretary of the British Medical Association wrote the *Star* the following day, giving this statement the lie direct. "This statement," he wrote, "is absolutely false and untrue." So far we have seen no apology, even the lamest, from Mr. Sidney Trist.

Deaths under Anæsthetics.

A correspondent has drawn our attention to a somewhat striking contrast between the number of deaths from anæsthetics in England and that in Ireland, as revealed by the statistics of the respective Registrars-General. It appears that in the year 1904 there were in England and Wales 161 deaths registered as due to anæsthetics, and in the following year 157. In Ireland there were only three deaths in each year. Moreover, of the 161 deaths in 1904 in England and Wales, 92, and of the 157 in 1905, 81 were under chloroform anæsthesia. All the six deaths in Ireland were under chloroform. Again, of the total of 318 deaths in England and Wales, in the case of 48 in 1904 and of 57 in 1905, the nature of the anæsthetic is unrecorded. As chloroform is probably the most common anæsthetic agent in use in England, it is fair to assume that it was the agent in the great majority of these cases. As the population of England and Wales is about ten times that of Ireland, and the number of deaths under anæsthetics some fifty times as many, there is a difference to be explained. Assuming that the figures are equally trustworthy in the two countries, and that the incidence of operation on the population is approximately the same, then only one explanation of the disparity is possible. In Ireland ether is the anæsthetic of choice, chloroorm being rarely used except where there are definite indications for it. In England the use of the latter is still very common.

Railway Carriages and Dirt

EVIDENCE of an important character in regard to public health was given a week or two ago before the Railway Commission in Ireland by representatives of the Commercial Travellers' Association. These gentlemen, among other matters with which we have no direct concern, drew the attention of the Commission to the filthy condition in which railway carriages are kept on many of the lines in Ireland. Spitting is practised everywhere, and not only the floors, but the doors and windows of the carriages are contaminated. The carriages are seldom, if ever, thoroughly cleansed. Heating and lighting are insufficient, and ventilation is entirely at the will of the passengers. We have often drawn attention to the part played by railway carriages in the spread of disease, and we think the Commercial Travellers' Association has done a service in pointing out the risks to which its members and the travelling public generally are exposed by the neglect of common cleanliness on the part of the railway managers. We cannot but think, however, that some body claiming to speak with authority on matters of public health should have brought forward evidence on the subject, and not have left it to a lay association.

A Chinese Medical College.

THERE is hardly any more marvellous chapter in the history of science than the way in which Japan brought herself into line with modern Western medical knowledge. The other great nation of the Far East, China, still hugs an ancient system of medicine founded on barbaric superstition and ignorance. In various directions, however, China is beginning to follow, *longo intervallo*, in the wake of her Japanese neighbours. The Union Medical College of Pekin appears to be at last making a real impression upon the national mind. Lord Overtoun, who presided at a recent meeting in Glasgow of the promoters of the College, gave various interesting details concerning the Institution. A year's work has been completed and the work is being run by a combination of five missionary societies. Perhaps the most significant fact connected with the movement is its recognition by the Dowager-Empress, who not only gives her sanction to the work, but couples it with a considerable donation. It is perhaps somewhat to be regretted that the precepts of modern medical science cannot be instilled into the mind of a great nation without the accompaniment of religious teaching; both are undoubtedly excellent things in their way but there is no obvious correlation between them.

Another Martyr to Science.

ANOTHER medical man has lost his life at the post of duty. Dr. Macfadyen, one of our most distinguished bacteriologists, by an accident, inoculated himself with the poison of Malta fever, in the preparation of which he was engaged. Even the most cautious and skilful workers are exposed to a certain irreducible margin of risk when handling specific pathogenic cultures. In the particular disease mentioned the fever usually runs a chronic non-fatal course, but in the case of Professor Macfadyen its unfavourable issue was no doubt influenced by the lowered resistance of a frame taxed for some time past with anxiety and overwork. In his death we recognise another added to the long list of medical martyrs to science.

PERSONAL.

ON March 9th Her Majesty the Queen and the Empress Marie paid a private visit to the London Hospital, of which the Queen is president. Attended by members of their suites, their Majesties drove down to the hospital from Buckingham Palace, arriving at midday, and spent several hours in inspecting wards and patients.

LAST week, Her Majesty the Queen, attended by the Marchioness of Lansdowne and the Hon. Charlotte Knollys, paid a surprise visit to the offices of the Queen's Victoria Jubilee Institute of Nurses in Victoria Street, London.

THE Imperial Association of Physicians in Vienna resolved, on March 8th, to hold the usual annual ceremonial sitting this year in honour of Lord Lister. The inaugural speech, dwelling upon his merits and achievements as a member of the medical profession, will be given by University Professor Dr. Fraenkel.

LIEUT.-COL. L. A. IRVING, R.A.M.C., it is stated, has resigned his appointment as recruiting medical officer in the London District. Capt. P. J. Bodington, R.A.M.C., is to be appointed to the Royal Horse Guards. Major T. B. Beach, from Chatham, has been appointed to the Royal Arsenal, Woolwich, for duty.

DR. F. G. HOPKINS, Senior Medical Officer of Southern Nigeria, has been promoted Deputy Principal Medical Officer, and Dr. E. H. Read, Medical Officer, becomes Senior Medical Officer.

LIEUT.-COLONEL W. BABTIE, C.M.G., V.C., has been selected for the appointment of Inspector of Medical Services under the new Army plans.

THE DUKE of DEVONSHIRE has been elected Chancellor of the Victoria University, Manchester.

THE Gold Medal founded by the late Sir Gilbert Blane, Bart., to be given biennially, has been awarded by the Medical Director-General of the Navy and Presidents of the Royal College of Physicians, and the Royal College of Surgeons, to Staff-Surgeon James W. W. Stanton, for his Journal of H.M.S. *Suffolk*, 1905, and to Surgeon Bernard Ley, for his Journal of H.M.S. *Algerine*, 1904.

THE DUKE of ARGYLL has consented to preside at the festival dinner of the Royal Waterloo Hospital, to be held at the Savoy Hotel on May 14th.

MR. LEONARD BIDWELL, Dr. Rolleston, and Mr. WARING are to continue on March 19th the debate opened last night at the Chelsea Clinical Society on "Gall-Stones, their Diagnosis and Indications for Operation.

DR. BEATTIE, Lecturer on Bacteriology at Edinburgh University, has been elected Professor of Pathology at Sheffield.

A CLINICAL LECTURE

ON

SOME PNEUMOCOCCAL AFFECTIONS REQUIRING SURGICAL TREATMENT.

By E. W. SCOTT CARMICHAEL, M.B., F.R.C.S.E.,

Assistant Surgeon, Royal Hospital for Sick Children, Edinburgh.

GENTLEMEN,—The subject which I wish to bring before you to-day is one which has been illustrated by several cases recently admitted to hospital. It serves to show how increasingly widespread infections by Frænkel's pneumococcus have become since more thorough bacteriological investigation has isolated the specific organism in acute infective conditions. This organism has been shown to affect serous membranes throughout the body, not only in association with a lung affection, but also independently as far as clinical evidence and post mortem examination can determine.

Pneumococcal infection of the meninges of the brain, peritoneum, synovial membranes of joints and tendons are more frequently recognised than formerly.

The following case, gentlemen, illustrates well a pneumococcal affection occurring independently of any pulmonary condition :—

A female infant, æt. 6 weeks, was brought up to the out-patient department of the hospital on December 24th, 1906, with the history that it seemed to suffer pain when it was moved, especially when the mother tried to straighten its legs when washing it. Swelling of the left wrist was also noticed three days before.

On examination the child was fairly well nourished, there was general swelling of the wrist joint and an abscess over the lower end of the radius on its dorsal aspect. The child lay with both thighs and knees flexed. Attempts to extend the hip joints showed considerable fixation of the right. The hollow behind the trochanter on the right side was filled up with an elastic swelling, giving a sense of deep fluctuation. The temperature was 101° F.

The history, age of the infant, and clinical examination justified the diagnosis of an acute arthritis of the right hip and left wrist, and the child was admitted to Mr. Kay Smith Ward.

On the following day the hip joint was explored, and drained by a posterior incision. No primary bony focus could be found either in the neck or upper epiphysis of the femur, and we therefore had to deal with a primary acute synovial infection of the joint.

Drainage of the wrist joint was also carried out. I think, if one considers the state of development of the structures entering into the formation of the wrist joint in a child of this age, we may consider that we had here also to deal with a primary synovial infection.

The centres of ossification of the lower ends of radius and ulna, and of the first row of carpal bones have not yet appeared at this age, nor has the epiphysis of the head of the femur. The ossific centres for the acetabulum are present at this age, but are so small as to preclude the probability of a primary bone affection.

We have therefore to deal here with a primary synovial affection of both joints. What, then, is the probable cause ? What organisms are most likely to affect the synovial membrane by means of the blood stream with acute symptoms as presented by this case, and suppuration ?

We have either to deal here with a pneumococcal or streptococcal infection. Clinically, the child does not present the severe toxic symptoms of a streptococcal infection, and I was inclined to think that we had a simple pneumococcal infection of both joints. Bacteriological examination of the fluid from both joints gave a pure culture of Frænkel's pneumococcus.

This, therefore, gentlemen, is a fairly typical case of a generalised pneumococcal infection with local manifestations in the hip and wrist, or, in other words, the child suffers from a mild form of pneumococcal septicæmia. This case also illustrates the fact that we may have a general pneumococcal infection without any local manifestation in the lung, as far as can be ascertained clinically.

I wish, therefore, now to consider pneumococcal arthritis in general.

AGE AND SEX.

It may occur at any age, but is probably much more common in children than any other period of life. When it occurs in children it is most common during the first year, at the time of dentition.

Of eight cases which have been treated in this hospital during the last three years, five were under the age of one year, two were æt. 13 months and 14 months respectively, and one was æt. 7.

Thus a large proportion of cases of acute suppurative arthritis in infants are due to the pneumococcus.

It seems to affect male children more frequently than females. All the eight cases above referred to were males, although the case presented to you to-day is that of a female, æt. 6 weeks.

GENERAL CONDITION.

This child, though obviously ill, did not present that extreme degree of toxæmia which might be expected when two large joints are the seat of acute sepsis, and in many cases this is somewhat typical of the condition.

The general disturbance does not correspond to the degree of the joint affection. This child eats and sleeps fairly well, and does not present the restless, poisoned appearance of one suffering from a strepto or staphylococcal infection. The temperature varies from that of a typical affection of the lung in the more severe forms to one in which it is somewhat irregular, but does not extend higher than 101° F. When one joint is affected the temperature chart may resemble that of an acute lobar pneumonia, with a marked crisis, but in many cases, especially when there is more than one joint affected, the fever shows no such regularity.

In only one of these nine cases was there any affection of the lung or pleura associated with the involvement of the joints. In adults a joint infection is much more frequently secondary to or coincident with a lobar pneumonia, but in children the arthritis of one or more joints appears to be more frequently the primary local manifestation.

The blood reaction is as a rule well marked, as shown by a high leucocytosis, a distinct glycogen reaction, while in severe cases pneumococci may be cultivated from the blood.

CONDITION OF JOINTS.

The disease is essentially one which affects the larger joints and in about 50 per cent. of cases affects more than one joint.

In those cases treated in this hospital, the order of frequency of the various joints has been the hip, knee, shoulder and wrist, and in all probability the knee is the joint most frequently affected.

The joints present all the signs of an acute inflammation as shown by tenderness, swelling, and pain. There is one sign, however, which is occasionally striking, though not always reliable, and that is the absence of periarticular œdema. In the case of the child shown to you to-day, however, the infection has spread beyond the joint into the surrounding cellular tissue and formed an abscess outside the joint, and this is the stage at which the condition is generally met with by the surgeon, especially in the case of the hip joint, in which it is difficult to detect a distension of the joint until an abscess has formed under the gluteus medius, and maximus and filled up the natural hollow between the great trochanter and the dorsum ilii.

It is important to remember the character of the pus as seen in pneumococcal joints. It is met with in two forms, either it is thick, and of a greenish yellow colour, or like somewhat thin cloudy serum. In both instances it is odourless, and the one variety may occur in one joint and the other in another joint in the same individual.

It seems probable that the serous fluid occurs in an early stage of the disease, although some authorities believe that this thin turbid pus is evidence of a more virulent infection. In one case, however, of a baby, æt. 7 months, with acute pneumococcal arthritis of the hip, the joint contained somewhat turbid, almost gelatinous, looking fluid having a slightly greenish tinge and with no odour, the joint subsequently recovered with almost no limitation of movement.

The recuperative power of joints in infants and young children after septic infection is much greater than that of the adult, so that even after drainage for some considerable period the power of mobility of a joint is not seriously interfered with. This is not infrequently the case in pneumococcal infection of a joint in which the prognosis is rather more favourable as regards mobility than in other septic conditions.

It is not necessary to drain the joint for a prolonged period, and in two cases drainage tubes were removed after the third and fourth day. The purulent effusion into the joint does not apparently persist so long as in other septic conditions.

Prognosis as to life becomes more unfavourable the greater the number of joints affected. In three cases in which more than one joint was affected, two ended fatally, while in six cases where only one joint was involved, one died, the cause of death being meningitis.

As compared with most septic conditions in joints, the prognosis as to the future function of the joint itself is much more favourable.

Before passing on to the next series of cases, gentlemen, I would have you consider the following points, which a review of these cases teaches:—

(1) That a large proportion of acute infections of joints, more especially in infants under one year, are due to the pneumococcus of Frænkel.

(2) That such infection is often evidence of a general septicæmia.

(3) That in the majority of cases there is no evidence of a primary infection in the lungs as far as can be ascertained clinically.

(4) That the degree of toxæmia is relatively less, and the prognosis therefore more favourable, than in other acute infections.

I wish now to consider more briefly several cases which we have recently had under observation, illustrative of another serous membrane infection, namely pneumococcal peritonitis.

Like the joint affection, it is more common in childhood than in later life. It tends, however, to affect older children, and rarely infants. Thus of 11 cases treated in the hospital, one only affected a baby of 13 months, the remaining cases being, with one exception, in children over six years of age.

It is generally believed to occur more frequently in the female than in the male, but of the 11 cases above referred to 7 occurred in males and 4 in females. It is probable that in the adult the female is more often attacked than the male, the source of infection being in these cases by means of the Fallopian tube, although this channel cannot be overlooked even in the case of the young child. Whether this is so or not can only be determined by more careful pathological examination, as it has been shown (Armand and Bowen) that where the peritonitis has been secondary to a lung infection, the female is affected in 67 per cent. of cases.

In the cases above referred to three were secondary peritonitis, in that there was also a pulmonary affection. Of these two were females.

One cannot help thinking that if pneumococcal peritonitis is more common in the female, its greater frequency cannot be entirely laid at the door of a tubal infection.

Clinically we may consider two varieties of pneumococcal peritonitis, the generalised and the localised or encysted. The former is the more common variety. Of the 11 cases referred to two were localised.

A localised pneumococcal abscess is generally situated below the umbilicus, is often lateral and tends to occur more frequently on the left than the right side. If untreated it may burst in any direction, but the point of election is at the umbilicus. Localised abscess of the peritoneum is more frequently a secondary affection than the generalised form, for when the latter occurs it is usually one of many lesions in a pneumococcal septicæmia.

In the localised form, the general condition of the patient is often good, but if left untreated wasting becomes a marked sign, until the abscess bursts into the bladder, vagina or rectum, or at the umbilicus. The child when seen at this stage often presents the appearance of one suffering from a tuberculous condition; especially is this so when an umbilical fistula is present.

In generalised peritonitis the onset is acute, and the symptoms severe, terminating in death in many cases in forty-eight hours. There is evidence of gastro-enteritis, as shown by vomiting and diarrhœa, and marked general toxæmia in cases resembling the galvinating form of appendicitis. All degrees of severity are met with down to that in which the patient presents chiefly gastro-intestinal symptoms without marked toxæmia. There is tenderness of the abdomen without any degree of distension, and were it not for the somewhat marked abdominal tenderness, the presence of diffuse peritonitis might be unsuspected.

Diarrhœa is a symptom which is more constantly present than in any other form of general peritonitis.

How does infection take place; is it by the blood stream, or by direct intestinal infection? The fact that vomiting and diarrhœa are such prominent symptoms in most cases, would seem to point to a spread from an intestinal infection, but it is possible that where generalised peritonitis is present with other lesions the infection has occurred by means of the blood stream.

The diagnosis of the condition is not always easy. When general peritonitis is present, especially in a child, the vermiform appendix is in the majority of cases the cause. If on palpation there is no swelling in the right iliac fossa, pneumococcal peritonitis or a pelvic appendicitis becoming generalised offer the most probable explanation. A rectal examination is often unsatisfactory owing to the extreme tenderness of the pelvic peritoneum in both cases, but under an anæsthetic a localised swelling would suggest the appendix as the more probable cause.

When a localised abscess is present the case often does not come to the surgeon till the patient has been treated for some weeks.

The history will as a rule serve to distinguish it from a tuberculous condition, although the appearance of the patient may be similar in both conditions. Where a fistula is present palpation will reveal masses if the condition is tuberculous.

What, then, would justify a diagnosis of pneumococcal peritonitis, apart from the clinical history? One of the most distinctive features of the condition is the character of the pus as revealed at operation.

On opening the abdomen, a clear somewhat fibrinous fluid, sometimes even jelly-like in consistence and mixed with a somewhat yellowish green pus, escapes. It is always, when a pure infection, odourless, which serves frequently to distinguish it from pus of appendix origin.

In localised abscesses the pus is not so characteristic, but it is probable that many of these encysted abscesses result from a less severe generalised infection, which has cured except for the local collection. The want of odour and fibrinous character of the pus is even in these cases a distinctive character of a pneumococcal infection.

The prognosis in general peritonitis is grave, while that of the localised form is relatively good. It is better in cases where the peritonitis is a secondary lesion.

The successful treatment depends, gentlemen, on an early diagnosis. It is not, however, easy to diagnose this condition in its early stage, but fever, abdominal tenderness and diarrhœa are strong indications for operative interference. Multiple drainage without washing out the abdominal cavity gives the best results.

I have tried, gentlemen, to bring before you the salient features of these two conditions, which illustrate the greater frequency of what up till recently were unrecognised affections as far as their bacteriology was concerned.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by T. K. Monro, M.A., M.D., F.F.P.S.G., Physician to the Glasgow Royal Infirmary and Professor of Medicine in St. Mungo's College, on "Diabetes."*

ORIGINAL PAPERS.

THERAPEUTIC NOTES.

BY PROF. WILLIAM CARTER, M.D., B.SC., LL.B., UNIV. LOND., F.R.C.P.LOND.,

Professor of Therapeutics, Liverpool University; Physician to the Liverpool Royal Southern Hospital.

IN the art of medicine as well in that of govenment the application of abstract principles is often less successful in effecting cure or relief than the employment of remedies that are sometimes condescendingly spoken of as merely empirical.

In the few notes which I propose to write, it is rather to the application of some practical remedies that I shall ask attention than to any of the theories of modern therapeutics, useful and suggestive though some of these undoubtedly may be.

"Do you consider trypsin of any value in the treatment of cancer?" is a question that has more than once been put to me. By way of reply I will transcribe verbatim the notes kindly forwarded to me by Dr. McAfee of the case of a lady, who, when I saw her in consultation with him, seemed to be in a hopeless condition—merely premising that I was led to suggest the use of trypsin owing to a report which had been given to me, on the occasion of one of his visits to England, by my friend Dr. Albert Chalmers of Ceylon, of its beneficial effects in two cases of uterine cancer that seemed from his description closely to resemble the one now to be related.

Dr. McAfee's Report.—"Patient, æt. 51, unmarried, had panhysterectomy performed for adeno-carcinoma of the uterus. The left ovary was found to be seriously involved, considerable infiltration had taken place into the tissues around, and from soon after the time of operation—in July, 1900—up till the beginning of 1905, it was evident that the disease was making progress in the pelvic region; a considerable mass could be felt in the left groin, and a large ulcer formed in the posterior wall of the rectum. This soon necessitated colotomy, which was performed in March, 1905. The patient was much relieved by this operation up till August of that year, when several alarming syncopal attacks occurred, and there was much exhaustion; pain in the pelvis was intense, and frequent discharges from the rectum took place with symptoms of septicæmia.

"The patient became steadily worse; increasing weakness, with symptoms of absorption and constant distress from the activity of the rectum, notwithstanding the injection of local sedatives, pointed to a rapidly fatal termination.

"On February 19th the use of trypsin was commenced. Two drachms of the liq. trypsin co. (Allen and Hanbury) made up to one ounce with water were injected daily, and one drachm three times a day administered by the mouth.

"There was an immediate improvement in both the local and general condition. At first the rectal injection was only retained from ten to twenty minutes, but the relief was remarkable after a few days. The discharges from the bowel which had necessitated the use of the slipper ten or twelve times a day, were reduced to twice. The sense of urgent pressure ceased, and the general increase of comfort was most gratifying. Sleep returned, the digestion improved, and wasting was checked. The abdomen became less tender, and a marked diminution of the resistance in the left groin became evident; in a month the patient was able to get out of bed to a chair, and several times during the summer she has been able to take drives of considerable length.

"The period of the retention of the trypsin has been increased to two or three hours, when a considerable discharge has returned by the opening in the side. This is far in excess of the bulk of the injection and is often of a gelatinous character, occasionally very offensive.

"The patient is now more free from pain and discomfort, sleeps more soundly, and is better nourished than at any time since the colotomy was performed. An injection of 20 minims of liq. Battley twenty minutes before that of trypsin has allowed the latter to be retained longer; and in the month of June the trypsin caused some nausea, and a slight erythematous rash appeared. This led to the omission of its administration by mouth for one day of the week, and has probably conduced to toleration of the drug."

Such is Dr. McAfee's report, and, in order to learn whether the improvement continued, I telephoned to him for information as these notes were being prepared for the Press. The reply was in the affirmative, and that the patient shortly before had had an hour's carriage drive, not only without discomfort, but with pleasure and apparent benefit. When it is remembered that the act of sitting up in her bedroom even, much less of going downstairs, and less still of driving out of doors, would not have been thought possible ten months previously, and, moreover, that a microscopic examination had determined beyond question that the growth was an adeno-carcinoma, this case seems to point to the possible power that may be possessed by trypsin of differentiating between one form of cancer and another.

In a recent volume of the Liverpool reports I published the case of a lady, æt. 36, from whom it had been decided to remove by operation a very large tumour of the left side of the upper jaw, involving all the adjacent tissues and protruding the left eyeball. All the medical gentlemen who had been consulted, and they were numerous, considered the growth malignant; and it was probably in despair of any supposed rational hope of relief by other means, that operation had been suggested. Yet, in the course of two or three months, under the influence of X-rays, all trace of the growth had disappeared. But if I had been asked why I had recommended the application of X-rays in one of these cases and treatment by trypsin in the other, I could have given no other reply than that both had been proved to be beneficial in some—though it must be admitted only in some—apparently similar cases. What we want to know is when, and on what grounds, we can rationally anticipate success. To elucidate this very obscure subject there should be a close co-operation between the clinician on the one side and the physiologist (including, of course, the microscopist) on the other. I am reminded in this connection of some wise words written by Pawlow. "My belief," said he, "extends to this: that it is only by an active interchange of opinion between the physiologist and the physician that the common goal of physiological science and medical art will be most quickly and securely reached."

It may perhaps be added that the matter discharged after the injection of trypsin (a portion of which I had the opportunity of examining), besides the physical characters mentioned by Dr. McAfee, had a sp. gr. of 1033, was alkaline in reaction, very albuminous, and contained trypsin; but as 20 fl. oz. were sometimes discharged while only 1 fl. oz. of the trypsin solution was injected, it obviously contained very much more. Whether the additional fluid discharged was the result of any solvent action produced by the drug upon the cellular or other elements of the growth, must be matter of conjecture. What is not matter of conjecture, however, is the very great improvement in the patient's condition which followed, and, as we think, was caused by, the treatment.

Not long since I drew attention, in a clinical lecture published in the *Lancet*, to the prompt relief which followed the administration by the mouth of 10-minim doses of oil of turpentine in a case of rapidly recurring hæmorrhagic effusion into the left pleural cavity, where other means, including the intrapleural injection of adrenalin solution, had signally failed. A more recent, and in some respects a more remarkable case, which seems to teach the same lesson, deserves perhaps to be placed on record. The patient, a gentleman, æt. 41, whom I had seen on June 20th, 1906, at St. Anne's-on-the-Sea, in consultation with Dr. O'Connor, suffering from hepatic disease of a serious character, was the subject, a few weeks later, of an enormous effusion into the left pleural cavity. The amount of fluid was greater than I remember ever to have seen, reaching, as Dr. O'Connor informed me on the following day, between nine and ten pints. The flow continued so long that I was compelled to leave before the measurement could be made. Re-accumulation took place rapidly, and when I saw him three weeks later the left pleural cavity was again full. I was agreed, therefore, to replace the iodide and acetate of potassium, which had been given internally, and the 10 per cent. oleate of mercury in oleic acid, which had been applied to the chest-wall, with 10-m. doses of oleum terebinthinæ, and the application of moderate-sized blisters. The report on August 24th was: "There is friction all over the left side." And during September and October there was still no reaccumulation. Of course, it may be said that credit should be given to the blisters. Truly, and the wise plan will be to use both agents. Still, severe counter-irritation by means of a strong solution of oleate of mercury had not been followed by relief—which was, however, at once experienced on the administration of the oleum terebinthinæ.

I have more than once drawn attention in these columns to the practical advantage of that complex—that curious complex, as many think it—of remedies known as Warburg's tincture in the treatment of cases of malarial fever that resist quinine, as well as other remedies, such as arsenic, methylene blue, etc., when administered in any of the ordinary ways. An illustrative example has just occurred in the tropical ward of the Royal Southern Hospital, and its relation may encourage those who are not as yet practically acquainted with the effects of the drug to employ it in obstinate and chronic cases, where strength is becoming exhausted by the fever. The main symptoms were daily recurring fever—the temperature on one occasion reaching 106.8°—profuse sweating, frequent rigors, vomiting, and steady emaciation. The patient, a highly intelligent male, æt. 31, was greatly depressed by the persistence of his illness, which, with a few small fluctuations, had continued from August 23rd, 1906, to September 23rd, 1906, when, on Warburg's tincture, of which an isolated dose had previously been occasionally administered, being steadily given twice daily, the temperature speedily fell to normal and remained so for sixteen days, when he was transferred to a surgical word for the treatment of a fistula, and there was no further rise during the remainder of his stay in hospital.

Among the methods of rapidly curing severe cases of chorea, none perhaps are so useful as the administration of large doses of strychnine or arsenic, the former of which drugs has, unfortunately, as I venture to think, fallen out of use lately. Having had ample practical experience of both of these methods, I propose to say a few words concerning them. As the late Dr. Murray, of Newcastle, pointed out in his very useful little book, entitled "Rough Notes on Remedies," doses of from 15 to 20 minims of liquor arsenicalis can often be borne three times a day for a week by even quite a young child, at the end of which time the patient is not unfrequently cured. But sometimes the drug cannot be borne.

An even better remedy is found in strychnine in those very severe cases where life seems to be in immediate danger owing to the severity and persistence of the symptoms. I am aware that the employment of the drug was urged in such cases by Trousseau, but I am equally aware that it is falling into disuetude notwithstanding the advocacy of that prince of clinicians, as well also as that of such men as Dr. Hammond, of New York, and the late Dr. Murchison. The kind of case where its best results are shown will now be related. A. R., æt. 16, had been ill for five weeks before admission under my care into the Liverpool Royal Southern Hospital. He had been unable to speak at all for three weeks, and could speak but very indistinctly for ten days previously. His pupils were widely dilated. He lay in an apparently idiotic condition, noticing nothing and scarcely able to swallow; liquid placed in his mouth having to trickle back to the fauces before feeble effort at deglutition was made. Both hands dropped at the wrists. The right leg seemed to twitch more than the left. The movements were quite as strong during sleep as when he was awake. The boy was extremely emaciated, and a strong and very peculiar odour was given off from the skin. The temperature oscillated between 100° F. and 100.5° F.; the pulse was very variable, ranging from 80 to 112. Urine and motions were passed into the bed. As soon as a little of the former could be collected its sp. gr. was found to be 1046, but it contained neither sugar nor albumen. Chlorides were present in abundance. When, on the day but one after admission, he was asked to hold out his hand, he appeared to make a feeble effort, showing apparently that he understood what was said, but that he was unable to carry out his intention. I think this was as bad a case as I have ever seen. Nothing but constant care on the part of the ward sister and nurses prevented the skin of the back and elbows from breaking down owing to the incessant chafing to which it was subject. As it was, it became very hot and angry-looking. In order if possible to quiet the extremely violent movements, several enemata, of which each contained one drachm of bromide of potassium and a little tincture of Indian hemp, were administered; but, from the first, strychnine was given, commencing with $^1/_{30}$ gr., and quickly increasing the dose till, on April 8th, he was taking $^1/_{16}$ gr.; on the 10th, $^1/_{13}$ gr.; on the 18th, $^1/_{10}$ gr. and on the 28th, nearly $./_{6}$ gr. During the whole time—after the first few days—the improvement was steady. The power of speech slowly returned. He could answer questions on April 18th, and speech seemed quite restored by May 1st. The twitchings ceased before the 13th of April, but he was miserably weak and emaciated, and was on this account retained in hospital for some weeks longer. With the subsidence of the movements his temperature became, and for a long time remained, subnormal; often continuing throughout the entire day as low as 95.6°, the pulse at the same time ranging between 48 and 60. The sp. gr. of the urine fell to 1014. He continued to take large doses — gr. three times a day—until his discharge on June 30th. He wrote his name in a very fair hand, free from tremor, on June 27th. Until the choreic movements ceased he did not appear to notice the bitter taste of the medicine; so soon, however, as they had ceased he required something to take after each dose.

My belief was that the strychnine was the means of saving the boy's life.

The amount of strychnine that can be advantageously taken in some other conditions, such, for example, as post-diphtheritic paralysis or the paralysis of beri-beri, is very great. I have now under treatment in the tropical ward of the Royal Southern Hospital, a Chinaman suffering from beri-beri, whose dose three times a day is at present ¼ gr. of the hydrochloride. From being absolutely paralysed he is now able to walk, and that without the aid of a stick, when not being observed—though he always wants more or less support from his stick when we are watching him. But, on the other hand, some people are so susceptible that much less than half that dose will cause spasm of voluntary muscles. Such was the case lately with a married lady, where a dose of 5 m. of the liquor strychninæ hydrochloridi was prescribed, to be cautiously increased at intervals of two days up to 10 m.; beyond which there was to be no increase, but a reversion slowly to the original dose. The third dose of 10 m. was followed by closure of the jaws, inability to open them, difficulty of breathing and a sensation of suffocation. Such was the description of her condition sent to me by the doctor who saw her, and all this when she was taking hardly more than one-third of the dose given apparently with great advantage to the man with beri-beri.

SOME POINTS IN THE TREATMENT OF ENLARGED PROSTATE.

By L. G. GUNN, M.D.,

Assistant Surgeon to the Adelaide Hospital, Dublin.

It is hardly possible to read the current British and American medical journals without finding every week one or more papers on the treatment of enlarged prostate; most of these seem to have been written with this purpose—to demonstrate that the author's plan of operating on the gland is the best method, and that he and he only was the inventor of the operation.

It seems to be taken for granted that some form of operation is the only possible treatment. The non-operative treatment is seldom mentioned, yet I venture to think that there are more patients at the present time treated by non-operative measures for enlarged prostates, and with a large measure of success, than there are patients who are treated by operation.

To-night I wish to deal with the broad general lines, rather than with the details of treatment, to avoid any discussion as to which operative procedure is the most useful, to remain silent on operative technique, for these points are to the surgeons present already familiar, and to those who are not engaged in operative work their recital can only be wearisome.

During the past two years I have had some opportunity of seeing enlargement of the prostate treated at three different centres of learning—at London, at Paris, and at Berlin—on diverse lines by men who had specialised at genito-urinary work. I propose now to give you an outline of these three methods and then, very briefly tell you the plan I try to carry out myself in the treatment of such cases.

At Prof. Hartmann's clinic the diagnosis was made from the symptoms, the urine examined for pus and albumin, a rectal examination, sometimes followed by the passage of a soft catheter to find out the amount of residual urine. The treatment is carried out on general hygienic lines; the patient is handed a paper bearing the following instructions: wine, beer, liqueurs, coffee, tea, all spicey foods, tomatoes, asparagus, must be avoided. Take a teaspoonful of bicarbonate of soda and dissolve this in a litre of filtered water; take a wineglass of this at each meal. Take short brisk walks; do not remain more than seven hours in bed; let the bed be a hard one. Make each morning a dry friction with a rough cloth on which has been sprinkled a few drops of spirit or eau de cologne over the entire surface of the body. Do not try to pass water oftener than is natural.

As long as the patient can pass water nothing further is done unless the urine contains pus, and the patient shows signs of septic absorption. Under these circumstances a soft catheter is passed daily and the bladder washed out with 1-5,000 oxycyanide of Hg. Should the patient be unable to pass water, he is taught to clean and pass a gum elastic catheter, and told to wash out the bladder each time the instrument is passed.

The male patients attending this clinique averaged about 150 per diem. A fair proportion of these cases suffered from enlarged prostate, yet during four weeks there I saw no case advised to have his prostate removed.

In Berlin, at Frank's Clinique, the number of patients was not so large, but the methods of examination were far more thorough. The symptoms were taken in the usual way, the urine submitted to a careful micro and macro-scopic examination; if bacteria were present, they were, as a rule, planted out. The rectal examination was followed by a cystoscopic examination of the interior of the bladder, the amount of residual urine being measured at the same time.

The treatment in cases where the urine was aseptic consisted in passing occasionally, about once a month, a full-sized metal bougie and leaving this distending the prostatic urethra for five minutes. Purgatives were freely given, and great stress was laid on this, but no attempt was made to stop beer or alcohol.

If the obstructive symptoms were severe prostatectomy was advised in all cases with aseptic urine.

In cases with septic urines a partial operation, such as Bottini's, was performed.

If the sepsis was very severe the bladder was washed out by catheter for a few days and then perineal drainage was established.

Of the treatment adopted in London I can speak with less certainty, as the time there at my disposal was very limited. The diagnosis was made by taking the symptoms and a rectal examination; microscopic examination of the urine did not seem to be the rule. The residual urine was tested by passing a soft catheter.

The treatment recommended in every case seemed to be prostatectomy.

In looking at these three methods of treatment I felt that a less severe treatment than that adopted at London might have sufficed in some of the cases, that the Berlin method of treating the more septic cases did not seem satisfactory, while some of the Paris cases would undoubtedly have been benefited by an operation.

I try to apply the following principles in the treatment of enlarged prostate:—

Let the examination of the patient be as complete as possible. Examine the urine macroscopically and microscopically, the rectum, the urethra, and the interior of the bladder, by this finding out the extent the gland is enlarged up into the bladder, the appearance of the prostate, whether suggestive of malignancy or not, the presence of calculi, the condition of the bladder walls, if sacculated, the discharge of pus from either ureter, for on these findings the treatment of the case must largely depend.

In mild cases, where the bladder wall is healthy, where the urine is aseptic, and the patient able to pass water, though not empty his bladder, I stop all alcohol, keep the bowels free, promote the healthy action of the skin, warn the patient against exposing himself to wet or cold, pass once a month, if necessary, a full-sized metal bougie. In such cases the indications for operation would be the pain being severe, the presence of calculi, the possibility of the gland being malignant. In cases where a mild chronic cystitis is present I adopt the same treatment with the addition of internal urinary antiseptics. The indications here for operation are sacculation of the bladder or signs of infection spreading to the kidneys.

In septic cases which require catheterization, wash the bladder for a week before doing a prostatectomy; the contra-indications to operation are—extreme age, great weakness, or a double pyalitis. In acutely septic cases with much fever I drain the bladder for a few days before doing a radical operation and give stimulants freely during this time.

It is possible you may think from my remarks that I am not in favour of prostatectomy. This is not the case. The operation is often admirable in its result and in many cases the only way in which a patient can be relieved from his distress, but at the same time I do think that many medical men hold mistaken ideas about this operation of prostatectomy. It is looked upon as an operation easy to perform, uniformly successful in its results and having almost no mortality. Quite lately a patient informed me that his doctor told him that the operation consisted in making a small opening into the bladder and picking the gland off the floor, the operation only lasting a few minutes. This gentleman had not seen, as I have, a urinary surgical specialist struggle for forty minutes before he succeeded in "picking the gland off the floor of the bladder." Again, after this operation a stricture may form, or if the compressor urethra is injured, incontinence may occur, leaving the patient in a very miserable condition, a supra-pubic or perineal fistula, as the case may be, sometimes persists for a long time, and causes much discomfort. Lastly, as to the risks of the operation, I would put the mortality at about 8 to 10 per cent., in spite of lengthy statistics showing almost no mortality. When I think of the age at which this operation is usually performed, the amount of sepsis often present, and the extent to which the patient's kidneys are sometimes diseased, it seems impossible to me that prostatectomy should not have a considerable mortality, and this mortality must be borne in mind in recommending a patient to submit to the operation. On the other hand, I do not think that the risks of a prostatectomy can ever be so great as those incurred by the constant use of a catheter.

PSYCHORHYTHM AND RECURRENT PSYCHOSES. (a)

By THEO. B. HYSLOP, M.D., M.R.C.P.,

Senior Physician, Bethlem Royal Hospital; Lecturer on Insanity, St. Mary's Hospital.

PART II.

(*Conclusion*).

I now pass to the consideration of some recurring psychoses which are coincidental to or alternating with metabolic processes, and for convenience I propose to discuss briefly, seriatim—

(1) Alternations;
(2) Recurring insanities of metabolic origin;
(3) Recurring insanities due to bacterial toxæmia.

Alternating conditions are always of great interest to alienists. It has long been known that nervous and mental disorders may be relieved by acute bodily disease. Acute mania, melancholia and even delusional insanities have been temporarily or even permanently relieved by some intercurrent inflammatory condition. We have in Bethlem now a general paralytic of nearly thirty years' standing whose disease was arrested by an extensive inflammation and abscess of a limb. Savage has described alternations as occurring between hysteria, epilepsy, headache, asthma, chronic bronchitis, rheumatic fever, gout, eczema, diabetes and insanity. These alternations may recur several or many times before health is re-established. The presence of a definite bodily affection is in itself sufficient guide for the treatment and most of these cases yield sooner or later to systematic treatment.

(2) Insanities of metabolic origin are, of course, due to auto-intoxication by reason of defective metabolism. They may be classified as follows:—

(*a*) Auto-intoxications from the suppression or disturbance of the functions of an organ—

Thyroid—Myxœdema, cachexia strumipriva.
Pancreas—Diabetes.
Liver—Acute yellow atrophy.
Supra renal capsules—Addison's disease.

(*b*) Auto-intoxications which occur from anomalies in general metabolism without any definite localisation—

Gout—Oxaluria.

(*c*) Auto-intoxications caused by retention of the physiological products of metabolism in the different organs—

Carbonic acid in defective respiration.
Uræmia.
Eclampsia gravidarum.

(*d*) Auto-intoxications due to over-production of physiological and pathological products of the organism—

Hydrothionæmia, ammoniœmia, acetonuria.
Diaceturia, cystinuria, also diabetic coma.
Coma carcinomatosum, etc.
Basedow's disease.

In all these metabolic forms of insanity when there is a tendency to periodicity or recurrence at more or less definite intervals, there is usually also an hereditary taint. The development and decline of the periods are comparatively rapid. The commonest forms are—

(1) *Recurrent or periodical melancholia.*
(2) *Recurrent or periodical mania.*
(3) *Circular insanity* (*folie circulaire*).

Space will not permit me to describe these types in detail. I prefer rather to refer to some of the latest clinico-pathological investigations.

Typical periodical melancholia usually begins mildly although somewhat suddenly. Recovery is followed by a lengthy period of comparatively good health until the second attack, which is more severe, and followed by a shorter period of health. The second attack may be similar to the first, and each subsequent periodical attack exhibits but few deviations. There is one form of periodical melancholia occasionally met in the male, and coinciding with a diminished output of uric acid. It sometimes recurs as frequently as at monthly intervals, and each attack may last a week or ten days. I have seen hallucinations of hearing with desperate suicidal impulses recurring time after time in one such case now under my care.

Periodical mania is more frequent than periodical melancholia, particularly in females. It is sometimes synchronous with menstruation. Sometimes these mental attacks may tend with advancing years to merge into each other, and there is diminution of mental debility without true dementia. Some observers believe that dementia is a very rare termination.

Circular insanity consists essentially of an alternation of maniacal and melancholic conditions, which either follow one another immediately or are separated by an interval. A typical case of mild form runs as follows:—Without being regarded as insane the individual passes his entire life in a periodical alternation of moderate excitement and depression. When excited, there is merely a slight change of character, and at times unusual activity. His condition may pass unnoticed by persons who do not know him well. This state passes slowly or suddenly into one of depression with reticence, general malaise and loss of appetite. Not infrequently it runs in families and it is generally to be found in individuals with hereditary taint. The female sex is more prone to it than the male. In the more severe cases the depression may pass into actual stupor, and the excitement into acute mania, with impulsive violence. Hallucinations seldom occur except in the severest cases when the change coincides with the period of menstruation. Hitherto the prognosis has been regarded as rather unfavourable, but in some cases the climacteric starts a decided improvement. In view of the recent researches by Bruce and others there is hope that more enlightened treatment may lead to better results than hitherto.

Macpherson divides the causes of toxæmia into:—

(*a*) Auto-intoxication as the result of—

(1) Physiological instability.
(2) Defective metabolism.
(3) Defective gland secretion.
(4) Auto-intoxication from the alimentary tract.
(5) Auto-intoxication from the liver and kidneys.

(*a*) **Read before the Harveian Society, February 14th, 1907.**

(*b*) Intoxication from micro-organisms introduced into the system.

(*c*) Voluntary intoxication by alcohol and drugs.

Bruce believes it is highly probable that they all depend on some degree of hepatic insufficiency, the liver failing to arrest or destroy toxines produced by any of these causes; and, secondly, renal insufficiency through the kidneys failing to excrete the toxines by the urine. Certain it is that perversions of the functions of the kidneys are very frequent in insanity and although much has already been done in this direction, there is still open a very wide field for research.

Whilst recognising that maltrutrition and deficient excretion of the waste products may cause almost any of the types of insanity other than those already referred to as being due to deprivation, the greatest interest centres around the recurrent melancholias and manias and the condition of folie circulaire. Failure in the secretion of the thyroid gland gives rise to the well-known condition of myxœdematus insanity. Excessive or altered secretion may be followed by maniacal outbreaks or other mental symptoms. The chief interest in these conditions rests in their tendency to periodicity or recurrence, and one attack, for obvious reasons, is unable to confer immunity against further attacks. In some of the very acute infective conditions, such as acute delirious mania, acute delirious melancholia, however, it is not infrequent to have no recurrence of the disease, and this in itself is in some instances suggestive not only of bacterial toxæmia, but it also suggests that immunity may be conferred in this way.

I have seen two cases of very acute delirious mania which were apparently of bacterial origin, and after careful investigation it was ascertained that in both instances the infection was derived from contact with diseased sheep. The details of these investigations are not yet completed, so I am unable to lay them before you. It must suffice for the present to say that we are merely on the threshold of lines of research which will ultimately bring the work of the bacteriologist and the alienist into very close contact.

I will now refer briefly to some of the results of the investigations undertaken by Bruce, who has carried further the work of Macphail, Krypsiakiewicz, Kroumbmiller and others.

Starting on the hypothesis that a leucocytosis between 6,000 and 10,000 per cm. of blood is what one might expect to find in health, he examined blood taken from the lobe of the ear as nearly as possible at the same hour every day just before the midday meal. The numerical counts were made with Thoma Zeiss' hæmocytometer according to the method of Coles, and never less than 40 fields were counted at each examination.

In acute mania, if examined early, there was in every case a leucocytosis of from 18 000 to 20 000 per cm., and sometimes even higher. The percentage of polymorphonuclear cells was never below 70 per cent. This lasted only a few days, then the leucocytosis fell sometimes as low as 10 000 per cm., but never lower. More generally the leucocytosis was 14,000 or 15,000 per cm. Along with this change the percentage of the polymorphonuclear cells fell, but there was a corresponding rise in lymphocytes. Any subsequent increase in excitement was attended by a further increase in the leucocytosis with a mild degree of eosinophilia of 3 to 5 per cent. With convalescence the polymorphonuclear cells diminished to between 60 and 70 per cent., whereas in many cases the leucocytosis persisted for weeks or months after complete recovery. This leucocytosis Bruce believes to be a protective leucocytosis, favouring the supposition that acute continuous mania is an acute infective disease with subsequent establishment of immunity.

In those cases which do not recover the leucocytosis tends to fall and the percentage of polymorphonuclear leucocytes may fall below 40 or even 30.

There is much to be said in favour of his theory that cases of recurrent mania might be described as conditions of continuous toxæmia with recurrent attacks of mental excitement and confusion.

Similarly the variations in the amount of leucocytosis and in the percentage of polymorphonuclear leucocytes occurring in association with the different stages of folie circulaire are highly suggestive and may lead to a more comprehensive grasp of the true nature of the morbid processes. Treatment undertaken to modify the amount of leucocytosis is up to the present uncertain and of little value.

I have avoided any discussion upon the question of the presence of bacterial agglutinines in the serum of cases of insanity. The facts at hand are insufficient to justify any definite statement.

I have avoided detailed descriptions of the features of folie circulaire, and I have not entered into any discussion as to whether it may be regarded as a distinct disease as did Falret and Baillarger, who first described it. Kraepalin describes this great class of diseases under manic-depressive insanity, and folie circulaire is now included under periodic or recurrent insanities. The practical outcome of the observations of late years may be summed up very briefly as follows:—Most of the recurrent psychoses which formerly were regarded as inexplicable are now within a measurable distance of elucidation by means of the clinico-pathological evidences of defective metabolism.

CLINICAL RECORDS.

A CASE OF RENAL CALCULUS SIMULATING APPENDICITIS.

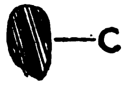
By S. J. ROSS, M.D.Vict.,

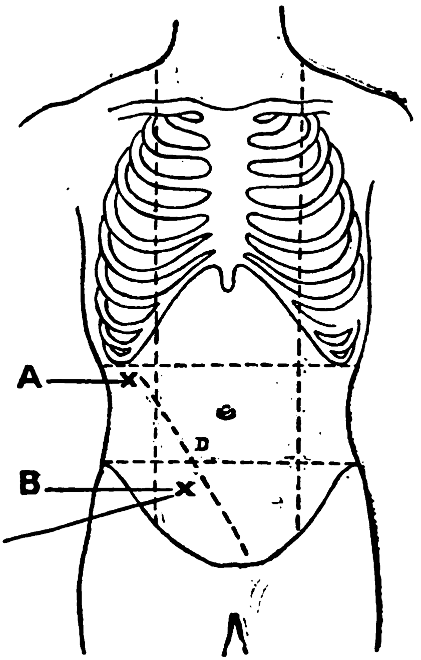
Surgeon Out-Patients, Bedford County Hospital.

I WAS called on January 15th of this year to see a youth, æt. 20, who was said to be suffering from appendicitis. He had had three similar attacks during the past twelve months.

C—Calculus passed per urethram.

Actual size.





A.—Region of pain on Jan. 6th.

D—direction

B—Region of pain on Feb. 2nd.

The present attack began on January 14th and was ushered in by shivering, vomiting and fever.

When I saw him on January 15th I found that his temperature was 101 degrees. He complained of acute pain over his right kidney. Percussion over the back of the right kidney increased the pain. There was marked retraction of the right testicle. The pain radiated downwards towards the symphysis pulvis. His urine on the previous day was very high coloured, but now was white and turbid with a white sediment.

Specific gravity 1019 alkaline phosphatic, a trace of albumin. I placed him on milk diet, told him to drink plenty of barley water, and gave him a diuretic mixture. I also told him to watch his water carefully for any sign of a stone.

On January 16th his temperature was normal and he was free from pain. On January 27th his urine was quite clear, acid and having had no recurrence of pain he determined to get up, and on January 31st returned to work. On February 2nd I was called to see him on account of intense pain situated in the region of the right iliac fossa, 1½ inches from the middle line and radiating towards the right pulvic spine. I thought that the calculus was in the right ureter and had been stopped at the narrow part of the conduit where it crosses the pelvic brim. The pain, relieved by occasional doses of morphia, finally disappeared on February 12th. On February 17th the patient passed a phosphatic stone, the exact size and shape of which are indicated in the diagram.

The previous attacks of appendicitis so called were doubtless attacks of renal colix.

There appears to be no doubt that the stone was found in the renal pelvis, and the time occupied from the first appearance of symptoms to the final liberation of the stone per urethram was 34 days.

Finally, we may note that not every pain which is referred to the iliac fossa has its origin in the appendix.

OPERATING THEATRES.

KING'S COLLEGE HOSPITAL.

Operation for Chronic Middle Ear Disease, Suppuration, Necrosis of Posterior Labyrinth, Facial Paralysis, Large Parotid Swelling and Pus tracking down to the Soft Palate and Tonsil.—Mr. **Arthur Cheatle** operated on a man, æt. 22, who came to the hospital on December 3rd, 1906, complaining of pain in the left temple and below the ear. He had had suppuration from the ear for a year and nine months, six months constant headache in the left temple and pain in the face; for fourteen days he had experienced some giddiness and enlarged tonsils, a limp in walking, constant high-pitched whistling tinnitus in the left ear which for four days had been very great. For six weeks there had been a large swelling in the face in front and below the left ear which had increased gradually; for one week the patient had been unable to swallow owing to pain in the act; for four weeks he had noticed that the face was drawn up on the right side; he had been unable to sleep for four nights on account of the pain; there had been no sickness. The man had been doing his work within four days of coming to the hospital. On examination there was a large tender swelling in the parotid region in front and below the left ear; there was complete facial paralysis on that side; a large polypus blocked the meatus; there was no tenderness or œdema over the mastoid or outer antral wall. There was difficulty in opening the mouth, but it could, however, be seen that the left side of the soft palate appeared full and the left tonsil was pushed downwards and inwards. The temperature was 97 and there was no mystagmus, optic neuritis, or paralyses. At the operation on the day after admission the outer wall of the antrum was dense and the cavity contained degenerated lining membrane and cheesy pus. The mastoid process was diplœtic and free from disease. On removing the polypus and granulations from the middle ear the upper and back part of the inner wall were found to be absent and the whole led upwards, backwards and inwards to a large cavity which should have been occupied by the vestibule and semi-circular canals. The cavity was freely exposed and was found to be full of granulation tissue among which was lying a sequestrum, consisting of part of the vestibule and parts of the opening of the semi-circular canals. The cochlea was intact. The anterior inferior meatal walls, both bony and cartilaginous, were represented by a ragged opening. On passing the finger through this opening it was found to lead to a cavity running down behind the jaw to the soft palate and tonsil which cavity was full of fœtid pus. In order to drain this cavity, an aneurism needle was passed to the bottom, its point after being turned up in the neck in a line with the mastoid process was cut down upon; the intervening structures were then carefully divided until the instrument was free. The cavity was well stuffed with iodoform gauze, and hot fomentations applied to the parotid swelling which, Mr. Cheatle said, was probably glandular in origin. Mr. Cheatle remarked that the case was interesting from several points of view:—(1) The absence of symptoms of labyrinthal disease in the whole history of the patient, and the fact of the man having been at work four days before admission; (2) the fact that there were no gross mastoid signs due to the anatomical condition, *i.e.*, the dense outer wall and the diplœtic mastoid process, also the intervening layer of dense bone between the cavity of the antrum and the mastoid process, a common anatomical condition which prevents suppuration reaching the surface, this condition being simply a continuation of that found in early infancy; (3) the track of the pus into the soft palate was unusual, having evidently come from the meatus behind the jaw to the soft palate. The patient's recovery was uneventful; the temperature never reached 100°, and he left the hospital at the end of January with everything quite healed. He reported himself at the end of February, having resumed work in the meanwhile. He experienced no inconvenience beyond facial paralysis and he was found to have some hearing in the left ear; the conversational voice was heard at fifteen inches, the watch at two inches and the acoumeter at four inches, demonstrating, as Mr. Cheatle pointed out, the interesting fact that the vestibule and semi-circular canals can be removed without complete loss of hearing.

TRANSACTIONS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

Meeting held February 8th, 1907.

The President, Mr. Clutton, in the Chair.

MEDICAL AND SURGICAL TREATMENT OF CONGENITAL PYLORIC STENOSIS.

Dr. G. A. Sutherland read a paper on

THE MEDICAL TREATMENT OF CONGENITAL PYLORIC STENOSIS.

The details of the treatment were given in connection with three cases. The aim of the treatment was to remove any source of irritation in the stomach that might maintain pyloric spasm and to keep the stomach free from any irritating food material which might excite pyloric spasm. For this purpose small feeds, frequent feeding, and food capable of being digested in the stomach were necessary. Fat was more irritating than any other constituent of food. Gastric lavage should be carried out daily at first, to prevent any retention of irritating food materials in the stomach. Progress was indicated by a cessation of vomiting, by the return of normal intestinal evacuations, by a diminution in the stomach peristalsis, by the disappearance of signs of distress and discomfort in the patient, and by improved nutrition. He had not found any benefit from treatment by sedatives, such as opium or the bromides, but advised the use of saline injections, both subcutaneously and per rectum, to supply the great need of water in the tissues generally.

Dr. A. F. **Voelcker** read a paper on

SOME CASES OF PYLORIC STENOSIS IN INFANTS.

He gave a brief description of seven cases that had been under his care in the past two years; five died. There had been altogether 39 cases in Great Ormond Street Hospital since 1897. Thirty-five of these were in males, four in females; in no instance had more than one case occurred in the same family; nine out of 34 were first-born children. Other congenital malformations occurred in only two cases. In 70 per cent. of the cases symptoms began between the second and fourth week; 21 out of 37 cases (56 per cent.) were in breast-fed children. Brown fluid was sometimes vomited, never bright blood. The gastric contents were acid and contained pepsin; 34 of the 39 cases (87 per cent.) died. Five were operated on; they all died. Vomiting was not an important point in either prognosis or pathology. He suggested that the condition might be an acquired one, due to some congenital perversion of the gastric juice.

Mr. F. F. **Burghard** read a paper on

THE SURGICAL TREATMENT OF CONGENITAL PYLORIC STENOSIS,

based upon 16 cases that had come under his own care. He pointed out that the chief difficulty at present was to know in what proportion of cases medical treatment alone might be expected to suffice. Whereas in former years most of the cases came under the surgeon's hands at an early date, the tendency at present was to delay operation as long as possible in the hope that medical measures alone would succeed. This hope was justified in a certain number of cases, and the debate would probably do much practical good by enabling surgeons to form some idea of results that were likely to follow medical treatment alone, as hitherto no extended experience had been published. Dealing with the question of operative results, 16 cases in all had been operated upon by the same method, namely, dilatation of the pylorus, and of these 11 had recovered satisfactorily from the operation, 10 remaining well, whilst one case died of convulsions within three months of the operation. The total operative mortality had been therefore 31.25 per cent., whilst the total mortality had been 37.5 per cent. The chief danger of the operation was shock, which could be minimised by careful preliminary preparation and operating rapidly in a well-warmed room. Two accidents that had happened in the series of cases quoted were rupture of the pylorus in two cases and wound of the duodenum in one. These accidents could be treated by immediate suture and were not necessarily fatal. Prolapse of the omentum and small intestines was a very troublesome complication, as it tended to prolong the operation, and this might quite well cause it to prove fatal. It was best avoided by making the incision high up in the middle line over the liver, which was hooked up to allow the pylorus to be pulled out of the wound and allowed to fall back into place at the end of the operation, so as to keep the omentum and intestines in place. The child was fed per rectum for twelve hours after the operation, after which feeding by the mouth was gradually resumed. Dilatation of the pylorus was contrasted with pyloroplasty and gastro-jejunostomy, and compared favourably with these on account of its simplicity and rapidity. No recurrence of symptoms occurred after any of these cases.

Dr. **Ashby** (Manchester) had treated 11 cases; they all died. Only one of them had been operated on. He had usually seen temporary improvement as a result of medical treatment, and had found whey of the greatest service in the feeding. The condition might deteriorate after all vomiting ceased. At the autopsies he had been struck by two points especially, first, the constant presence of marked gastric catarrh, and, secondly, the fact that the hypertrophy rarely caused complete obstruction. He thought that operative measures should be directed to the pylorus rather than to anastomosis.

Mr. **Clinton Dent** said that of 120 collected cases, including a number of unpublished ones, that had been operated on, the mortality was about 50 per cent. Surgeons rarely saw cases until the classical picture was fully established. He was against the performance of gastro-enterostomy, but thought that we should not confine ourselves to any one operation. He had a specimen in a seven months' fœtus, showing the condition well marked.

Dr. G. F. **Still** had seen 27 cases personally. Three had not been treated at all. In one the issue was unknown. Of the remaining 23, 14 recovered. Of these 14, 8 had been operated on, 5 of which were mild cases that he had passed on direct to the surgeon as had formerly been his routine custom; the other six had been treated medically, five by lavage, one by dieting only. Of the nine that died, three were untreated (moribund), three had been operated on, and three treated medically. He pointed out that the question of surgical treatment was not to be decided only by statistical mortality tables. He raised a query as to the late results of operative measures; on the other hand, lavage twice daily for months might be impracticable.

Mr. **Makins** had operated on two cases, and they both recovered, but one died later from enteritis.

Dr. **Edmund Cautley** considered that physicians were too optimistic in their views. He thought that many cases were diagnosed as hypertrophic pyloric stenosis that were really due to spasm and other conditions. In true hypertrophy nearly all the cases died unless operative measures, which therefore were absolutely imperative, were undertaken. Why was the condition never found at autopsies apart from cases recognised during life? Of twelve of his cases, nine had been operated on by Mr. Clinton Dent; none died, except for accidental occurrences, such as pneumonia, &c.

Dr. **Robert Hutchison** had seen nine cases in private practice. One was operated on and recovered. Of the eight treated medically, only one died. He thought that hospital cases did not do so well.

Mr. **Burghard**, in reply, said that in his experience hospital cases had done decidedly better.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

MEETING HELD FRIDAY, FEBRUARY 15TH, 1907.

The President, J. F. O'Carroll, M.D., F.R.C.P.I., in the Chair.

URINARY TUBERCULOSIS.

Dr. L. G. **Gunn** exhibited a specimen taken from a man of about forty-five years of age, who had been admitted to hospital with the usual symptoms of urinary tuberculosis. As far as they could diagnose, he had a large right kidney, from which it was thought the pus in the urine was probably proceeding. The bladder was small, contracted, and tubercular. A cryoscopic examination led to the conclusion that the patient was on the borderland of insufficiency, and the right kidney was thought to be a bag of tuberculous pus. On operating, a large kidney was found having a great deal of apparently healthy tissue in it. On exploring the pelvis of the kidney, tuberculosis was found present. He presumed he had been wrong in thinking the other kidney healthy; he therefore did not take the kidney out. The patient died two days afterwards, and the post-mortem showed that the cause of death was extensive miliary tuberculosis affecting the liver, lung and spleen. The other kidney was a tiny structure, apparently congenitally small, but perfectly healthy, though incapable of sustaining life. The primary tuberculous focus was a small chronic abscess in the prostate.

The **Chairman** said the fundamental interest in the case was the difficulty of making out whether one or other or both kidneys were involved. For many years attempts had been made to settle the matter. An observer had stated that the mere palpation of a healthy kidney was sufficient to produce some degree of albuminuria; a larger amount was produced if the kidney had been damaged previously; but if it were an utterly insufficient thing like a tuberculous mass it did not produce any. If that were established, it might give them a further and pretty commonplace test for which of the two kidneys was involved.

Professor **McWeeney** said the large kidney was a beautiful specimen of compensatory hypertrophy; the other was the smallest he had ever seen which bore no evidence of organic disease.

Mr. **Gunn** replied.

(1) LIVER WITH CIRRHOSIS AND CARCINOMA; (2) A CASE OF LYMPHATISM.

Dr. A. R. **Parsons** showed specimens of above. The first was the liver of a woman, æt. 42, who had been admitted to hospital in November last complaining of considerable swelling of the abdomen and also of the legs. The swelling of the abdomen, which had commenced three months previously, had not interfered with her until some six weeks before admission. Her previous history threw practically no light on the nature of the swelling, excepting in the one point that had a slight bearing on it—viz., that five years previously she had had a slight attack of hæmorrhoids. She was the mother of twelve children, of whom six had died in infancy. She was rather a sallow woman, but not jaundiced. Opinion differed on the ante-mortem diagnosis as to whether the condition was malignant; he held the view that it was cirrhosis, basing his opinion on the facts that the patient gave an ill-defined history of alcoholism; the liver was uniformly enlarged; the spleen was considerably enlarged; there was a history of hæmorrhoids; and the fluid obtained on tapping was clear and non-sanguineous. On the other hand, the rapid emaciation and short history of the case were supposed to suggest malignant disease. No primary focus could be palpated in any part of the abdomen. She vomited, but no hydrochloric acid was present. There was no symptom to suggest primary disease of the stomach. On opening the abdomen after death they found the liver considerably enlarged, and it was perfectly manifest she had malignant disease of the liver. It was equally certain she had advanced cirrhosis of the liver, usually attributed to alcoholism. A careful examination was made of the stomach, pancreas, intestines, uterus and ovaries; there was no evidence whatever of primary malignant growth in these organs, and the naked eye appearance of the liver, and the microscopic sections, showed that the growth was primary in the liver. There were secondary nodules in the lung. The case represented an unusual combination of primary malignant disease and advanced cirrhosis of the liver.

Dr. A. R. **Parsons**, in presenting his second specimen, said that in 1892 he had met with several cases of sudden death in children from one to five years of age, in which the only abnormal post-mortem appearance was great enlargement of the adenoid tissue of the intestines. Dr. Peacocke had described two or three cases which were identical with his own cases, and referred to a valuable paper by Dr. Ewing, of New York, who, following Paltauf, called the condition lymphatism. The cases were characterised by sudden death, frequently, but not always, preceded by convulsions; and the post-mortem revealed nothing sufficient to account for death. In the cases which he (Dr. Parsons) had met, he noted considerable enlargement of the solitary follicles and Peyer's patches; considerable enlargement of the mesenteric glands; the spleen was slightly enlarged, and a section of it showed some enlargement of the Malpighian bodies. Dr. Peacocke observed in his cases extreme enlargement of the thymus gland. Since Dr. Peacocke observed his cases no others had been reported in Dublin, and there was little information available in English literature. It was not until recently that he had had an opportunity of seeing another case of lymphatism. This was a child of seven months. He was perfectly well until the Saturday; he was brought to hospital on the Sunday at 12.30, and died at two o'clock. Simultaneously he (Dr. Parsons) had a child in hospital suffering from pneumonia. He was the same age as the other child. The viscera of both children formed a striking contrast. In the one the thymus gland was in its presumably normal condition; in the other there was an enormous enlargement covering quite a large part of the heart. It was, he thought, quite possible that a large number of cases succumbed to the condition of lymphatism, and not to convulsions.

Dr. **Pringle** and Dr. **Farnan** cited similar cases.

Dr. **Peacocke** said that when he was observing his cases he was anxious to get comparisons similar to what Dr. Parsons had got, as he felt that exaggeration was possible. He had never found any enlargement of the external lymphatic glands. He had, however, found a slight patch of congestion at the base of one or both lungs, although there was no evidence of there being anything wrong before, except a slight cold. He was sure a great many cases occurred which were ascribed to convulsions, which, however, was only a symptom of disease—not a disease itself.

Dr. **McWeeney** recalled a case similar to Dr. Parsons' first exhibit. As regards the subject of lymphatism, he did not think they had good scientific proof that death was due to the lymphatic condition.

Dr. Parsons, in replying, admitted they were not able to trace the connection between the lymphatism and sudden death, but the fact remained that the condition was found present in the cases of sudden death which he had cited, and as cases accumulated there would be fair reason to believe that there was some connection.

ORGANISMS FROM CEREBRO-SPINAL MENINGITIS.

The **Secretary** (Professor White) exhibited specimens of organisms obtained from cases of cerebro-spinal meningitis. From the first case reported he had, he said, made direct cultivations from spinal fluid obtained aseptically by lumbar puncture in broth, human blood serum, glycerine agar and litmus milk. The broth next day was barely clouded; tiny discrete grey colonies developed on the serum; the glycerine agar remained sterile. Subsequent examination showed these growths to be pure cultures of a diplococcus, sometimes seen in tetrad form, staining irregularly with simple stains like Loffler's blue and negative to Gram's stain. Microscopic examination of the cerebro-spinal fluid showed very many pus corpuscles and numerous organisms seen mainly as diplococci, but there were many tetrads and a few short chains. A considerable number of these organisms were inside the pus cells. Some of them appeared to have capsules, and like those in the cultures all were decolorised by Gram's method. He inoculated further cultures from the originals, and continued the inoculation to the fifth generation, which was still alive. The fourth and fifth had grown very well on ordinary agar, although the original inoculation on the glycerine agar was without result. He had done animal inoculations with negative results. The same organism in pure culture was obtained from later cases of the disease, but a smaller number of pus cells and fewer organisms were present, although the cases were more severe clinically. The diplococcus now exhibited had many of the characters of the organism described by Weichselbaum under name, *diplococcus intracellularis meningitidis*, but apparently differed from it in having a capsule, and in forming short chains. He was not quite satisfied that the organism was a distinct entity, but inclined rather to the opinion that it was a modified *pneumococcus*. That, however, was difficult to prove. In a previous outbreak he only got the pneumococci from a great many cases, and during that outbreak in only one case did he get an organism which, like those now exhibited, might be classed with Weichselbaum's.

Dr. **Day** gave the clinical history of four cases, the curious thing about them all being, he said, that they were perfectly clear in their intellect.

Professor **McWeeney** had observed two meningitis cases within the last few days from the Children's Hospital, Temple Street. A post-mortem was obtained in the first case, and revealed the tubercular form, limited to the cerebral pioarachnoid. From this numerous T. B. were obtained in smear preparations. A curious fact was that whilst engaged in searching through preparations of the membranes of the cord he came across a single polynuclear leucocyte, containing a few typical "biscuit-shaped" diplococci. Was it a case of mixed infection? In the second case, which was regarded by Dr. D. Farnan as typical cerebro-spinal meningitis, there was no autopsy, but he had examined about 5 cc. of fluid obtained from the child (æt. 3) by lumbar puncture. The microscopic result was negative, but he had succeeded in growing from it, as the only organism present, a gram-staining diplococcus tending to form tetrads, and growing well in the form of small whitish colonies on ordinary agar, serum-agar and blood-agar. He felt sure this could not be the organism described by Weichselbaum and found by Professor White. The speaker concluded by referring to the probability that the organism obtained access *via* the posterior fossæ of the nose, to its propagation by contacts, to its low resisting power, and to the small numbers in which it occurred even in severe cases. He could only suppose that it must be highly toxic, though of this there was no experimental evidence.

Dr. **Farnan** read the clinical history of the cases mentioned by Dr. McWeeney from notes by the house surgeons.

Dr. Parsons and the Chairman also spoke, and Professor White replied.

LIVERPOOL MEDICAL INSTITUTION.

Meeting held Thursday, February 28th, 1907

The President, Mr. **Frank T. Paul**, F.R.C.S., in the Chair.

CLEIDO-CRANIAL DYSOSTOSIS.

Dr. **J. Hill Abram** showed a typical case of the disease described by Maire and Sainton under the name of cleido-cranial dysostosis. The patient was a boy, æt. 16. The clavicles were absent, the cranium typically brachycephalic and the anterior fontanelle still largely open. The distorted vertex with the deficient development of the facial bones led to a superficial resemblance to cretinism; the absence of any solid œdema in the subcutaneous tissue and the considerable standard of intelligence attained showed that cretinism might be excluded.

Dr. **A. G. Gullan** said that certain features led him to believe that the lad was to a certain extent a cretin, viz., the full face, arched eyebrows, thick neck, short stature, lordosis of the spine and the typical waddling gait, full abdomen with unfolded umbilicus, undeveloped genitals, and absence of hair from the pubis, the coarse hair of scalp, and characteristic broad hands all pointed to a degree of athyroidism. The lad, though intelligent, was certainly emotional. Dr. Gullan considered that the combination of cretinism and the absence of the clavicles made the case even more interesting.

RECURRENT PARALYSIS OF OCULAR MUSCLES.

Mr. **R. J. Hamilton** showed a case of recurrent paralysis of the ocular muscles in a man, the subject of hæmophilia. The condition was always preceded by severe headache which lasted for some hours, and the paresis lasted from four to six months. The first attack occurred four years ago and followed a very severe and almost uncontrollable hæmorrhage, the result of tooth extraction. Mr. Hamilton suggested a neuritis, induced by the severe anæmia as a possible explanation of the paralysis.

Dr. **K. Grossmann** agreed with Dr. Hamilton that the case was one of peripheral (neuritic) origin. He had recently observed a similar case occurring after influenza, recovering and reappearing after a second attack of influenza. The second attack of paralysis recovered and recurred finally got gradually well. Similar post-influenzal neuritic attacks followed by alternate improvement and relapse had been observed in other parts of the body.

Sir James Barr and Mr. T. H. Bickerton also spoke.

CATARACT EXTRACTION.

Mr. **Richard Williams** read a note on cataract extraction mainly in reference to suppuration in the wound, and reported the case of a gentleman, æt. 88, in which the suppurative process had been arrested by the application of a 1 per 1,000 solution of perchloride of mercury after a weaker solution (1 in 3,000) had failed. He suggested that these cases were not due to the introduction of infective material from without, but to abnormal activity of the ordinary micro-organisms of the conjunctiva in certain abnormal conditions of the nervous system.

Dr. **K. Grossmann** said suppuration was fortunately very rare and when it did occur there would always be a suspicion that that infection had come from without. An inspection of the wound six hours or so after operation was generally desirable, especially after extraction without iridectomy.

Mr. T. H. Bickerton, Mr. E. M. Stockdale, and Mr. R. J. Hamilton also spoke.

MALARIA.

Dr. **J. Lloyd Roberts** read a paper on malaria, based on the study of 124 consecutive cases under his care in the tropical wards of the Royal Southern Hospital. He gave a brief historical survey of the advance in knowledge of this disease during the last twelve years, and gave proofs of the correctness of the mosquito-malaria theory. The ætiology of malaria was then considered and the life history of the various kinds of parasites met with in man was described, with lantern illustrations of each at varying stages of its existence. The correlation between their life-cycle, and the clinical symptoms was demonstrated. Lantern slides were shown of the temperature charts of the different kinds of malarial fever—benign tertian, quartan, malignant tertian and malignant quotidian—and the diagnostic differences between the benign quotidian and the malignant quotidian charts were pointed out. The symptoms of the disease were next described, and the diagnosis considered with reference to the history, source of infection, physical examination, type of fever, anæmia, leucopenia, great proportional increase of the large lymphocytes and particularly the discovery and recognition of the parasites and of the pigmented leucocytes. Cases were mentioned illustrative of the differential diagnosis between malaria and such diseases as phthisis, suppuration, ulcerative endocarditis and hepatic abscess.

Dr. **W. Carter** thought that the time had come when the word "malaria" which kept the superstition that bad air caused the disease should be abandoned for a name more in accordance with absolutely established facts. Among the unsolved problems of the disease were:—(1) the occurrence of attacks years after removal from mosquito-infected areas; (2) the apparent immunity of exceptional individuals, even after repeated bites; (3) the impossibility, in some cases, of administering quinine owing to its effects being more poisonous than those produced by the parasites. Among the more troublesome symptoms were (1) the occasional occurrence of persistent vomiting, rendering it necessary to administer the quinine by rectum or hypodermically; (2) the supervention of coma, which in his experience was best relieved by freely blistering the shaved scalp, unless (3) it was accompanied by a continuous and very high temperature, when cold baths were in addition required. In some cases of chronic cachexia, with acute exacerbations, the utmost benefit followed a course of Warburg's tincture when quinine in other forms could not be borne or failed to relieve.

Dr. C. J. MacAlister, Dr. Bradley Hughes, Dr. W. T. Prout and Dr. Wyley also discussed the paper.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD AT LIVERPOOL, FEBRUARY 15TH, 1907.

The President, Dr. E. O. CROFT (Leeds), in the Chair.

CARD SPECIMEN.

DR. A. STOOKES (Liverpool) showed a mixed adenoma and dermoid of the ovary, weighing 9 lbs. co-existing with a small dermoid of the opposite ovary.

SPECIMENS.

Drs. BRIGGS and EMRYS-ROBERTS exhibited (*a*) the Fallopian tubes and ovaries from a case of acute gonorrhœal salpingitis, occurring in a woman æt. 25, who had suffered from repeated attacks of pelvic pain since marriage, 5 years ago. (*b*) Cancer of the cervix uteri coincident with unilocular cyst of one ovary, and fibroma of the opposite ovary, removed from a patient, æt. 67, iv.-para, who had suffered from a sanious vaginal discharge for two years. Abdominal hysterectomy was performed. Microscopically the growth was an epithelioma.

Dr. GEMMELL showed a double pyosalpinx. The tubes were each 4 inches long and 1 inch in diameter. There were only a few peritoneal adhesions. The ovaries were unaffected.

Dr. A. STOOKES (Liverpool) exhibited an ovarian cyst with the adherent vermiform appendix successfully removed by abdominal section from a nulliparous woman, æt. 41, who had suffered from pain in the right side and menorrhagia for 6–7 years. The Fallopian tube was thickened by chronic salpingitis, and was stretched over a thin-walled cyst of apparently inflammatory origin. Beneath this lay the cystic ovary the size of an orange. The adherent vermiform appendix was also removed.

Dr. F. W. BAKER YOUNG (Liverpool) showed a safety-pin removed from the vagina of a girl, æt. 8. It had been there for two years and had caused continuous hæmorrhage.

Dr. DONALD (Manchester) described a case of ectopic pregnancy co-existing with uterine pregnancy in a woman æt. 40, iv.-para. Previous to this pregnancy, menstruation had been regular every four weeks, lasting one to fourteen days. She was delivered of a 7-months living child, eight weeks prior to admission to hospital. Three days after the confinement, her doctor noticed an abdominal swelling which increased in size and was accompanied by intermittent cutting pain in the left side. During the eight weeks following delivery there were two menstrual periods lasting seven and fourteen days respectively, the, latter accompanied by the passage of two large stringy lumps. There were no symptoms of severe pain, fainting, or other signs of hæmorrhage. An irregular swelling occupied the hypogastric and both iliac regions, and per vaginam was found to be distinct from the uterus. Abdominal section revealed a sac composed of the left Fallopian tube, containing a decomposing fœtus measuring 13 inches and weighing nearly 3 lbs. The sac was adherent to intestine, and was therefore stitched to the edges of the abdominal wound, and packed with gauze. The patient was discharged convalescent at the end of six weeks. The extra-uterine was probably synchronous with the uterine pregnancy, death of the fœtus occurring when the uterine fœtus was born.

Drs. GEMMELL and LEITH MURRAY showed a tumour of the right ovarian ligament weighing 2 lbs. and the size and shape of a cocoanut. There was a double twist of the pedicle, and the surface and substance of the tumour was deeply mottled with hæmorrhage. Microscopic section proved it to be a pure fibroma.

Dr. STOOKES (Liverpool) also described a case of fatal vomiting in a woman ii.-para, who was seven months pregnant. From the second to the sixth month the vomiting was not excessive, but for the fortnight preceding admission to hospital it was continuous and "coffee ground" in character. She was so ill that induction of premature labour was deemed inadvisable. Rectal salines were administered. Death occurred on the second day after admission from cardiac failure. At the autopsy partly digested blood was found in the stomach and small intestine, and the kidneys were congested, the other organs were normal.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, March 10th, 1907.

FIRST SIGNS OF PHTHISIS.

THE difficulty in diagnosing phthisis in its germinal period is well known and frequently impossible for the general practitioner. It is true some methods, such as Rontgen Ray diagnosis, the chemistry of respiration, modifications of the humours, cyto- diagnosis, etc., have been tried by some new lights, but they are beyond the reach of the multitude. However, Dr. Barot has made a study of certain clinical signs that are sufficient to reveal tuberculosis at its inception, and these he divides into two groups. The first are composed of what he considers cardinal signs, and are constant. They are four in number:—(*a*) Wasting. This sign is not absolutely pathognomic, but it is supported by the presence of the three others. (*b*) The second sign is a sensation which also belongs to neurasthenia, but is nearly always present in incipient pulmonary tuberculosis. It consists in an invincible lassitude experienced in the morning. Instead of being refreshed from the night's rest the patient feels more tired getting up than when he laid down. (*c*) The third sign to which M. Barot calls particular attention because it is new and seems to be special to the disease is a painful sensation to pressure, localised at two distinct points: along the line of the spinous processes, the apophyses, and in the sterno intercostal spaces. The vertebral sensitiveness involves one or more apophyses; under moderate pressure the sensation provoked is disagreeable, under stronger pressure it is acute enough to make the patient cry out. M. Barot attaches considerable importance to this sign, as he found it in no other affection, acute or chronic, foreign to the baccilli of Koch. The painful sternal points correspond exactly to the vertebral points. (*d*) The fourth sign, like the third, is important as well as new, and consists in an abnormal and rough resonance of the voice when the patient speaks in a low voice, and can be heard over the vertebral painful points; it differs from the same sounds in the healthy individual which are soft and similar to the vesicular murmur. Such are the four clinical signs considered by M. Barot as constant and sufficient to establish the diagnosis of consumption in its germinal period, and should be sought for in every suspicious case, and the more so as it is at this stage that a well-ordered dietary and an enlightened treatment are attended with the best results.

CAUSES OF SUDDEN DEATH.

For press reporters—and for doctors sometimes—the diagnosis of heart disease or congestion of the brain is always sufficient to explain sudden death. Yet out of 1,000 post-mortems, says Professor Duise, scarcely one real case of heart disease is found, while cerebral congestion is frequently the outcome of a fanciful imagination.

In reality the cases in which sudden death occurs are numerous. In the absence of traumatism, sudden death may occur in the course of maladies unaccompanied by any marked symptoms.

Sudden death, said M. Bruardel, is the rapid and unforeseen termination of an acute or chronic malady developing frequently in a latent manner. It is an unexpected end to an ignored or unknown disease. An individual dies from the heart, the lungs, the brain and, above all, from the kidneys.

Microscopic examination of the viscera will not explain the real cause of death in 10 per cent. of the cases.

The classification of the multiple causes of sudden deaths adopted by Prof. Duise embraces the circulatory, cerebro-spinal, respiratory, digestive and genito-urinary apparatus.

Heart.—Chronic disease, arterio-sclerosis of the coronary arteries, aortic and mitral insufficiency, fatty degeneration and sclerosis. Paralysis of the heart in convalescence from diphtheria or croupous pneumonia.

Arteries.—Congenital narrowness of the aorta. Rupture of aortic aneurism, arterio-sclerosis of the encephalic arteries (apoplexy) or thrombosis (softening).

Veins.—Rupture of a pulmonary vein near the auricle, rupture of the azygos into the right pleura, of the inferior cava (the result of a violent struggle or effort).

Phlebitis(clots passing into the circulation and producing mortal thrombus of the pulmonary artery). Latent thrombi of the meningeal sinus and venous thrombi after fractures.

Cerebro-spinal apparatus.—Thrombi of the large cerebral arteries, cerebral tumour, latent abscesses of the brain revealed by post mortem. Epilepsy, slight violence over the epigastric or laryngeal regions.

Pulmonary apparatus.—Bursting of a large vessel in hæmoptysis. Granular phthisis without any special symptoms, producing sudden death from œdema of the lung.

Ambulatory pneumonia with decrease of temperature (aged persons and hard drinkers). Thrombus of the pulmonary artery. Ambulatory diphtheria: patients found dead in the morning who seemed to be but slightly indisposed the preceding evening (croup descending the bronchi), œdema of the glottis in the course of tonsilitis; bronchial catarrh of young children.

Digestive apparatus.—Abundant hæmatemesis from round ulcer of the stomach. Perforation of the ulcer with acute peritonitis. Mortal hæmorrhage from latent tumours of the stomach. Tuberculous or cancerous ulcers of the intestine or hæmorrhage. Perforating syphilitic ulcers of the rectum (women). Strangulated hernia not recognised by the patient, invagination and volvulus discovered at the autopsy.

Genito-urinary system.—Vesical tumours hydronephrosis producing acute uræmia.

Of all sudden deaths that by the kidney, according to Prof. Bronardel, is the most frequent, and the exciting cause is to be found in the different forms of uræmia: pulmonary form (dyspnœa, œdema), gastro-intestinal form (cholera nostras), alcoholic form in drunkards.

Sudden death has been observed in the course of extra-uterine pregnancy or in abdominal collapse after a few hours.

GERMANY.

Berlin, March 10th, 1907.

At the Verein für Innen Medizin, Hr. Litten spoke on

CONTUSIONAL PNEUMONIA.

He said that he had introduced the subject twenty-five years ago at the Medizinische Gesellschaft, and based it on fourteen cases. Liman then expressedhis satisfaction that this had been done, and said that by these clinical observations pathologists were in a position to take up a more precise ætiological standpoint, and Falk reported on pneumonia resulting from maltreatment of the thorax. Since that time the subject had not been again discussed at the Medical Society.

The speaker had then discussed the matter clinically only; he now proposed to discuss it from the point of view of professional opinions by the medical referee. He had not since then made any fresh observations, but he had thoroughly exhausted the teaching of the facts that had been sent to him for the purpose of obtaining expert opinion. The immediate reason for the present paper was two cases that were recently observed. The history of one case was as follows:—A man fell from a ladder from a height of some metres, striking his thorax on a piece of wood in the fall. Immediately afterwards he became pale and giddy and vomited. Brandy and water was given him and he recovered enough to be able to go home. He felt ill that and the next day, and on the following one had a rigor, and the same evening was seen by a medical man, who diagnosed pneumonia. On the fourth day the symptoms were grave, and on the fifth the man died. The club surgeon gave the opinion that it was remarkable that a young man should die so rapidly of pneumonia; it might have been a case of contusional pneumonia. The trade society demanded an opinion from an official surgeon,who gave the opinion that there was no connection between the accident and the pneumonia, that no external signs of the accident were visible. The pneumonia arose from other causes and the pension to the man's representatives was refused. This decision was contested, and the speaker was appealed to for a superior opinion. This was given to the effect that a connection between the accident and the pneumonia might be assumed with certainty and that the claim of the deceased's representatives was a proper one. This was the decision of the Court.

He preferred the expression contusional pneumonia in place of that of traumatic pneumonia, as the physical force was a "dull" or "blunt" one that led to compression of the pulmonary tissues. In these cases marks were scarcely ever seen externally, even when the lung tissue or heart was lacerated. The pneumonia did not occur where the contusion had taken place, not even on the same side. It was to be observed that tuberculous infiltration formed a place of lesser resistance. Contusional pneumonia affected people of younger years, who by preference had to perform heavy tasks. As regarded the immediate cause it was always a fall, a blow, being run over, injury from kneeling on the thorax, etc. The second case was specially noteworthy ætiologically. A carriage weighing 30 to 35 cwt. was off its frame and was being lifted on again by four men. One of the men immediately afterwards fell (March 20th) and had to be carried home. On the 22nd he had pneumonia, and on the night between the 23rd and 24th he died. The medical attendant had conceded in his report the connection between the injury and the death and admitted the claim for compensation on the part of the relatives. The official medical referee had, however, denied that there was any connection. The speaker was appealed to for a superior opinion (obergutashten). He was for the connection and confirmed the first opinion. He did not know then what the judicial decision had been. He had had three other cases before that of fatal pneumonia which had followed in a short time on the lifting of heavy weights. In one case the man had hæmoptysis immediately afterwards. For the rest it was not always a pneumonia, strictly speaking, but rather a hæmorrhagic infarct was formed. A case of importance was recorded as the Berlin Medical Faculty had given an "opinion." The case was that of a temperate young man. On May 25th, 1901, a heavy stone flag, weighing 5½ cwt., was being lifted. One of the workmen suddenly dropped his lever, complained of pain in the chest, and spat up blood. On the 27th pneumonia had developed and the patient died soon afterwards of gangrene of the lung. Two "opinions" had been given that there was no connection between the lifting and the inflammation. A "higher opinion" of Revers was to the effect that there was no bruising of the chest, and that the possibility of the healthy lung tearing could not be conceded. The Berlin Medical Faculty was now called on for its opinion. This was given by V. Leyden and Kraus, and was to the effect: (1) That other cases were already known in which pneumonia had followed the carrying of heavy weights; (2) the case must be looked upon as one of contusional pneumonia and a connection between the lifting and the pneumonia was in a certain degree probable. The speaker confessed that he did not understand this expression. After the premisses the strict concession of a connection would have been logical. As regarded the circumstances under which in lifting heavy weights tearing could occur he was of opinion that it could easily take place on deep inspiration. He had claimed that the earlier the pneumonia came on after the straining the more likely was the connection between the two; he had fixed the intervening period at two days. Aufrecht and Buch-Hirschfeld had given eighty hours in one case. He had himself now lengthened the period to four, five, or six days. Later occurring cases had been reported. One patient after an injury was brought home, felt ill the first day or two, but was not confined to bed, and even worked a little. On the sixth day he had to take to bed, and on the ninth a doctor was called in, who found pneumonia of a whole lung; which on the tenth day proved fatal. In another case a block of stone weighing 10 to 12 cwt. fell against a man's chest. He went pale, was taken home, and again did a little work. Ten days afterwards pneumonia and pleursy were diagnosed, and four days afterwards he died. Senator gave the opinion that the pneumonia had already existed four or five days when the man was first seen, and that the disease was certainly connected with the accident. Senator added that even in a less probable case the death must be attributed to the accident happening to an already weakened body. V. Leyden went farthest, however. A workman fell from a ladder, he still worked a fortnight, then got pneumonia and died. V. Leyden assumed a connection between the accident and the disease. In the speaker's experience pneumonia already present was influenced for the worse by the traumatic shock. As no certain day could be named as that on which contusional pneumonia would arise, each medical referee must decide for himself. But it was necessary in coming to a decision not to satisfy one's self with a *non-lignet*; the judge would then not know where he was. As regarded the man's doings between the accident and the disease, there was no normal condition; one man worked on, another ceased work, another worked with interruptions.

As regarded symptoms, they did not differ from those of ordinary pneumonia. Hæmoptysis was perhaps a characteristic. This was often very diffuse and arose from the laceration of lung tissue. Recovery generally took place. There was one death in his fourteen cases.

AUSTRIA.

Vienna, Mar. 10th, 1907.

Tænia Cucumerina.

At the Gesellschaft, Pollak showed a six months' child which for the last four months had been passing by the bowel daily small reddish white bodies about 1 centimetre long, and two broad, having all the appearance of miniature gherkins. The microscope revealed their nature to be segments of the Tænia Cucumerina, which is often found in the alimentary canal of the dog and cat, but rarely to be met with in the human being. The etiology in this case is somewhat interesting. When the child was five weeks old the mother with the infant went to visit a friend of the family who had a cat that lay in the bed with the infant. Three weeks after this occurrence the first segment was observed to pass from the child, which Pollak considers the necessary period for the growth of the worm from the ovum. The presence of the entozoon had no untoward symptoms, the infant remaining healthy and well. With the object of removing it from the canal he proposed to use kamala the dose of which is from 0.5 to 2.0 grammes; failing in this he may try Ext. Filicis Maris in cautious doses.

Digital Malformation.

Homer next produced a patient with a malformation of the left hand, that led to a wrong diagnosis of the initial stage of tabetic paralysis from the thickening of the left thumb. It appears that the patient was born with an abnormally long index finger, which gave trouble and was partially removed 28 years ago, owing to its excessive length. The cicatrix can yet be seen. The thickening of the thumb, which is only in the soft tissue, seems to be connected with this cosmetic operation.

Functional Treatment of Pes-Varus and Valgus.

Semeleder treated the members to a long and comprehensive method of treating flat-foot and club-foot without any surgical operation. He presented examples, very wonderful in themselves which had been corrected by his functional or automatic method and the assistance of a shoe which he has ingeniously devised for this purpose. The body weight is the chief factor in the production in the pes valgus and varus. Remove this, he affirms, and you prevent the deformity. With this origin in view, he arranged a boot with a lever at the sole of the foot and another in the upper part of the leg, making the angle of projection the fulcrum. In the standing or walking posture the weight bears on the horizontal bar, which turns on the "hypomochlion" that adjusts the distortion.

The first patient was a heavy person of 120 kilograms, or 18.8 stones, who had suffered, according to photo, very badly from pes valgus but now by this functional method was quite restored and lay in the normal position. The second patient was one that had been quite unable to walk without great pain. With this shoe he was able to move about without the slightest pain after a few days. At the same time, the twisted foot was adjusted and within six weeks was almost restored to its normal position and could move about without an instrument, free from pain. The third was a paralytic form of talipes valgus, which had been corrected by the same method. Eiselsberg thought this method of treating talipes was an excellent form of therapy and hoped that all the results would be verified by other favourable results. Handek thought this was Baly's idea improved on, the principle of twisting the deformed part into position. He was of opinion that the tests exhibited were not sufficient. Hovorka remarked that three years ago the "supinationsbrett" was introduced with great benefit in talipes, but Semeleder's instrument had the advantage of turning the foot into the correct position at every step the patient took. Friedländer expressed great satisfaction with Semeleder's method, which he had practised in Wilhelm's hospital with excellent results.

The Commission of Inquiry into the health of Belfast, appointed by the Local Government Board for Ireland, commenced sittings on March 5th, under the presidency of Colonel Harding, ex-Lord Mayor of Leeds. The other members of the committee are Dr. L. W. Darra Mair, one of the medical staff of the Local Government Board, England; Dr. K. Chalmers, medical officer of health of Glasgow; Mr. P. C. Cowen; and Colonel Dr. E. Selim, of the British Local Government Board, with Dr. T. P. Nolan as secretary.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Presentation to Sir Henry D. Littlejohn.—An interesting ceremony took place in the Hall of the Royal College of Surgeons on March 8th, on the occasion of the presentation to Sir Henry Littlejohn of his portrait, painted by Sir George Reid, R.S.A. In making the presentation, Lord Stormonth Darling said that the confluent streams of medicine and of law met that afternoon to do honour to their old friend and teacher, Sir Henry Littlejohn. Those of them who had been law students had reason to look back with satisfaction to the days they spent in the little room in the Police Office under the tuition of Sir Henry. Personally, he had never learned so much in so short a time from any other teacher. They all knew the extraordinary vivacity and humour, and, above all, the clearness with which he explained the subjects he dealt with. In the discharge of his duties as Police Surgeon and Medical Officer of Health, Sir Henry had won golden opinions, and had come to be looked upon as a leading medical expert. Dr. John Smith, speaking as the oldest medical friend of Sir Henry, referred to the esteem in which the latter was held. It was unnecessary to do more than recall the eminent services Sir Henry had rendered both in a civic and academic capacity, and to contrast the sanitary condition of the town now with its condition when the medical officer of health first took up his duties. Virtue was doubtless its own reward, but this was an occasion for showing in a tangible form their appreciation of services rendered. Sir Henry Littlejohn in reply said that the present was a most flattering incident in a busy life passed amidst those keen critics, his medical and legal brethren, in a great centre of medical and legal education. He had lived, so to speak, in the open air, and he had to acknowledge the unvarying indulgence shown him by his medical brethren in the discharge of the delicate duties of police surgeon and medical officer of health. On looking back over a long series of years, he was not conscious of ever having made an enemy. Sir Henry then spoke of his alarm when he had heard that he was to have his portrait painted, and his pleasure when he found that the distinguished artist made the twelve sittings a pastime with his varied talk and vivid memories of the great men who had sat to him. He was proud in possessing such a portrait, and should have pleasure in passing it down to his family. Amid great discouragement he began the practical teaching of forensic medicine, and for forty years taught it with increasing success in one extra mural school. He could easily recount the changes he had witnessed in the Courts of Law and Municipality during a long life, and he had often been asked to write reminiscences of life and character in his native city. But, alas! he found that he, too, often had to deal with the painful and tragic in domestic life, and that the events were too recent to justify him in drawing aside the veil that must, for a time at least, be left untouched. He solaced himself with memories of friends whose cheerful intercourse had gladdened his life and had left him the pleasant heritage he could maintain in his old age—a pleasant demeanour and a cheerful countenance. Old age, did he say? He would rather repeat the words of Sir William Turner—"perpetual youth." He had enjoyed an unusual spell of long life and good health; but thrice (would they believe it?) had the startling words *mene mene, tekel, upharsin* been thrown on the screen of his life to his saddened gaze. On three occasions he had been sentenced to death by distinguished medical men, who had reported to their respective insurance companies that that poor fellow Henry Duncan Littlejohn was a bad life and would soon shuffle off this mortal coil. He had had the melancholy satisfaction of following the remains of these doctors to the grave. The meeting had given him a fresh lease of life, and he hoped with cheerful heart, God willing, to live on to the end of his natural life. The ceremony was attended by a large number of Sir Henry's friends and admirers, including the President of the two colleges, many of the Lords of Session, members of the bar, the university, and the legal and medical professions.

BELFAST.

The Samaritan Hospital.—The annual meeting of this institution was held last week, the Lord Mayor (the Right Hon. the Earl of Shaftesbury, K.C.V.O.) presiding. Dr. John Campbell read the medical report, which showed that during the year 526 patients attended the extern department, and 176 were admitted to the wards. The operations numbered 144, and there were seven deaths, six after operation and one from inoperable cancer. The surgeons regretted to report that on several occasions they had to refuse patients admission owing to lack of funds.

The Health Commission.—During the past week the much-talked-of Health Commission has begun its sittings, and has continued on four days to inquire into the health problems of the city. The Commissioners are Colonel Harding, ex-Lord Mayor of Leeds; Dr. Chalmers, medical officer of health, Glasgow; Dr. Mair, a medical inspector of the English Local Government Board; Surgeon-Colonel Flinn, who holds a similar post under the Irish Board; and Mr. P. C. Cowan, chief engineering inspector under the Irish Local Government Board. Day by day the large committee room of the City Hall has been crowded with City Councillors, Water Commissioners, members of the Citizens' Health Committee, and others interested in the inquiry. Counsel have been employed by some of the bodies interested, but will not be allowed to cross-examine witnesses. The examination is on oath. The first witness was the Registrar-General for Ireland, who gave evidence regarding the population of Belfast and the death-rate. Owing to the rapid increase of population it is uncertain what the exact population is, and, of course, the death-rate varies with the different estimates made. It is probably about 380,000. After Mr. Meyer, the assistant town clerk, had given some formal evidence, the Chairman of the Public Health Committee, Dr. King-Kerr, was examined at length. This is the gentleman who has had the most acute differences with his professional brethren during the past year, as they consider that he is largely responsible for the appointment of the present medical officer of health. He gave evidence regarding the distribution of insanitary areas in the city, the working of the refuse destructor, the provision of hospital accommodation for infectious cases, and some minor points. No doubt he will be heard again, as much of his evidence will be traversed by medical and other witnesses representing the Citizens' Association, the Ulster Medical Society, and other bodies. For three days Dr. W. H. Bailie, the medical officer of health, was submitted to a searching examination, and even those who most strongly opposed his appointment to his present post last year were sorry for him in his most unenviable position. Of course the first points brought out were that he had been a general practitioner and a member of the City Council, and had no previous experience of his special work. Question after question was put to him by Dr. Chalmers regarding the sanitary state of the city and the means used to discover and deal with breaches of the city by-laws, and as he bravely struggled with his difficulties the Chairman asked him if it would not be better simply to say he did not know. Asked about the by-laws of the Corporation, he said he had no time to read them, and it seems as though most of them were not worth the paper on which they were printed, for all the attention anyone pays to them. For instance, though there are nearly three hundred schools in Belfast, all subject to the by-laws regarding overcrowding, and though it is admitted that many, if not most, are far over-crowded, no record was forthcoming of anyone ever having been prosecuted for such breach of these by-laws, and this is only one instance out of many. On the fourth day, Mr. H. A. Culter, City Surveyor, formerly of Leinster and Cork, was examined, and gave evidence regarding the frequent flooding of parts of the city, and also regarding the building by-laws. He explained that the floods were caused by the rapid draining of the rainfall on the hills through the city, and estimated the cost of proper flood works to prevent such floods at from £60,000 to £100,000. The building by-laws were not at all up-to-date, he said, and were often difficult to apply to special cases. He made the significant admission that in many cases the would-be builder appealed from his decision to the Corporation or one of its Committees, and might obtain leave from them to put up some building which did not, in his opinion, conform to the by-laws. As property owners and jerry-builders are largely represented on the Corporation, it is easy to see the effect of such manœuvres! The Commission will not sit again till March 19th, their arrangement being to sit four days a week on alternate weeks. Professor Symmers will give evidence at an early date regarding the water supply, and it is expected that his predecessor in the Chair of Pathology and Bacteriology, Professor Lorrain Smith, now of Owen's College, Manchester, will also give evidence on the same subject.

CEREBRO-SPINAL MENINGITIS.—During the past week 32 new cases of cerebro-spinal meningitis have been notified in the city, and 15 deaths have occurred. The total number of cases now reaches 162, with 90 deaths.

LETTERS TO THE EDITOR.

THE QUACK MEDICINE TRADE.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—The letter from Mr. Henry Sewill in your last issue is direct and cogent, and is a pleasure to read in these days of dilettante selfishness. Probably some of your readers, however, will think with me that the remedy for the present state of things does not lie altogether in the hands of the medical profession. I very much doubt if the passage of the various Medical and Public Health Acts in this country were directly due to medical organisation, although doubtless they had a say in the matter. Surely Mr. Sewill credits statesmen and politicians with very little acumen when he says that they are "ignorant of the nature and extent of existing evils." It must surely be evident to any man of culture and enlightenment, for instance, that a quack cannot cure locomotor ataxy or elmsei, and that one medicine cannot be a specific remedy for a hundred diverse ailments, let alone the difficulty of first diagnosing the nature of the trouble. But when Mr. Sewill comes to the question of a Royal Commission as the only effectual way of informing "statesmen and politicians" as well as the general public, of the gross evils of quackery, then we are with him. Obviously and clearly it is "the only way." It would be a great service to the medical profession as well as to the public if you, sir, were to adopt this idea as a policy to be pressed to the front at all times and at all hazards. If I may be allowed to say so it requires somewhat of the powers of a Hercules to attack this hydra-headed monster, representative as it is of so many wealthy vested interests. Worst of all, the purity of the British press is daily defiled by the insertion of quack advertisements that are for the most part deliberate and patent frauds. Surely the least paternal of governments would be galvanised into action by the report of a Royal Commission. I trust, sir, as a true friend of the medical profession, you will resume your powerful advocacy of what I for one believe to be the only way of opening the door to much-needed reform.

I am, Sir, yours truly,
A COUNTRY CORONER.

Wales, March 11th, 1907.

[We have no intention of letting this matter drop. —ED. M.P. & C.]

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is rarely I am tempted to take up my pen and write to the journals, for a lifelong experience as a general practitioner hardly tends to develop the habit of literary expression. However, I am moved in the present occasion to enter my emphatic approval of Mr. Henry Sewill's proposal to demand a Royal Commission upon the subject of quackery. How else can the public get at the facts of the case? The newspapers are gagged by the quack advertiser. Can Mr. Sewill show the medical profession how to organise? Can he give us a plan of campaign, as he has furnished us with a war cry? My mite will be forthcoming, if wanted, for the war chest.

I am, Sir, yours truly,
WESSEX.

March 12th, 1907.

OBITUARY.

WILLIAM H. PEARSE, M.D.

IN recording the death of this gentleman, we do it with grief as that of an old friend. For upwards of forty years, Dr. Pearse has been a subscriber and contributor to this journal, and many valuable contributions from his pen may be found in its past volumes. He was, moreover, personally known to us as a large-hearted man, courageous in his opinions, and extremely courteous to those who differed from him. It may be said of him that he literally worshipped his profession, and anything he did or wrote of medical import was done with the sole object of throwing light on some obscure subject, or of furthering the advancement of medical science. Deceased was of commanding presence and possessed a robust constitution, having travelled extensively and occupied Government posts in Australia, the West Indies, &c. Up to a few weeks since he was apparently in the best of health, but caught a chill during the recent severe weather, gastritis supervened, and he died of exhaustion on Thursday last in the 77th year of his age. Dr. Pearse, after retiring from Government service, settled in private practice in Plymouth thirty-five years since, and enjoyed from that date until his death the ungrudging respect of his fellow townsmen, an extensive practice, and the veneration of the poor, by whom he was regarded as "the good Samaritan." Dr. Pearse was twice married, and leaves a widow, a son, and two daughters, for whom the deepest sympathy of a very wide circle is felt. The son, Dr. W. W. Pearse, holds a medical appointment under the Government at Hong-kong, and is at present at Plymouth.

WILLIAM HEATH STRANGE, M.D.ABER. M.R.C.S., L.S.A

WE regret to record the death of Dr. Heath Strange, for over fifty years one of the best known and most highly esteemed medical practitioners of Hampstead. Dr. Strange was educated at St. Thomas's Hospital and Aberdeen University, and after taking the diplomas of M.R.C.S. and L.S.A., graduated M.B. and C.N. in 1865. The next year he proceeded to the M.D.. Settling in Hampstead, he was eventually elected on the staff of the Hampstead General Hospital, and also to the Hampstead Provident Dispensary, both of which institutions he served for many years. The chief contribution to the medical literature was the article on "Diseases of the Rectum and Anus" in "Pirrie's Surgery."

ALLAN MACFADYEN, B.SC., M.D.EDIN., F.I.C.

WE regret to announce the death of Dr. Allan Macfadyen, who died on March 1st. at the age of 46. He was born in Glasgow, and was educated at the Collegiate School, Edinburgh and at Edinburgh University, and in London, also studying at Göttingen, Berne, and Munich. From 1889 till 1892 he was Sanitary Research Scholar of the Grocers' Company. He was formerly professor of bacteriology in the College of State Medicine, Great Russell Street, and afterwards bacteriologist at the Lister Institute of Preventive Medicine at Chelsea. He had been Fullerian Professor of Physiology at the Royal Institution, and was a Fellow of the Institute of Chemistry and of the Royal Medical and Chirurgical Society. Dr. Macfadyen was a contributor to the Proceedings of the Royal Society and to professional publications, and was the author of a paper on the "Chemical Action of Bacteria on Albumens and Peptones," published in the Local Government Board Reports, 1889.

HON. ALAN HERBERT, M.D.

IT is with deep regret that we announce the death of the Hon. Alan Herbert, M.D., which occurred on March 9th, at his residence in the Rue Duphot. The news of his death will come as a blow to the British colony in Paris, of which he was the doyen, and to friends in France and England, as no one could have been more universally beloved. The brother of the late Earl of Carnarvon, Alan Molyneux Herbert was educated at Harrow and at Christ Church, Oxford, and came to Paris for the purpose of studying medicine, where he took a brilliant degree. After a competitive examination he became house physician at one of the Paris hospitals in 1865, and soon afterwards he entered on the active practice of his profession. When the war broke out between France and Germany Dr. Herbert remained doing splendid service with the ambulances, and in 1871 he was appointed physician to the Hertford British Hospital, a position which he retained until a few years ago, when he retired. For the many valuable services which he had rendered during the siege of Paris and afterwards, Dr. Herbert was created a Knight of the Legion of Honour and only lately he was promoted to the rank of officier of the Order. Dr. Herbert was a little over seventy years of age, but until recently there had been every hope of his continuing in health and strength for a long time.

SPECIAL ARTICLE

THE UNIVERSITY QUESTION IN IRELAND.

THE important issue as to the form the Government proposals with regard to University Education in Ireland should take is being warmly debated and it is now known from an announcement made in Parliament that the promised legislation will not be introduced till after Easter.

Although no official report has been published of the attitude adopted by the General Assembly of the Presbyterian Church towards Mr. Bryce's proposals, it appears from a paragraph which has been going the round of the press that, while there was practical unanimity as to the amendments necessary in order to bring the proposals into harmony with the recognised non-sectarian policy of the Presbyterian Church, there was at the same time a very substantial minority of those present opposed, on academic expediency as well as on grounds of public policy, to the solution of the question by means of the establishment of one National University. The minority also considered that while Dublin University and Trinity College required large reforms it would not be in the interests of higher education in Ireland to deprive them of autonomy by merging them into a University governed and controlled by divergent and antagonistic educational ideals.

A meeting of the Catholic University School Union was held last week under the presidency of Professor E. J. McWeeney, M.D., at which the following resolutions were adopted. :—

On the motion of Sir A. Chance—

"That this meeting of the Catholic University School Union hereby welcome the declaration of the Government's intention to deal immediately with the question of University education in Ireland."

On the motion of Dr. O'Carroll—

"That no scheme for University Education in Ireland providing a College acceptable to Catholics can be satisfactory unless such College be within the University of Dublin, with endowment and autonomy on a par with those enjoyed by Trinity College."

It may be remembered that Professor McWeeney, who is a Fellow of the Royal College of Physicians, gave evidence before the late University Commission, in which he strongly criticised the attitude which he maintained was adopted by the Royal College towards Roman Catholics. This criticism naturally caused a great deal of indignation amongst the Fellows of the College, and was especially remarkable coming, as it did, at a time when the President of the College was a Roman Catholic. We understand that the College have registered a strong opinion to the effect that there was no justification for Dr. McWeeney's evidence.

A meeting has been summoned by the Provost of Trinity College, on the requisition of the Dublin University Defence Committee, which all graduates and past and present members of the College are invited to attend. It is to be held on March 22nd, in the Examination Hall of the College, and admission will be by ticket. All who propose being present are requested either to sign their names (with address) in the porter's book, or to send a postcard to the Committee so that proper arrangements can be made.

Those who are opposed to the proposals should note that the President of Queen's College, Galway, is against the scheme, not merely because his own College is omitted, but on general grounds as well.

An interesting illustration of the principle that blood is thicker than water is to be found in the fact that a largely attended meeting of graduates of the University of Cambridge was held at Caius College, Cambridge on March 2nd, to support their brethren of Trinity College, Dublin, in resisting any encroachments on their interests. Sir Robert Ball presided, and among those present were the Master of Trinity, Cambridge, the Masters of Christ's, Pembroke and Corpus, the Vice-Chancellor, Mr. S. H. Butcher, M.P., and Mr. J. F. P. Rawlinson, M.P. (the members for the University), Professors Sir George Darwin, K.C.B., Ridgeway, Howard Marsh, Bonney, Clarke, and many other distinguished men. After an eloquent speech by the chairman, Dr. Butler, Master of Trinity, moved the first resolution :—

"That we desire to protest against any legislation which would transform the University of Dublin into a University comprising colleges identified with different religious denominations and animated by conflicting educational ideals; such change must be attended by the introduction of sectarian division into the administration of the University, and must subject teaching and research to limitations injurious to liberal education and free inquiry. This protest is not made on any political grounds, but solely in the interest of liberal education."

Dr. Butler said that he begged to say that he sympathised with all his heart with every word in the resolution he had moved. If the Roman Catholic laity of Ireland desired a University in Dublin controlled by their Hierarchy, he thought English statesmen ought to grant it, and not be deterred by the Protestant feeling of England, Scotland or part of Ireland. But it was one thing to give to Roman Catholics a special form of higher education, to be conducted by their own faculty if they wished it, and a totally different thing to them when they asked for the pulling down of the large part of one of the noblest and most ancient of the institutions in Ireland.

The Master of Christ's (Dr. Piele) seconded the proposition.

Professor Joly supported the resolution and thanked the members of Cambridge University in the name of Trinity College, Dublin, for their kindness in coming there that day in their support.

The resolution was carried unanimously.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT GYNÆCOLOGICAL AND OBSTETRICAL LITERATURE.

Management of Bowel of Doubtful Vitality in Operations for Relief of Strangulated Hernia and Intestinal Obstruction.—Hall (*Amer. Jour. Obstet.*, February, 1907). There is a group of cases in hernia and obstruction operations where the surgeon is in doubt as to the vitality of the injured portion of bowel, and it is to the treatment of this uncertain condition the writer wishes to call attention. He has devised a means which has proved eminently satisfactory in a number of cases. The method consists in employing a single layer of iodoform gauze about three inches broad, placing it against one side of the mesentery and carrying it over the diseased bowel until it rests upon the mesentery of the opposite side, extending a couple of inches beyond the bowel of doubtful vitality upon each side, and placing this loop of bowel surrounded by the gauze just inside of the abdomen. The wound is dressed in the usual way, leaving the end of the gauze surrounding the bowel projecting out of the wound a foot or more. Immediately after operation the peritoneum commences the process of walling of the gauze, which fixes it by adhesive inflammation, and by the end of three or four hours it is thoroughly walled in with a layer of lymph. The perforation is not likely to occur for three or four days, or later, and by that time the gauze is thoroughly walled off, and if leakage of pus or fæces occurs, there is a ready exit for it along the strip of gauze through the open wound, and a temporary anus is established. Within a day or so after this occurs the gauze can be removed and replaced by a drainage tube.

F.

Abdominal Sinuses.—Pierce (*Amer. Jour. Obstet.*, February, 1907). Upon examining several of these discharging pockets, we find a ready means of classifying them by the character of the discharge. (1) The serous sinus, (2) the mucous sinus, (3) the true fistula. The serous sinus is essentially an unhealed abscess, tubular in form, the walls of which are lined with granulations exuding serum and kept open because of the inability of the deeper portions to cicatrize. The predisposing causes are constitutional diseases, tuberculosis, cancer, or syphilis, and among the local causes are drains of gauze or tubes, silk ligatures, calculi, clamps, needles, suture ends, &c. In the treatment a bacteriological examination of the discharge to determine if infection be present should first be done. If absent germicides are of no use, examine for foreign material, and if present, remove, and then direct attention solely to increase the reparative powers of the tissues. Mild stimulants, such as balsam of Peru, or emulsion of Aristol, or 1 in 500 solution of formaldehyde used daily, have proved successful. Mucous sinuses are not unlike the foregoing, but examination of the discharge proves it to be mucous, broken down mucous membrane, and pus. There are three organs which may furnish it—a gall bladder with occlusion of the cystic duct, an appendix with occlusion of its proximal end, and a fallopean tube occluded at or near its isthmus. There is one other source of a pseudo mucous sinus, and that is a ruptured ovarian cyst or a remaining portion of cyst wall. The prognosis in mucous sinus is bad, unless operated upon, no other form of treatment being of any avail. Fæcal fistula, considering the grave lesion and character of the organs involved, the prognosis is surprisingly good. Spontaneous healing occurs in 55 per cent. of cases, and Hirst says, "the majority of fæcal fistula close spontaneously in a few days; if not the case should be treated expectantly for nine months. If it does not close in a year it probably never will." Secondary laparotomy for closure has a mortality of 25 per cent. As soon as the leakage occurs the fistulous track should be cleaned thoroughly at frequent intervals with some antiseptic, and the canal closely packed with iodoform gauze saturated with balsam of Peru, stopping just short of the intestine. The dressing should be removed daily. When this opening has become quite small the bowels should be thoroughly cleared out by some cathartic; then the peristalses should be checked by morphia and kept at rest for one week, giving concentrated food, and then the bowels should be moved by enemeta. This procedure may have to be repeated several times.

F.

Pyelitis Complicating Pregnancy.—Meek (*Amer. Jour. of Obstet.*, February, 1907. The pyelitis to which the author refers is an acute inflammation which develops during pregnancy, and is dependent in some way on the pregnant condition for its causation, in some cases partially subsiding before completion of gestation, and where usually all signs of the inflammatory process pass off in a few weeks after delivery. The symptoms consist of history of pain in right kidney region, running down the ureter coming on rather suddenly, and accompanied with chills, fever, sweats, digestive disturbances, emaciation and urinary irritation. Examination of the urine shows it to be acid, containing pus and epithelial cells, quantity of urine is not diminished and micturition is not painful though frequent. It should be kept in mind that at the very onset of the disease no pus may be found in the urine—nothing, perhaps, but a trace of albumin and a few hyaline casts. Pus, however, soon appears. The etiology of the condition, according to Vinay, depends on two factors:—(1) compression of the ureter by the pregnant uterus; (2) infection of the urinary track above the point of compression. In all reported cases in which a bacteriological examination was made of the urine, with one or two exceptions, the infecting organism was found to be the colon bacillus. From personal experience the author agrees with Cragin, "that the interruption of pregnancy is seldom if ever necessary." The medical treatment consists of rest in the recumbent posture, fluid diet, largely of milk and large quantities of water, laxatives and saline purgatives, with urothropin in 5-grain doses largely diluted every four hours.

F.

The Influence of Disinfection of the Vagina on Puerperal Morbidity.—Since the statistics concerning antepartum douching of the vagina contradict each other, and the question is still undecided, it has been taken up again by Baisch under the supervision of Döderleim (*Archiv. fur Gyn.*, Bd. lxxix., Hft. 2). Firstly in order to exclude all other sources of infection' indiarubber gloves were always used during examination, cleansing and disinfection of the vagina and the external genitals. Secondly, in order to exclude extra-genital diseases a bacterial examination of the lochia was made in all fever cases. Thus, through recognition of the microbes, it was also possible to separate the infection on an actiological basis. In a thousand spontaneously delivered women five hundred were douched at the beginning of labour, five hundred were not. Corrosive sublimate solution 1:1000 was used. First it must be mentioned that the results showed that there was no difference whatever between those cases in which internal examination were not made at all and those in which they were made with gloves. Among the five hundred who were not douched 40 got fever (8 per cent.); among the five hundred who were douched 64 got fever (12.8 per cent.). If one divides the lying-in periods of those who got fever into disturbed, that is—a single rise of temperature over 38.5° in the rectum—and diseased, it is found that severe and moderate disturbances were about twice as frequent in those who were douched as in those who were not douched. The very important bacteriological examinations demonstrated that true streptococcal infection was present in 38 per cent. of those who were douched and in only 23 per cent. of those who were not douched. The fact, therefore, is that the corrosive douching instead of removing the cause of the puerperal sepsis favoured its settlement and propagation. Finally, the author analysed the different fever cases with regard to the problem of autoinfection, and he concludes that this occurs in only a very few cases.

G.

Cysts of the Corpora Lutea.—Grouzdew (*Archiv. fur Gyn.*, Bd. lxxix., Hft. 2) reviews the literature dealing with the serous cysts, hæmatoma of the corpus luteum, and the so-called degeneratis luteinalis polycystica. He describes three cases, and comes to the following conclusions. Cysts of the corpora lutea may attain considerable dimensions and very great practical importance. They often deviate from the original type and resemble follicular cysts. Still they keep the folding of the lutein layers. The multiple development of hæmatomata in the corpora lutea with typical lutein celled layers is a particular form of multiple degeneration. The dimensions which the hæmatoma can attain are also of great practical importance. The contents of the hæmatomata may arise from hæmorrhage from the capillaries of the lutein layer, which open directly into the cavity. In some cases the so-called epithelium which lines the interior of the cystic lutein structure is nothing else than morphologically altered endothelium of the capillaries of the lutein cell layer. One cannot regard the excessive development of lutein tissue in the ovaries as specific of hydatiamole and syncytioma. The author lays particular stress on the lining endothelium. He observed it in cylindrical cell and goblet cell form, and also as syncytium. These facts, he says, makes one think that perhaps the authors are right who look upon many tumours which are described as chorio-epitheliomata as being nothing other than endotheliomata.

G.

MEDICAL NEWS IN BRIEF.

Edinburgh Royal Asylum—Dr. Clouston's Report.

Dr. T. S. Clouston, the physician-superintendent of the Edinburgh Royal Asylum, has presented his report for 1906. The admissions during the year were 385, of whom 169 were men and 216 women. The number under treatment during the year was 1,269. The close connection of mental disease with bodily ill-health and weakness was, he said, well brought out by the fact that only thirty-five of the 385 patients admitted were in really good bodily health, and that twenty-five of them died within a month of admission. The number of cases of general paralysis—that dread and hitherto incurable disease—sent to them was fifty-five, or nine less than last year. Last year the number of women general paralytics exceeded that of the men, which was a unique and unprecedented fact for any asylum, and had not been repeated this year, for there were thirty-five men and twenty women. Even that, however, far exceeded the proportion of female to male general paralytics in any institution in Scotland. Dr. Ford Robertson, the superintendent of the Scottish Asylums Laboratory, had, with Dr. M'Rae, the pathologist of the Edinburgh Asylum, made distinct progress towards a knowledge of the true nature of this disease, its definite diagnosis, and, they thought, of its treatment, with a view to cure. Their success would be of such service to humanity as would mark an era in medical science. The great hope lay in the fact that the new treatment was on the lines of modern pathological experience, being virtually on the same principles as the mode of treatment now commonly adopted in regard to diphtheria and such diseases as were caused by specific microbes. Alcohol, continued Dr. Clouston, was, as usual, the commonest of all the outward causes of the disease in those admitted. As yet the prevention of mental disease was in its infancy. In no department of human effort to benefit humanity was the modern spirit of optimism more helpful or more needed than in the treatment of the mentally afflicted.

Extension of Lewis's Medical Library.

Mr. H. K. Lewis's well-known firm have just completed a considerable extension of their premises in Gower Street by the inclusion of 24, Gower Place, adjoining. The two shops have been made into one, the older portion being retained as the Second-Hand Department. The new shop faces Gower Street and Gower Place, and affords greater convenience to customers for inspecting the latest books in all branches of medicine, surgery and general science. The library is entered from the end of the shop, and has three windows facing Gower Place. Subscribers are able to examine the books on the shelves when making exchanges, and convenience for writing or making extracts is also provided, the idea being to make this department a reading-room for subscribers, especially those residing in the suburbs or the provinces. The telephone in this room is free for subscribers' use, so that clients from the country may arrange appointments conveniently. Lavatory accommodation is also provided for the necessary "wash and brush up" after a journey, or a prolonged inspection of books. The address will still be 136 Gower Street, and as is generally known the premises are within a minute's walk of the Metropolitan Station, whilst the new Tube station at the junction of Tottenham Court Road, Euston Road and Hampstead Road is only a few minutes distance. The termini of the Great Western, Great Central, London and North Western, Midland, Great Northern, and Great Eastern, are thus within easy access, while the new north and south Tubes, and the numerous lines of 'buses bring the South Western and Southern Districts within comfortable reach.

Important Midwifery Proposals at Bath.

The Town Clerk of Bath recently submitted certain recommendations suggested by the Midwife Committee. The proposals included the formation of a Midwife Committee, consisting of 21 members—14 being members of the Council and seven co-opted. They also suggested that they be given power to deal with all matters coming within the meaning of the Midwives Act. The Town Clerk also read a letter from Mr. H. A. Hope, hon. secretary of the District Nursing Institute, in the course of which he stated that his institution had under consideration the possibility of extending the midwifery work done by their nurses. The committee felt that the charitable public could not be called upon to support more than two nurses, and that if more nurses were to be employed the cost must be guaranteed from some other source. Having suggested that the cost of a nurse, which was from £80 to £90 a year, could be partly covered by a fee payable by the patients, the letter went on to say the committee wished to ask the Council to consider the expediency of giving a sufficient annual grant to enable them to engage a nurse to live on the south side of the river, who would undertake the midwifery work in that neighbourhood. Owing to lack of funds the institution could not now take midwifery cases for less than a fee of 10s. 6d., but if they could lower the charge they were sure it would be an immense boon to the poor patients all over Bath, and they could then obtain thoroughly skilled attendance for the same fee as they now obtain a woman who had no hospital training nor passed any examination. The health of the future generation, as well as that of the mothers, was so immensely affected by the sufficiency of midwifery work that they hoped it might be possible for the Council to consider it a legitimate expenditure. The Local Government Board had sanctioned a grant being given by the Somerset County Council of £150 to the County Nursing Association for which they undertook to train pupils in midwifery. Alderman Phillips: It is necessary that people coming into the world should have as much care bestowed upon them as those who are going out. Dr. King said it was quite right that steps should be taken to prevent the loss of infant life. He would suggest that the matter be adjourned for a fortnight to give the committee an opportunity of thinking the matter over. Dr. Paton supported the idea, and in the course of his remarks declared that such institutions did much to promote thrift and reliance among the working classes. Further consideration of the matter was accordingly adjourned for a fortnight.

Infant Life Protection.

Mr. Staveley Hill's Amending Bill for the Protection of Infants is backed by Sir John Kennaway, Mr. Arthur Lee, Mr. Hay, Mr. Walrond, Mr. Ramsay MacDonald, Mr. Hills, and Mr. Nicholls. It is an amending Bill, and must be read in conjnnction with the Act of 1897.

The Act of 1897 was tentative, and the Society for the Prevention of Cruelty to Children have always held that it did not go far enough. By its terms a person receiving for hire or reward more than one infant under five years of age for the purpose of nursing or maintaining such infants apart from their parents for longer than forty-eight hours, or receiving an infant under two years of age, to bring up in consideration of a sum of money not exceeding £20 paid down, was obliged to give notice to that effect to the local authority within forty-eight hours.

Thus, if people took in one child only at a time they were exempt from official supervision, although it is evident that such a child runs a greater risk of ill-treatment, since the wholesale adoption of children is likely to attract attention, and neighbours may exercise a surveillance. Mr. Staveley Hill proposes to extend the Act to cases where only one child is taken, and to any child received in consideration of a sum of money paid down, whatever the amount may be, and to raise to seven years the age limit of children. There are other useful provisions, too, to strengthen the law dealing with professional baby farmers.

National Hospital for Consumption—Annual Meeting.

The fifteenth annual meeting in connection with the Royal National Hospital for Consumption for Ireland, was held on March 7th, at the Royal College of Physicians, Kildare Street, Dublin, Mr. R. O'B. Furlong, C.B., Chairman of the Board of Governors, presiding. The annual report was read, and the Chairman, in proposing its adoption, said that since the opening of the hospital they would be interested to hear that 2,100 patients had passed through their hands. Last year there were 498 patients treated, or 28 more than in 1905; 402 were discharged, being 24 more than in 1905, and four died. Of those discharged, 38 were very much, 138 much, and 134 simply improved. That showed a total of 310 patients improved as compared with 277 in 1905. In 342 cases the tubercular bacillus was discovered—a percentage of 83.8, as compared with 81.4 per cent. in 1905, and 75 per cent. in 1904, which rather pointed to greater care in admission of the cases or possibly more accurate observation. The Registrar-General followed with an important speech in which he discussed the mortality rate of tuberculosis in the British Isles and in other countries. The meeting shortly after terminated.

Viceregal Commission on Poor Law.

The General Council of the Royal Academy of Medicine in Ireland have passed the following resolution on the report of the Viceregal Commission on the Poor Law:—

Resolved—That the Royal Academy of Medicine in Ireland desires to express its approval of the suggestion contained in the report of the Viceregal Poor Law Commission to convert the entire Poor Law Medical Service in Ireland into a National Service, to be paid by the State, to be entered by a competitive examination, the members of such service to be jointly controlled by the central body and the local bodies, and that the medical profession should have representation on the central body.

The Opium Traffic.

In the House of Commons on the 7th March Mr. Smeaton (Stirlingshire) asked the Prime Minister whether, seeing that crime in Burma had increased during the past twenty-five years with the growing consumption of opium, that the report just issued shows how far opium was a predisposing cause of the crimes committed by Chinese in the Transvaal, and that the opium habit was being fostered among the Kaffirs, he would take into consideration the urgency of the steady suppression of the opium traffic in and from India, which was the principal source of supply. Mr. Morley (Montrose, &c.), who replied, said:—I am not sure that crime has increased in Burma owing to the greater prevalence of the opium habit. The percentage of opium consumers to the total gaol population of Burma is less than it was in the past. The subject, my hon. friend may be certain, is receiving the closest attention of his Majesty's Government from every point of view.

Attack on a Medical Man.

At Southampton last week a man named Edward Williams was charged with attempting to murder Dr. Russell Bencraft, the medical officer of the union and a well-known Hampshire county cricket captain. When an inmate at the local workhouse Williams was brought before the doctor for examination, and he suddenly produced a heavy bludgeon, but was promptly overpowered. It was said Williams was insane, and, whilst committing him for trial at the assizes, the magistrates directed him to be placed under strict supervision.

A Portable Form of Beef Tea.

A convenient and portable form of beef-tea has been introduced by Messrs. G. Foster Clark and Co., of Maidstone, who, under the name of "Ju-Vis," are preparing gelatine tablets composed of extract of beef and certain vegetable bodies. It is only necessary to cut the tablet into four pieces and add boiling water to secure a cup of beef-tea. The preparation will doubtless become popular in the household, and especially among tourists and travellers; and the fact that each tablet which is enough for a cup, costs but one penny will doubtless ensure to the manufacturers the encouragement such enterprise merits.

Royal College of Surgeons, England.

A course of three lectures will be delivered at the above College on Monday, Wednesday and Friday of next week by Professor Cecil F. Beadles (Hunterian Professor) on "The Cerebral Arteries," illustrated by specimens, drawings, and lantern-slides. The lectures will commence at 5 o'clock each day and are free to members of the medical profession and students.

The epidemic of enteric fever in Kirkintilloch is still spreading. Hitherto the cases have been all from one street, but the infected district is enlarging, and of the cases removed yesterday three were from Freeland Place. The sanitary authorities are looking to the milk supply as the source of infection. A special meeting of the Town Council has been held, at which tne doctor laid the results of his investigations before it, and preventive measures were considered.

NOTICES TO CORRESPONDENTS, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Original Articles or Letters intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces,

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Asepsis.—It is always difficult to be sure of catgut. One of the best methods is Macewen's, which consists in keeping catgut in a mixture of chromic acid (20 per cent. solution) 1 part and glycerine 5 parts, till the required degree of hardness is obtained. This may be obtained in an hour or two, or not for four days. The gut is then washed in sterile water, dried on a sterile towel, and finally wound on glass rods, which are preserved in 20 per cent. carbolic acid in glycerine. After a fortnight the gut is ready for use.

Yeast.—There is very little known about the pathology of mucor moulds. They have been found growing in the inflammatory states of the external ear, and also post-mortem in internal organs. We should be glad to have any particulars you can furnish us with.

Dr. H. L.—There is no such appointment as you mention, but work of that kind is usually performed in the sanitary department; that is, if it is undertaken at all. It is obviously a duty that should be performed by a medical man acquainted with pathology, but an inspector often without training is generally detailed for it.

DEATH'S REHEARSAL.

'Tis sad, we every day rehearse
One act of the primeval curse.
Death sentence, passed on all.
We practically die each night,
And either wake to morning light,
Or wait the "Trumpet's Call."—A. D.

Metastasis.—If A was engaged for the confinement but could not attend, and B was called in by the friends, it would be impolitic in the extreme to charge a fee, except for the purpose of paying B. This should be made clear. The correct course would have been to have called on B at the earliest moment and thanked him for his services, as this would have given an opportunity for explanations. We may say it would be difficult to convince a jury that he had done you a wrong, as jurymen always look at things from a strictly commercial point of view. But we are not sure that B ever knew that you had been positively engaged. It is a wise plan to ask for half the fee when booking a confinement, as this gives you the opportunity of naming your own substitute should you be unable to attend.

R. H.—An excellent antiseptic mouth-wash with a not unpleasant taste is that used at the Dental Hospital, containing formaldehyde and creolin. The formula is as follows:—

℞ Creoline - - - - -	♏xv
Formaline - - - - -	ʒi
Ol. Gaultheriae- - - - - Ol. Bergamot - - - - -	} āā ♏v
Sp. Chlorof. - - - - -	ad. ℥i

Misce. A few drops to half-a-tumblerful of water.

Meetings of the Societies, Lectures, &c.

Wednesday, March 13th.

Hunterian Society (London Institution, Finsbury Circus, E.C.). 8 p.m.: Short Discussions on Diseases of Children. Short Papers:—Dr. G. Carpenter: Nephritis. Dr. D. Lees: Administration of Salicylates. Mr. H. Barnard: Intussusception.

Dermatological Society of London (11 Chandos Street, Cavendish Square, W.).—5.15 p.m.: Meeting.

Medical Society of London (Whitehall Rooms, Hotel Métropole).—7 p.m.: Anniversary Dinner.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. M. Collier: Clinique. (Surgical). 5.15 p.m.: Lecture:—Dr. G. N. Pitt: Brachial Paralyses.

North-East London Post-Graduate College (Tottenham Hospital, N.).—Cliniques:—2.30 p.m.: Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Out-patient (Dr. Whipham).

Thursday, March 14th.

Ophthalmological Society of the United Kingdom (11 Chandos Street, Cavendish Square, W.)—8 p.m.: Card Specimens. 8.30 p.m.: Papers: Dr. W. C. Rockliffe; I., Acute Septic Meningitis with Thrombosis of Cavernous Sinus; II., Sympathetic Irritation occurring after 18, 22, 28, and 50 Years. Mr. A. R. Brailey: Cysts of the Ciliary Body.

Society of Arts (John Street, Adelphi, W.C.).—4.30 p.m.: Sir James Thomson: The City of Madras.

British Gynæcological Society (20 Hanover Square, W.).—8 p.m.: Specimens will be shown by Mr. Spanton, Dr. Macnaughton-Jones, and Mr. Jessett. Paper:—Mr. S. Bishop: Mobile Kidney, with a Description of an Operation for Anterior Hepatopexy.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical). 5.15 p.m.: Lecture:—Mr. F. C. Wallis: Suppuration in Bone—Non-tuberculous.

North-East London Post-Graduate College (Tottenham Hospital, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques: Medical (Dr. Whiting), Surgical Out-patient (Mr. Carson). 3 p.m.: Medical In-patient (Dr. Chappel). 4.30 p.m.: Lecture:—Dr. G. F. Still: Some Medical Aspects of Physical and Mental Development in the Child.

Friday, March 15th.

Society for the Study of Disease in Children (11 Chandos Street, Cavendish Square, W.).—5 p.m.: Papers and Clinical Evening followed by Discussion. Patients in attendance from 4.30 p.m.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. R. Lake: Clinique. (Ear).

North-East London Post-Graduate College (Tottenham Hospital, N.).—9.30 a.m.: Clinique. Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. Leslie).

Vacancies.

Manchester, Township of.—Assistant Medical Officer. Salary £110 per annum, with furnished apartments, fire, light, washing, and attendance. Applications to James Macdonald, Clerk to the Guardians, Poor-Law Offices, New Bridge Street, Manchester.

Aberdeen University.—The McRobert Fellowship for Cancer Research.—Fellow. Salary £200 per annum. Applications to Secretary of the Medical Faculty, the University, Aberdeen.

Cornwall County Asylum, Bodmin.—Third Assistant Medical Officer. Salary £140 a year, with furnished rooms, rations, laundry, and attendance. Applications to Medical Superintendent.

Warwick County Asylum, Hatton.—Junior Medical Officer. Salary £130 per annum, with apartments, board, washing, and attendance. Applications to the Medical Superintendent.

Lewes Dispensary and Infirmary and Victoria Hospital.—Resident Medical Officer. Salary £120 per annum, with furnished apartments, board, coal, gas, washing, and attendance. Applications to the Hon. Sec.

Wandsworth Union Infirmary, St. John's Hill, near Clapham Junction.—Junior Assistant Medical Officer. Salary £100 a year, board, lodging, and washing. Applications to the Medical Superintendent.

Saint Andrew's Hospital for Mental Diseases, Northampton.—Third Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

Warneford Hospital, Leamington.—House Surgeon. Salary £100 per annum, with board, washing, and apartments. Applications to the Secretary.

Saint Pancras Parish Infirmary.—Assistant Medical Superintendent. Salary £120 per annum, with furnished apartments, rations, and washing. Applications to the Medical Superintendent.

Somerset Hospital, Capetown.—Chief Medical Officer.—Salary £450 per annum, with house. Applications to Davis and Soper, 54 St. Mary Axe, London, E.C.

Durham University, College of Medicine, Newcastle-upon-Tyne.—Head Laboratory Attendant in the Bacteriological Department. Applications to the Secretary. (See advt.).

Appointments.

Beattie, James Martin, M.D., C.M.Edin., to the Chair of Pathology in the University of Sheffield.

Clark, R. L., M.B., M.S.Edin., Certifying Surgeon under the Factory and Workshop Act for the Maryport District of the county of Cumberland.

Harrison, A. T., L.S.A., Medical Officer of Health to the Durham Rural District Council.

Lacey, Hugh Kirbell, L.R.C.P.Lond., M.R.C.S., Honorary Physician to the Rosehill Children's Hospital, Torquay.

Rushton, Charles Chapman, M.B., B.S.Lond., L.S.A., District Medical Officer and Public Vaccinator of the Macclesfield Union.

Marriages.

Foster—Beveridge.—On March 6th, at Our Lady of Lourdes Church, Uxbridge, Rowland J. Foster, R.A.M.C., second son of J. R. Foster, Esq., Greenhithe, to Phyllis Victoria, second daughter of Mr. and Mrs. Henry Beveridge, of "Rostrevor," Southall.

Deaths.

Macauley.—On March 7th, at 17 Nevern Road, London, William Robert Macauley, M.R.C.P.I., aged 64.

White.—On March 8th, at 6 Southwell Gardens, Queen's Gate, London, Helen Jane, wife of the late Joseph White, F.R.C.S.E., D.C.L.

West.—On March 8th, Charles West, L.D.S., R.C.S.Eng., of "Fernville," Fortis Green, East Finchley, N., and 41 Finsbury Square, E.C.

HARLEY STREET.—To MEDICAL MEN.—One of the best Houses in the Centre of the Medical Profession, with stabling, for Sale, having a lease of 33 years unexpired, at a very low ground rent.—For detailed particulars apply to W. Burnell Tubbs, Surveyor, 68 and 69 Shoe Lane, E.C., and 37 Barbican, E.C. Phone. 3,755 Central.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIV. WEDNESDAY, MARCH 20, 1907. No. 12

NOTES AND COMMENTS.

Boston "Culture."

DURING the last few days there has been some agitation at the stupendous results achieved in Boston by "five reputable physicians," who have been weighing people immediately before and after death. These gentlemen, under the leadership of a Dr. Duncan MacDougall, have discovered the interesting fact that the soul weighs about half an ounce, and that at death it takes longer to leave the body of a large fat man than that of a small thin one. These reputable physicians are said to be upset because their researches, like those of Koch with regard to tuberculin, have been prematurely disclosed to the public, and they fear that ridicule may be forthcoming from medical colleagues, and other carnally-minded folk. This task of soul-weighing is said to have been one of extreme difficulty, which we are quite prepared to believe, but that every allowance was made for bodily secretions, excretions, and moisture, and some commentators have already taken the results so seriously as to write articles on them, deprecating undue scepticism and arguing that it is absurd to adopt the *a priori* view that the soul is imponderable. At the risk of offending the five reputable physicians and their partisans, we beg to express the view we are sufficiently prejudiced to conclude *a priori* that such experiments do as little credit to the 'investigators'' intelligence as to their good taste. Boston is generally supposed to pride itself on its culture; we are unable to decide whether this evidence of it savours more of fatuity or ghoulishness.

Exit Dowie.

THE death of John Alexander Dowie is more a matter for pity than exultation. The wretched creature will live in the minds of men as example of how every reasonable and decent instinct in human nature may be sacrificed on the altar of self-deception and love of distinction. The character-complex of persons of the Dowie type is so far removed from the experience of the ordinary man of the world that he has only such words as impostor, liar, and humbug wherewith to describe them. These certainly are the nearest suitable terms in the language, but they do not precisely cover the ground. Dowie was not a humbug in the sense that (for example) Mr. Winkle was. Mr. Winkle was a pure humbug; he knew he could not skate, but feared to lose his character as a sportsman if he acknowledged his impotence. Dowie was a moral pervert who drew no distinction between his power to deceive himself and his power to deceive others. He suffered from grandiose hallucinations, and the admiration of his followers converted these into *idées fixes*. No doubt Dowie was as much convinced that he was Elijah as that prophet himself was of his own existence, but Dowie's influence lay in his ability to impart this preposterous notion to others.

General Paralysis.

OF course he was a heartless scoundrel, but then so are many of the inmates of Broadmoor and other prisons and lunatic asylums; but his swindling of the sick was not of the cold-blooded type of Professor Richard. Everything that consorted with his own depraved mind was merely a means of exalting his conceit, and the pitiable ease with which he found dupes doubtless intoxicated him with ideas of his power and splendour. No doubt among the lists of cures were to be found many cases of real faith-healing of a more or less permanent character, and, indeed, such healing powers are really not to be marvelled at in a man who could fleece money out of his followers to the prodigious extent that he did. For many years Dowie must have been in the incipient stages of the malady which has just closed his miserable existence, and his whole career is bitter sarcasm on the common-sense of the quack-ridden American race. Medical men can only shrug their shoulders and wonder what is in store for a country which allowed such a pernicious lunatic to swindle and dupe its citizens for so long. Australia and, happily, London, would have none of him.

Anti-vivisectionists and Honesty.

A propos of some remarks we made last week on the falsehoods by which the antivivisection cause is kept going, we have received a letter from Miss Kidd, Secretary to the British Union for the Abolition of Vivisection, which will be found in our correspondence columns. In it we are said to appear to feel no scruples when attacking antivivisectionists. We should like to point out that we were not attacking but defending. An absolutely false accusation had been made against the medical profession, and though it had been categorically refuted, no apology, so far as we could make out, had been made in the journals in which the accusation was made. Conduct of that character we have become accustomed to in the antivivisection movement—reckless assertion and absence of shame on exposure. Miss Kidd says that a little consideration will, she hopes, induce us to withdraw the remark "the honest man has no place in any of the antivivisectionist organisations of our time." By that we did not mean that there are no honest men in the antivivisection movement; there are, and that is where the danger lies. What we meant was that such should withdraw themselves from the leadership of the protagonists, and if they were convinced of the moral wrong of experiments on animals, seek by moral methods to make their convictions known.

Humanitarianism and Discretion.

There are people who say that they would rather their children should die than purchase life at the price of animal experiment, just as there are people who say they would rather their children had small-pox than were vaccinated. Such a position is conceivable even if not comprehensible on ordinary rational and humanitarian grounds, and people who occupy it have the right of all free citizens to make their views known so long as they do so fairly and straightforwardly. But when there are a number of societies of similar aim competing for public favour, such as the four antivivisection societies, it is not wonderful that each should trip over the other in its desire to dish up horrors and pillory experimenters. There is, we believe, a Society for the Abolition of Capital Punishment, which advocates the abrogation of the extreme penalty of the law. That society, so far as we know, is content to pursue its object by unostentatious moral suasion. We do not read lurid letters sent to the papers from its officers every time a prisoner is sentenced to death, accusing judges of nameless barbarity, gaolers of foul glee, or executioners of blood-lust. On the contrary, these officials are treated with respect and regarded as the agents for the expression of the will of the community. Their duties are such as the public can understand, and calumny would be generally resented. The scientific experimenter must, from the nature of his work, be more or less "caviare to the general," and false statements and insinuations about him and his motives are far less easily exposed to public reprobation. There is no body of men more humanely disposed than the medical profession, and none who would resent cruelty to man or animal more keenly. Those who honestly wish to protect animals from hardship would do well to be guided by its expert advice.

Health Visiting and Medical Treatment.

The creation of a new office, such as that of a female health-visitor, is certain to be surrounded with unforeseen difficulties, as we have already said in this column. Not the least of these is the possible clashing of her work with that of medical practitioners. We are all the more pleased, after what we have said, to notice this point is safeguarded in a code of instructions for duty to a female health visitor, whom it was decided to appoint at Beckenham last week. The Council passed these instructions, drawn up by a small committee of which one member was a medical man, with general approval, and they are likely to be most helpful to the officer and to all connected with her work. But the chief point that we are concerned with is that in all cases of absence from school on account of illness, it is specifically stated and printed in italics that she is to offer her services *under the directions of the medical man in attendance*. That is as it should be, but we are considerably less satisfied with another instruction, namely, that where "in her opinion any case seen at school would be benefited by her services at the child's home, she is to attend at the home and offer her services or advice to the parents *under the direction of a medical man, if one is in attendance*." This gives the health visitor even greater latitude than the midwife, for the latter, at least, is under statutory obligation to advise that a medical man should be sent for in certain eventualities. In our opinion, in the interest of the Beckenham children, the clause ought to be considerably modified. No health visitor should undertake medical treatment of any kind except under the supervision of a qualified doctor.

LEADING ARTICLE.

THE BITTER CRY OF THE NOSTRUM VENDOR.

There is a pretty proverb which asserts with terse emphasis the advantages accruing to honest men when rogues fall out. From the medical point of view, all persons who claim to cure manifold or incurable diseases by means of a single specific are rogues. It follows, therefore, that our readers are likely to be interested in the occurrence of a quarrel among the patent medicine vendors that is assuming the dimensions of a pitched battle. The war cry is "Substitution," a term that may, of course, be used by honourable firms who find out that other wares are being palmed off on intending customers instead of their own legitimate products, which receive the sanction of the medical journals and are often largely used by the medical profession. The substitution to which we allude, however, is another and a totally different matter. It is the substitution of one rogue's particular roguery in place of another. To take a concrete instance, A, although untrained in medical matters, conceives that he has discovered a cure for cancer, and proceeds to advertise his "Anticancrum Fluid," which, by dint of the application of keen business methods, attains a large sale. B, wishing to purchase some of A's famous specific, goes to a vendor of patent medicines and asks for a bottle of the "Anticancrum Fluid," for which he is prepared to pay the exorbitant sum fixed by its proprietor. Then the substitution begins. In the most suave manner the seller excuses himself for not having the desired article in stock, but he recommends another potion, that of C, "Cancerdeletor, K88," which is "far better in every way," which not only alleviates but cures the malady in question, "gets at the roots of it," so to speak, and is used by many of the crowned heads of Europe. In this hypothetical case, it is clear that the misdirected enterprise of A is shorn of its profits by the equally misdirected and more circuitous roguery of C. It is the old, old story of the—

"Big fleas have little fleas upon their backs
to bite 'em,
These fleas have other fleas, and so *ad infinitum*."

Let us for a moment examine B's position in the matter. He is simply the credulous victim, duped by A and C, who buys the worthless stuff and pays the penalty of deluded hopes, often with unutterable pain and anguish, and of the lost opportunity of early surgical interference. If he can be snared into the belief that an uneducated farm labourer can find a cure for cancer where scientific medicine has hitherto failed, it is plain that B's judgment is defective and that his information as to the disease itself and the results of orthodox medical treatment must be inaccurate and incomplete, to say nothing of the impossibility of his controlling the statements of the quack. Yet B comes from all ranks of Society, from duke to chimney-sweep. It is common for a testimonial to come from Lord this or Lady that, saying that Smith's elixir or Brown's panacea has cured locomotor ataxy, or epilepsy, or cancer, and the writer wishes the world to be informed of the great boon that is thereby conferred upon humanity. Clergymen and dignitaries of the Church are notoriously given to write puffing testimonials for nostrums, thereby proving what everyone knows already, that a mind that may be accurate enough in a special limited province of work may be hopelessly at fault in the elementary principles of reasoning in outside matters. In a certain limited sense we submit that the amateur cancer curer, be he university professor or farm labourer, is, for all practical purposes, an ignorant and dangerous quack, from whom B should be protected by any modern State anxious to protect her subjects. For if B cannot protect himself against the snares of the fowler, it is the duty of the State to intervene in his behalf. That is the inevitable position in any properly constituted scheme of Government. Apparently nobody knows and nobody cares what is put into the nostrum. The newspapers and the proprietors reap a golden harvest, while the credulous public and the incredulous medical practitioners pay the piper. The extent of the evil can only be guessed at, but its proportions probably exceed the wildest estimate that can be formed by the average man in the street. To gain the data for a more accurate knowledge of the extent of the patent medicine trade and its attendant evils a Royal Commission of enquiry is urgently needed. In our opinion it is worthy of being placed in the forefront of medical politics as an object of first importance. Not only would a Royal Commission secure a basis of accurate fact, but it would serve to educate the public as to the incalculable evils wrought upon the community by quacks and quackery. Meanwhile it is not a little amusing to hear the bitter cry of the successful charlatan at finding his wares ousted by those of a later quack. The sale is effected under the excuse that the one is "just as good" as the other; but, as a correspondent has kindly pointed out, this is clearly the reverse of what should have been expressed for a very short acquaintance with the composition of quack remedies would convince the most sceptical that one is just as bad as another, while the majority are absolutely unfitted for the routine purpose for which they are sold.

CURRENT TOPICS.

Another Imposition.

ONE of the great problems of civilisation is to secure equal justice to the rich and poor. Although it is a common boast that all classes are equal in the sight of the law, in practice this is far from being the case. A fine of forty shillings may mean a month's imprisonment for a labouring man, though to a well-to-do one it does not even mean the deprivation of one cigar. In the same way, when a rich man sustains wrong or injury he has no difficulty in setting all the legal machinery of the land in motion, whilst his poor brother has to grin and bear it. It is a real hardship that the poor who sustain injury are dependent on the mercy of the speculative solicitor, and it is more than a hardship, it is a gross injustice, that medical witnesses in such cases should be kept hanging about courts to the detriment of their practice and patients if expert evidence is required. Some proper provision, with adequate safeguards, should be made to meet such cases. Last week, the father of a child who had been bitten by a dog brought an action against the owner, and a medical man was subpœnaed to give evidence on his behalf. The medical man in question objected to be sworn till his fee had been paid, and after an unedifying plea *ad misericordiam* had been made by counsel for the plaintiff, the doctor adhered to his decision. Of course, counsel did not lose such an opportunity for sarcasm at the expense of medical charity, nor for gaining sympathy for his client; but the real point was untouched. There was no real gravity about the case, but the plaintiff had cause for action, and ultimately recovered forty shillings damages. In any properly organised legal system, it should have been possible to obtain medical aid at a proper remuneration.

Starch in Cream.

IN his last monthly report Dr. Collingridge, the energetic medical officer of health for the City of London, drew attention to the pernicious custom of adding starch to cream. There is, he says, no legal definition of cream, the fat present in any sample depending upon various factors and varying from 15 to 55 per cent. The public naturally form their opinion of the value of cream by the only standard available to them—*i.e.*, by the thickness. The addition of starch or gelatine gives a fictitious appearance of thickness, which bears no relation to the actual amount of fat present. A departmental committee as far back as 1901 reported "that the artificial thickening of cream by any addition of gelatine or other substance shall raise a presumption that the cream is not genuine," and Section 6 of the Sale of Food and Drugs Act, 1875, makes it an offence to sell any article of food to which any matter or ingredient not injurious to health has been added fraudulently to increase the bulk, weight, or measure, or "to conceal the inferior quality thereof." Now that attention has been drawn to the point there will be no excuse in future for sanitary authorities in various parts of the Kingdom if they do not take precautions to ensure the purity of the cream supplied to the public within their jurisdiction.

Trypsin and Cancer.

PROTEST was made by the reputable medical journals when, some months ago, the trypsin treatment of cancer became the subject of sensational articles in lay papers. The evidence on which Dr. Saleeby and others relied for their extravagant statements was easily seen to be insufficient, and in the light of further information has vanished altogether. Dr. Bainbridge, of New York, has published in a contemporary a full and evidently careful account of the case described by Dr. Morton as "a most remarkable atrophy of an entire cancerous breast," the same case which furnished Dr. Saleeby with the basis for his excited gospel to the public in the pages of the *Pall Mall Gazette*. As a matter of fact, the breast in question, undoubtedly affected with carcinoma, had been treated not only by injections of trypsin, but by repeated exposure to X-rays. When examined by competent pathologists the tumour was found to show in its central parts degeneration of the cancer cells with increase of connective tissue, and toward the surface increase of both tumour cells and stroma. Peripherally, however, the tumour showed columns of tumour cells in good condition, extending into the lymph spaces. In other words, as one of the pathologists says, the tumour had "the typical appearance of scirrhous carcinoma." The "conquest of cancer" will have to be substantiated by more solid evidence than is supplied by this one less than dubious case.

Mr. Haffkine and the Indian Government.

A LONG letter from the vigorous pen of Professor Ronald Ross appeared in *The Times* of March 15th on the subject of Mr. Haffkine and his treatment by the Indian Government, and we fancy it will be heartily endorsed by medical feeling throughout the country. Professor Ross points out that Mr. Haffkine went to India in the darkest days of its sanitary administration, when, in spite of the light that sanitary science was shedding on social problems in every civilised country, India remained sunk in the depths of that stereotyped officialism which knows of nothing but seniority and pension. The inroads of scientific teaching were, he says, scoffed at and opposed by officialism of that type, and Mr. Haffkine's anti-cholera vaccine was coolly received. In 1896, however, cholera gave way to plague, and in Bombay, through want of proper care on the part of the authorities, got so vast a hold that nothing could stop it. Mr. Haffkine, by his bacteriological knowledge and ingenuity, elaborated his anti-plague prophylactic, which Professor Ross thinks has saved more lives than any discovery save Jenner's. Everyone knows about the Mulkowal incident; how the persons, nineteen in number, who were inoculated from a particular bottle of a consignment of prophylactic, died of tetanus. A Commission which inquired into the matter came to the conclusion that the contamination of the bottle was due to a mistake in Mr. Haffkine's laboratory, whereas it now seems the contamination occurred after the bottle was opened, and that Mr. Haffkine's directions as to its use were not followed. At any rate, it seems that on the Commission's report Mr. Haffkine was deprived of his position, and beyond his salary while in India, and the doubtful compliment of a C.I.E., he has nothing to show for half a lifetime of scientific work and discoveries of the greatest value in the saving of human life. Even if the contamination occurred in the laboratory—which is denied as impossible—Mr. Haffkine was only technically and not personally responsible, and without him there would have been no prophylactic at all. As Professor Ross says: "Unless the verdict is amended, such men will hesitate before going to a country where the most meritorious service seems only to lead to neglect and censure."

Dakhyl v. Labouchere.

THE judgment of the Lord Chancellor and the other judges of the House of Lords in the above case last week will come as a great relief to medical men and writers generally. The unanimous judgment of the Court was that the Court of Appeal was right and that the Lord Chief Justice, who tried the original action, was wrong, and that the verdict and damages of £1,000 for libel obtained by Dr. H. N. Dakhyl against Mr. Labouchere must be set aside, and a new trial undertaken. There was clear misdirection on two vital points by the Lord Chief Justice, and it is astonishing how that able man could have gone so far astray. The first was the definition of a "quack," which he only allowed to be interpreted as a "pretender to skill which the pretender did not possess." As the Lord Chancellor pointed out, the word has a much wider meaning, and could with propriety be used of a person, however skilled, who lent himself to a medical imposture. The second point was that the Lord Chief Justice told the jury that there could be no fair comment, which was pleaded by Mr. Labouchere, without justification. This point was set aside by the House of Lords, and quite reasonably. Comment may be fair and designed in the public interest, although through mistake, inadvertence, or minor slip it is not wholly justified. The point is precisely one for a jury. We congratulate Mr. Labouchere on obtaining these important decisions.

Devonshire C.C. and Midwives.

The Devonshire County Council is one of those health authorities which finds itself so gifted by nature with medical knowledge and sanitary acumen that it needs the advice of no mere medical officer of health in the execution of its duties. But though the laws of epidemiology and disease-prevention are to them as an open book, they found themselves somewhat non-plussed at having to take over the supervision of midwives in the very wide area that they govern, and after delegating their powers to the local district councils and finding the arrangement for some reason does not work, they have now taken the unusual step of handing over the inspection to the poor-law medical officers of the various areas. Now, although the poor-law medical officers are undoubtedly capable of inspecting the midwives, bags and dresses, the arrangement seems so much at variance with the practice of other counties that we cannot help wondering if there is not some deeper signification than meets the eye. If it be merely an attempt to evade the awkward question of payment of fees to medical men called in by midwives by directing the attention of midwives to the poor-law medical officers, and hoping that the latter will not claim fees for attendance on labours because of the honorariums they receive for inspections, it strikes us as unfortunate. The matter of these fees must be settled definitely, and that soon, and no compromise can be acceptable or accepted.

Mr. Stead and the Evans Brothers.

The latest phase of quack doctoring and religiosity is that exhibited by the ministrations of the Brothers Evans. These persons are small Cardiganshire farmers of a low standard of education, who have conceived the idea that they are endowed with certain healing powers from on High, and who are treating with extraordinary success (of course) cases of cancer which pour into their "surgery" from all parts of the country. Mr. Stead, with his usual want of co-ordination between sail and ballast, has been investigating *au grand sirieux* this crude manifestation of ecstatic credulity, and is convinced that there is a *prima facie* case for experiment. He is much hurt that the Cancer Research Committee refuse to take any notice of the Evans' methods, because the great brethren will not divulge the "secret" of their preparations, but in order to put the method of healing so unreasonably disregarded by the Committee at the disposal of sufferers, he is undertaking to send patients down to Cardigan on certain conditions. Well, there is no reason except those of common-sense and common humanity why they should not be sent, and there is no doubt that they will be described as wonderfully improved after a week or two, and as little doubt that as they get worse less and less will be heard from them. It has all been done before' under varying sets of circumstances, so frequently that it is extraordinary that even Mr. Stead can be "had." By-the-by, it is significant to notice that that enterprising journalist seems to have given up Julia and her fellow spirits, and now uses hard words about "psychic researchers."

PERSONAL.

Dr. J. H. H. Harrison has been appointed Colonial Surgeon of British Honduras in succession to Dr. C. H. Eyles, with effect from September 1st last.

Dr. A. C. McLean has succeeded the late Dr. J. S. Gibbons as District Surgeon of Prieska, Cape Colony.

Dr. J. C. Budding, an official of the German Government, who is staying in London for the purpose of studying the methods and organisation of the Metropolitan Police, paid a visit to Bow Street Police Court.

The Mayor of Chester on March 13th presided over a meeting at the Town Hall, Chester, convened for the purpose of publicly recognising the services of Dr. James Taylor on his retirement after forty years' service as surgeon to Chester Infirmary.

The Public Health Committee of Edinburgh Town Council on March 12th agreed to recommend that Dr. Cullen, Convener of the Committee, and Dr. Robertson, be sent as delegates to the Congress of the Royal Institute of Public Health, which is to be held in Douglas, Isle of Man.

The Committee of the Dundee Dispensary has decided that the following short list should be presented to the Council:—Dr. Kerr, Dr. Smith, and Dr. Thornton.

Owing to the illness of Lord Selby, the Royal Commission on Vivisection has decided to adjourn until after Easter.

Mr. Noel A. Humphreys, I.S.O., read an important paper before the Royal Statistical Society last night on "The Alleged Increase in Insanity."

The Lord Mayor takes the chair at a meeting at the Mansion House this afternoon to promote the interests of the Second International Congress on School Hygiene, to be held in London next August.

Mr. Edwin T. Hall, R.I.B.A., will read a paper on "Sanatoria," at the general meeting of the Architectural Association on March 22nd.

Professor G. Sims Woodhead has been appointed Representative of the University on the Council of the Lister Institute in place of the late Sir Michael Foster.

Mr. J. Ernest Lane, F.R.C.S., Surgeon to St. Mary's Hospital, has been elected a member of the Court of Examiners, Royal College of Surgeons, England.

Mr. Rickman J. Godlee, Surgeon-in-Ordinary to H.M. the King, Holme Professor of Clinical Surgery, University College, has been appointed Bradshaw Lecturer for 1907 in the Royal College of Surgeons, England.

A CLINICAL LECTURE
ON
DIABETES. (*a*)

By T. K. MONRO., M.A., M.D., F.F.P.S.G.,

Physician to the Glasgow Royal Infirmary and Professor of Medicine in St. Mungo's College.

The Flaw in Diabetes.—In diabetes there is a flaw in the method by which the organism deals with carbohydrates, just as in gout there is a flaw in the method by which it deals with nitrogenous materials, and accordingly diabetes has been termed the "gout of the carbohydrate-eater." Both diseases may show a very marked family tendency. In the case of gout this fact is so notorious as to need no illustration, while with regard to diabetes I may mention that I had recently under my care a boy who recovered for a time, but afterwards relapsed, and who was the fifth child in one family of twelve to perish from that disease. The defect in gout is in the excretion of nitrogenous waste matter, while in diabetes it is in the assimilation of carbohydrates.

Carbohydrate Assimilation.—The principal carbohydrates are divisible into three groups :—

I. Polysaccharides (amyloses), having the formula $(C_6H_{10}O_5)n$, and including starch, glycogen, dextrin, cellulose, and gums.

II. Disaccharides, having the formula $C_{12}H_{22}O_{11}$ and including saccharose (sucrose, cane sugar), lactose (milk sugar), and maltose (malt sugar).

III. Monosaccharides (glucoses) having the formula $(C_6H_{10}O_5)$ and including dextrose (glucose, grape sugar), lævulose (fruit sugar) and galactose.

Now the evidence goes to show that it is only the monosaccharides that can be directly utilised by the body. It is not enough that the carbohydrates should be rendered soluble and thus made capable of absorption by osmosis. The disaccharides and polysaccharides must apparently be hydrolysed or hydrated by the addition of one or more molecules of water before they can become attached to or incorporated in the protoplasmic molecules of the living body. For instance, the polysaccharide starch is hydrolysed by the diastatic enzymes of the saliva and pancreatic juice, through various intermediate stages into the disaccharide maltose. But it appears to be subsequently hydrolysed into the monosaccharide glucose by an enzyme which is found in the intestinal mucous membrane.

Of the disaccharides, again, saccharose or cane sugar, though highly soluble, is yet not suitable for use by the living protoplasm. It is accordingly hydrolysed under the influence of invertase, a ferment which is present in the small intestine, and according to Pavy in the stomach also. The result is the production of invert sugar, which is a mixture of the two monosaccharides, dextrose and lævulose. Similarly lactose, which is a disaccharide, is hydrolysed under the influence of lactase, an enzyme found in the mucosa of the small bowel, and yields the two monosaccharides, dextrose and galactose. So that among the functions of the alimentary tract is the production of enzymes for hydrolysing or hydrating a number of the carbohydrates into the monosaccharide form. Accordingly, when an individual takes saccharose (cane sugar) to such excess as to render the urine saccharine, the sugar that is excreted is glucose ; and when a diabetic patient takes either saccharose or lactose, it is glucose which appears in the urine in consequence. If saccharose is injected into the blood-stream directly, it is of no use to the organism and simply passes out in the urine. Pavy finds, however, that the disaccharides lactose and maltose are not wholly wasted when introduced into the body in this way, and that the monosaccharides, and particularly dextrose, are retained for the purposes of the organism to an even greater degree.

The Fate of Glucose.—Glucose, then, being the end-product of the digestion of carbohydrates, we come now to the question of absorption and distribution, a subject which has given rise to great controversy in the past.

(1) According to the glycogenic theory, which in its original form is due to Claude Bernard, and which in some form or other is still held by a good many authorities, the glucose is conveyed by the portal vein to the liver, where by a process of dehydration it is converted into the polysaccharide glycogen or animal starch $(C_6H_{10}O_5)$. It is further held that after being stored in the liver it is re-converted into glucose and discharged into the blood to be conveyed to the tissues as the latter may require it. In diabetes, therefore, the increase of sugar in the blood may be due to increased production of sugar by the liver, or to inability of the liver to convert the sugar into glycogen.

(2) Pavy, on the other hand, maintains that under normal conditions two lines of defence exist to prevent the carbohydrates from getting into the blood in any quantity. These are the intestinal villi in the first place, and the liver in the second place. He considers that the lymphocytes in the lymphatic tissue of the villi feed upon the glucose (as they probably do also upon the peptone), and as they multiply, proceed through the lacteals to the circulation, giving rise to part at least of the digestion-lymphocytosis which is so well known to follow a meal. Another portion of the starchy food is devoured by the columnar epithelium which covers the villi, and is converted into fat. Any glucose which escapes these two agencies in the first line of defence passes by the portal vein to the liver, where it is converted into either glycogen or fat. Pavy further suggests that when the time comes for this glycogen to be utilised, it is reconverted into sugar, and almost at the same instant taken on as a side-chain by a proteid constituent of the blood, just as oxygen is transported to the tissues linked to hæmoglobin. In support of these views he has brought forward evidence which goes to show that proteid matter is of the nature of a glucoside, a body which, though possessing none of the properties of a carbohydrate, can yet be disintegrated by an acid or an alkali so as to yield a carbohydrate.

One of the most important points in Pavy's teaching is that the glucose derived from the food does not pass through the circulation towards the tissues in the free state, since if it did—and according to the glycogenic doctrine, it does—glycosuria would necessarily result. He goes so far as to say that when sugar reaches the circulation, it shows itself in the urine in a corresponding proportion, so that the urine becomes a quantitative indicator of the sugar-content of the blood. Other observers, however (V. Noorden, Seegen, Naunyn), have not always been able to recognise such a constant relationship between the sugar-content of the blood and that of the urine in diabetes.

It would seem that though the glycogenic theory has still influential adherents, a good deal of the evidence on which Bernard founded it must now be set aside as unreliable. Not only has Pavy been the propounder and powerful advocate of an alternative hypothesis, but he quotes Lépine, a staunch supporter of the glycogenic doctrine, as having recently reported certain

---

(*a*) Delivered at the Glasgow Royal Infirmary on Feb. 12th, 1907.

results of a comparison between arterial and venous blood which are utterly opposed to that doctrine. Then, again, V. Noorden, who admits that the sugar in the blood is probably in a loose combination with some other substance, and who at the same time believes that diabetic glycosuria is due to the inability of the liver and muscles to transform into glycogen the sugar which reaches them by the blood, calls attention to the fact that Bernard and others, working with obsolete and inexact methods, estimated the sugar-content of normal blood as 2, 3, or 4 parts per thousand, whereas it barely exceeds 1 part per thousand in man.

Hyperglycæmia.—To pass on now from the region of keen controversy, it may be taken as generally recognised that, apart from one exceptional condition, glycosuria is a result of hyperglycæmia. The exceptional condition is phloridzin diabetes. Phloridzin is a substance which is found in the bark of the cherry tree, and which when introduced into the animal body, whether by the stomach or in any other way, tends strongly to induce glycosuria. In this instance the sugar is apparently formed in the kidneys themselves, probably, as suggested by Pavy and others, by the disintegration of a proteid constituent of the blood. The very slight increase which may be present in the sugar content of the blood is attributable to absorption from the kidneys. In other kinds of diabetes, the sugar of the blood often amounts to 3 or 4 parts, and occasionally to as much as 10 parts per thousand, while the normal is somewhere about 1 per thousand.

Unfortunately, the withdrawal of carbohydrates from the food of the diabetic is not always followed by cessation of the glycosuria. Under these circumstances sugar is formed from proteid matter—probably both from food proteids and from tissue proteids. How this occurs we can partly understand if we bear in mind the glucoside structure of the proteid molecule as already described; but why it should occur is a difficult question which I shall not discuss at present.

Tests for Sugar in the Urine.—For the detection of sugar in the urine numerous tests are available. Some of these, such as Fehling's, Trommer's and the Bismuth test, depend upon the fact that certain metallic salts are reduced on being heated in alkaline solution with saccharine urine. The fermentation test is reliable, though not very delicate. The liquor potassæ and picric acid tests, and the polariscope, need simply be mentioned here. The phenyl-hydrazin test of Emil Fischer, who by its means has been enabled to prepare many new sugars, depends on the fact that the different sugars form characteristic crystals with phenyl-hydrazin, a substance which is prepared from anilin. These crystals consist of osazones which can be distinguished from one another by their form and by their melting point. The osazone obtained from diabetic urine is glucosazone, which occurs in sheaves of bright yellow needle-like crystals. On the whole, Fehling's solution is the most convenient for regular use, and is a reliable guide for clinical purposes. 10 c.c. are reduced by 0.05 gramme glucose. Pavy's ammoniated cupric test is much more delicate, and may be used to demonstrate the interesting fact that a certain amount of sugar is invariably present in normal urine; 10 c.c. of Pavy's solution are reduced by 0.005 gramme glucose.

The Acetone Bodies.—Examination of the urine in many severe cases of diabetes reveals the presence of the acetone series of bodies, viz., β-oxybutyric acid and its two derivatives, acetone and diacetic acid. It has long been generally supposed that these bodies are derived from proteid disintegration, though in recent years it has been considered by some investigators that they are mostly derived from fatty acids. Assuming that they are derived from proteid, we may regard them as by-products in the formation of sugar from that source, and accordingly by testing for the acetone bodies, we may ascertain whether the sugar in the urine is derived solely from carbohydrates, or in part from proteid also. Diacetic acid is recognised by the port-wine colour given to the urine by the addition of perchloride of iron, care being taken to avoid fallacies due to the presence of drugs such as salicyli acid. Acetone is recognised by the fact that when sodium nitro-prusside and caustic soda are added to the urine, a cherry-red colour appears, which on the addition of acetic acid in excess gives place to a carmine red. β-oxybutyric acid can be detected by its lævo-rotatory influence on completely fermented urine, and by the difference between the results obtained when the sugar-content of the urine is estimated by the polarimeter and by Fehling's solution.

Limits of Carbohydrate Assimilating Power.—The essential feature, then, of diabetes is the great diminution in the carbohydrate-assimilating power of the body. But it is to be noted that even in health this power is not unlimited, and there is no doubt that it varies a good deal in normal individuals. It is true that in the case of starch there is no known limit, but this is probably on account of the relative slowness of the process by which it is hydrolysed and absorbed. According to Von Noorden, the limit for glucose and also for cane sugar is 150 to 200 grammes in one dose; for lævulose 140 to 160 grammes; and for milk sugar 120 grammes or less. Hutchison, however, puts the limit for lævulose at 200 grammes. There is reason to believe that individuals with a low assimilation limit are "potential diabetics," *i.e.*, are more liable than normal persons to become the subjects of diabetes mellitus.

Etiology of Diabetes.—The etiology of diabetes, notwithstanding all that has been said and done, remains a mystery. Hereditary and family tendencies, the male sex, the Jewish race, affluent circumstances, the early degenerative period of life, a neurotic temperament, city life, hard brain-work, anxiety, sedentary habits, obesity, gout, excesses in food and drink; malaria, syphilis and other infections; mental shock, with or without injury to the head, abdomen, or some other part of the body; lesions of the nervous system, and disease of the pancreas—all these deserve to be mentioned in a list of possible causes. The rare marital form, in which husband and wife both suffer, may possibly, as in the case of marital tabes, be a late result of syphilis acquired by the husband. The connexion between diabetes and the islands of Langerhans or the ductless gland portion of the pancreas is not yet fully explained; but the hypothesis is a reasonable one that the gland produces an activator or co-ferment which constitutes one element in a double enzyme. The other element, according to Otto Cohnheim, is present in the muscles, and there, he supposes, the carbohydrates are burnt up. Pavy, on the other hand, suggests that the activator supplied by the pancreas is wanted to enable the bioplasm of the intestinal tract to build up the absorbed sugar into the proteid molecule.

Hurtful Effects of Glycosuria.—Persistent glycosuria is hurtful to the organism in at least three primary ways. In the first place, the glycosuria means a waste of so much food, with the correspondingly increased demand on the activity of the digestive organs to compensate for this loss. In the second place, the deposition of sugar on the genitals may give rise to troublesome local symptoms. In the third place, and worst of all, the hyperglycæmia constitutes a toxic state of the blood, which, if it persists for a long time, tends to bring about grave consequences in the tissues: the lungs, the crystalline lens, the skin, the nerves, the spinal cord.

Degrees of Diabetes.—In the alimentary type of diabetes, the glucose of the urine is derived simply from the carbohydrates of the food. But in progressive cases the diabetes tends to become composite, the sugar being then derived from the disintegration of proteids as well as from carbohydrate food. And there is some reason to believe that the constant bathing of the tissues with the excess of sugar, in cases of the alimentary type which are not properly treated, favours the transformation of the disease into the more dangerous composite variety. When this happens there is an additional quantity of energy wasted from the body, since both the sugar, and the acetone bodies derived from the disintegration of the proteid tissues, are eliminated in the urine before being fully oxidised, and therefore before yielding up all the energy they contain.

Acidosis.—A danger of a yet more formidable kind threatens the patient when the acetone bodies are liberated into the system in large quantity. This is due not so much to their poisonous properties, for it is doubtful if they are poisons in the ordinary sense of the word, as to their acid character, whereby they combine with the alkali of the blood and interfere with the latter in the discharge of one of its most important functions. For just as the hæmoglobin of the red corpuscles combines with the oxygen inspired into the lungs, and conveys it from the lungs to the tissues, so in health the alkali of the blood combines with the carbon dioxide produced in the tissues and conveys it from the tissues to the lungs to be expired. But when a condition of acidosis develops, and the alkali of the blood is in great measure appropriated by β-oxybutyric and other acids, the carbon dioxide will accumulate in the tissues, and thus the "air-hunger," which is such a striking phenomenon of diabetic coma, is readily accounted for.

Symptoms of Diabetes.—We need not at present linger over the familiar symptoms of diabetes: the polyuria, the hunger and thirst, the loss of flesh and strength, the dry skin, and the red tongue. The urine is acid and pale, the daily output, in a case of moderate severity, being from 5 to 15 pints, the specific gravity from 1032 to 1045, the proportion of sugar from 8 to 12 per cent., and the sugar output from 15 to 25 ounces. Mild cases, however, are often met with; and, moreover, febrile and other intercurrent illnesses may cause a temporary diminution or arrest of the glycosuria.

Coma.—The most important complication of diabetes is coma, which supervenes in about half the cases, and is almost invariably fatal. Its onset is frequently rapid and occasionally actually sudden. Among the influences which appear to promote its development are muscular fatigue, obstinate constipation, high acidity of the urine, early life, and perhaps a sudden withdrawal of all carbohydrates from the food. The most characteristic form of diabetic coma is the result of acidosis, as already explained; and among its phenomena there is not only air-hunger, but also a sweet odour of the breath and urine, which is due to the presence of acetone. In a few cases the approach of coma is heralded by the signs of collapse, while in others there are headache and disordered gait without air-hunger. In occasional instances the coma is uræmic in its origin.

Phthisis.—Pulmonary tuberculosis, a complication of diabetes which is the cause of death in about a third of the cases, deserves particular mention because pyrexia, cough and other symptoms may be slight or absent, though the changes in the lungs are making rapid progress. There are various other complications which are well known and need not be alluded to now.

Prognosis of Diabetes.—Of all the elements which go together to make up the prognosis, age is the most important. If the patient has passed the prime of life, the tendency is for the disease to be chronic and dietetic, whereas in childhood and early adult life it is pretty sure to become composite sooner or later. Many of the cases in middle life are of considerable severity; and though capable of undergoing improvement under treatment, are likely to prove incurable. Patients of the hospital class are naturally apt to suffer after they escape from strict supervision from the danger attending the use of unsuitable food. Apart from the age of the patient, our principal guide in prognosis is the condition of the urine as regards the absence or presence of the acetone bodies, and the disappearance or non-disappearance of sugar when a carbohydrate-free diet is enforced. Most of the severe cases of diabetes terminate in coma. The slighter forms of the disease tend to bring about death in other ways, viz., by diminishing the powers of resistance against such infections as tuberculosis, pneumonia and influenza; and by favouring the premature development of senility in the arteries, with such consequences as gangrene of the lower limbs, and apoplexy.

Treatment.—In approaching the treatment of diabetes it is manifestly the most important thing to withdraw the carbohydrates from the food, since these are not only wasted by being excreted in the urine, but positively harmful by inducing a toxic state of the blood. It is perhaps putting the same thing in another way to say that when the carbohydrate-assimilating mechanism is disabled, the first indication is to give it a complete rest, just as in neurasthenia we give the nervous system a rest. It is a good practice, when the patient comes under observation, to keep him for a couple of days on ordinary diet (except that sugar is replaced by saccharin), so as to allow of the sugar output being ascertained. Thereafter, the ordinary diet should be replaced by one from which carbohydrates are strictly excluded. If, to begin with, the urine does not give the reactions for the acetone-bodies, the change may be made quite abruptly, although it is perhaps as well to allow two or three days for the transition. But if diaceturia already exists, or if the disease is of old standing, it is necessary to use caution, since a very little disturbance of the general condition may suffice to precipitate the onset of coma. In mild cases the effect of the carbohydrate-free diet is to cause the disappearance of the glycosuria. If it is found after a few days that the urine remains free from sugar, a small quantity of carbohydrate, say a potato or two, or half a slice of ordinary white bread, should be added to the daily fare. As long as the urine continues sugar-free, the starchy food should be very cautiously increased, but whenever the glycosuria reappears, part of the starch should be withdrawn. Having thus ascertained quantitatively the carbohydrate-assimilating power, one should continue to give starchy food within this limit, so as to keep the urine permanently free from sugar, while at the same time giving as much carbohydrate as possible. Under these circumstances, one may look, in a certain proportion of cases, for some, and even for a considerable return of assimilating power, though this may not be for months, or even for more than a year. According to Pavy, we may infer that some such return has taken place if, while the urine is constantly maintained free from sugar, the patient begins to lose weight and experience malaise or a sense of exhaustion without any other change in his condition to account for such symptoms; whereas, so long as he continues to gain weight under a carbohydrate-free diet, we may assume that there is no such return. But as soon as signs of the return appear, carbohydrates should be begun in a cautious way.

In many cases, unfortunately, the exclusion of carbohydrates from the food, though reducing the sugar output very greatly, is insufficient to abolish it. If the glycosuria does not continue to decline, drugs may be tried, and although none can be regarded as satisfactory, one medicine may be found to be of some little service in one case and another in another case. On the whole, opium, morphine, or codeine may be looked upon with most favour, and after these perhaps arsenic and the salicylates. In all cases alkaline drinks may be given freely, and in severe examples of the disease sodium bicarbonate should be given in considerable quantity as long as the urine is acid. Constipation, fatigue and similar unfavourable influences must be guarded against as favouring the development of coma.

I may be permitted to make a few additional remarks on the subject of the acetone-bodies in diabetes.

Whether these are mainly derived from proteids or from fatty acids, their appearance in such large quantities as occur in diabetes is associated, for some reason not yet understood, with the cessation of carbohydrate metabolism in the body. Accordingly, a healthy man, who, under ordinary dietetic conditions, does not excrete more than a mere trace of acetone, will, if he excludes all carbohydrates from his food, excrete a greatly increased amount. But if he perseveres with this special diet the excess of acetone will gradually diminish to its normal insignificant proportions. In the same way, a fasting individual, who is living on the proteids and fat of his own body, manifests acetonuria. According to Von Noorden, the daily consumption of from 80 to 100 grammes of carbohydrate is sufficient to prevent acetonuria. Now, when we withdraw carbohydrates from the food of patients suffering from the slighter forms of diabetes with little or no acetonuria, the acetone-bodies are very likely to appear in the urine; and since diabetic coma depends upon the acetone-bodies, it might be thought that this result of a strict diet would involve increased danger to the patient. But apparently this is not the case, and it may suffice to reassure you when I mention that two such authorities as Pavy and Von Noorden are at one on this question. In cases of this class, if the strict diet is persevered with, the acetonuria often subsides within a few weeks, just as it does in a healthy man. If no such subsidence takes place, the outlook is not promising, whether the glycosuria is slight or severe. In the severe type of diabetes where the excretion of the acetone-bodies is well marked on an ordinary diet, it will probably be found that the presence or absence of carbohydrate from the diet makes very little difference to the degree of acetonuria. These patients are always in a precarious position, but even with them it is most desirable, and especially if they can be kept under close observation, to begin with several weeks of a carbohydrate-free diet. To diminish the risk attaching to this, large quantities of alkali should be given, and it may be well to restrict the allowance of butcher's meat. After a time a small quantity of carbohydrate may be allowed on most days, but not on all, and it may be found on trial that one particular kind of carbohydrate can be assimilated to an appreciable degree while others cannot. It is then, our duty to let the patient take advantage of the assimilative capacity which he possesses, whether that power relates to the oatmeal gruel recommended by Von Noorden, the potatoes recommended by Mossé, or some other variety of carbohydrate food. As part of this procedure, the allowance of meat should be reduced to a minimum. By methods such as these we must do our best to conduct the patient along the narrow path between the dangers associated on the one hand with a persistent hyperglycæmia and on the other with an overwhelming acidosis. Even under conditions so unpromising, very good health is sometimes maintained for a considerable number of years.

If coma threatens, a carbohydrate diet should be given and large quantities of alkali should be administered to render the urine neutral or alkaline. When this formidable complication actually develops, an alkali should be injected into a vein. Naunyn recommends 35 to 40 grammes of sodium carbonate (not bicarbonate) in 1 litre of water (9 to 10 drachms in 1¾ pints). If intravenous infusion is impracticable, 3 or 4 ounces of the carbonate should be given daily in solution by the mouth or rectum.

In conclusion, I would strongly urge you to be careful about the diabetic bread which the patient uses. The trustworthy manufacturers are very few, and bread is sold for diabetics which is simply loaded with starch. If, therefore, you are not quite certain about the manufacturer, you should apply the iodine test to every fresh variety of bread, and every specimen of bread from a new manufacturer, to make sure that it is sufficiently free from starch, before you pass it as suitable for the diabetic patient.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for this week will be by Major Ronald Ross, C.B., DSc. Dub., F.R.C.S. Eng., F.R.S., Professor of Tropical Medicine in the University of Liverpool, on "Points of Interest connected with Tropical Sanitation."*

ORIGINAL PAPERS.

TWO CASES OF SYPHILIS SIMULATING TYPHOID FEVER.

By J. D. ROLLESTON, M.A., M.D.Oxon.,

Assistant Medical Officer at the Grove Fever Hospital of the Metropolitan Asylums Board.

The possibility of syphilis being mistaken for typhoid fever has long been recognised. Fournier, in 1873, emphasised the similarity of the two diseases, and introduced the neologism "typhose" to designate the condition met with in certain cases of syphilis, particularly in women, which closely simulates typhoid fever. Illustrative cases have since been recorded by Hirschberg and Raïchline, Balzer, Moutard Martin, and Dieulafoy, in France; by Prentiss, Futcher, and McKenna in America; and by Burney Yeo in this country. The condition, however, is not a common one. Since 1896, out of a total of 3,076 cases admitted to the Metropolitan Asylums Board hospitals wrongly certified to be suffering from typhoid fever, only ten were subsequently diagnosed to have syphilis only. It is not improbable, however, that these figures are too low, and that a certain number of cases that were certified as typhoid fever and diagnosed after admission to hospital as febricula, of which there have been 136 cases since 1896, or even as influenza, of which there have been 186 cases, were in reality cases of syphilis. French syphilologists also testify to the rarity of syphilitic typhosis. Thus Carrière, of Lille, had seen only two cases in ten years; Brocq, of Paris, had seen only five cases in eight years at the Hopital Broca (female lock hospital); while Thibierge had not met with a single case in two years' experience at the same hospital. My chief object in recording the following two cases is to emphasise the importance of bearing in mind the possibility of syphilis in dealing with obscure cases of fever. The patient, especially if a woman, will often deny or be unaware of the existence of syphilis. To anyone who had syphilis in mind the evidence in these two cases was so obvious that it is probable that the existence of that disease did not occur to the certifying doctor.

It must be noted that some of the recorded cases resemble typhoid fever more closely than those described below. The spleen may be enlarged, as in the cases of Duflocq, Moutard Martin, Futcher, and Dieulafoy. The abdomen was distended in the cases of Dieulafoy and Hirschberg and Raïchline. The stools may be loose, as in the cases of Moutard Martin, Duflocq, Hirschberg, and Raïchline.

Further, it is important to realise that fever in syphilis may exist apart from any other specific manifestations, such as iritis, adenopathy, periostitis, arthritis, or skin lesions of any kind. To this variety Fournier has given the name "essential syphilitic fever," to distinguish it from the symptomatic fever which is associated with obvious syphilitic lesions. In the former case the disease may be mistaken for tubercle, as in the cases of Swediaur, Duffin, Stengel, and Janeway; for malaria (Bassereau, S. Phillips, Prentiss, Bassett-Smith, Futcher); or for influenza (Campbell Williams). Of course, typhoid fever and syphilis may co-exist. A fatal case was reported in 1885 by Davies. Etienne has published five cases in which typhoid developed in the course of active syphilis. All ran a severe course. A case illustrating the co-existence of hereditary syphilis with enteric fever I have myself recorded elsewhere.

Other febrile intercurrent diseases, such as tubercle or gonorrhœa, must be excluded before the pyrexia can be attributed to syphilis.

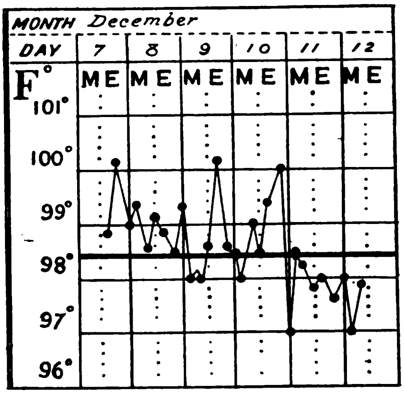
Typhoid can be excluded by a persistently negative Widal's reaction. The effect of mercury and potassium iodide will also be of great service in diagnosis.

Case i.—A man, æt. 35, a butcher by trade, was admitted at 4.20 p.m. on December 7th, 1905, certified to have enteric fever. His wife gave the following history: Three weeks ago he had had a sore throat, which the doctor regarded as diphtheria. Severe headache, which soon became intolerable, developed, and he became delirious. He was, therefore, considered to be suffering from brain disease. It is noteworthy that he had some business worries at the time. His wife had recently had a child, which died at birth, and she had herself suffered from severe headache soon after delivery. Finally, the existence of pyrexia, without anything to account for it, caused him to be certified as suffering from enteric fever. On admission, a discrete eruption of copper-coloured macules, papules, and scales was seen on the trunk and limbs. A healing chancre was found on the ventral surface of the penis at the corono-preputial junction. There was well-marked inguinal adenopathy. The epitrochlear and occipital glands were also distinctly enlarged. The spleen could not be felt, but the liver extended two fingers' breadth below the costal margin. The tongue was covered with thick white fur, and the mouth was full of stringy mucus. The speech was very indistinct, and the mind was clouded, answers to the simplest questions being obtained with difficulty or not at all. Bilateral ptosis, most marked on the left side, was present, the knee and ankle jerks were very active. The plantar reflex was flexor. The abdominal reflex was active. The patient was at once given a mixture containing Liq. Hydrarg. Perchlor. ʒi, and Pot. Iod. gr. x. 4 hourly. Shortly after admission to the ward he became very violent, requiring the constant presence of a porter to control him. The first part of the night he was very violent and noisy, but after two doses of paraldehyde he slept fairly well. The next morning he was very restless and tried to get out of bed. He was constantly picking at the bedclothes, and passed his urine under him. At 5.30 p.m. he became so violent that an injection of morphia was given and a second porter was called in. Widal's test and the diazo and methylene blue reactions were all negative.

December 9th.—The restlessness continued till 3.30 a.m., when another injection of morphia was given, after which he slept till about 8 a.m. During the day the incontinence of urine persisted, and a normal stool was passed in the bed. The ptosis was less marked. The pupils reacted to light. It was impossible to test accommodation.

December 10th.—An injection of morphia being ineffectual, three doses of potassium bromide and chloral were given in the night, after each of which he slept for a short time. While awake, he was still very violent.

December 11th.—The syphilitic eruption was fading and the ptosis was less. There were occasional lucid intervals.

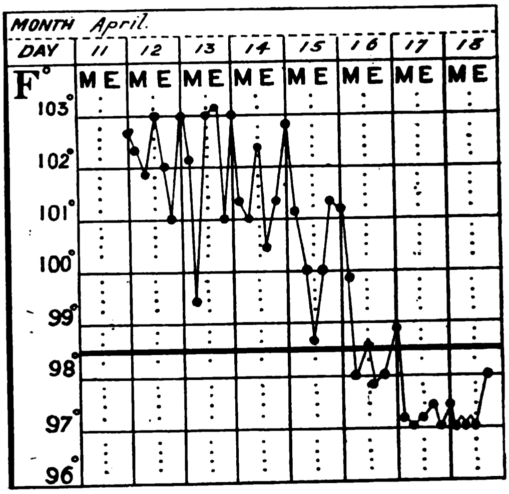


On December 12th he was transferred to Wandsworth Infirmary, where, as Dr. Neal, the medical superintendent, has kindly informed me, he died on January 2nd, 1906, his death being certified as due to cerebral syphilis.

The present case presents several interesting features. (1) The tendency that syphilis has to imitate other diseases. The mimicry is exemplified by the fact that this patient was regarded successively to be suffering from three distinct diseases before he was admitted to hospital. (2) The early implication of the brain by syphilis. Business worries acted, doubtless, as a determining cause. (3) The galloping character of the disease, and the failure of specific treatment find a striking parallel in cases of toxæmic diphtheria, which, though treated from an early stage with large doses of antitoxin, run a rapidly fatal course. (4) The annexed chart shows that the fever was of a low grade and of an intermittent type, in striking contrast to the temperature curve presented by the second patient.

(5) Of special interest in this case is the enlargement of the liver. Carrière says that the liver is always voluminous in syphilitic typhosis. This is not correct, for in some of the recorded cases it is definitely stated that the liver was not enlarged. It is noteworthy, however, that the fever in late syphilis has been attributed by some authorities, such as Crofton and Birt, to the damage done by syphilis to the liver, which is thus prevented from acting as a filter and consequently allows the passage of fever-producing toxines into the general circulation. The irregular fever may also be explained, as Gerhardt and H. D. Rolleston suggest, by secondary infection of the gummata in the liver by pyogenic organisms which have gained access either by the bile passages or the blood. In the cases of Bristowe, Cayley, and Atkinson, an hepatic abscess was suspected, and aspiration was performed. No pus was found. Yet another explanation of the pyrexia of syphilis has recently been advanced by Westphalen. According to him, the pyrexia is due neither to the absorption of necrotic material nor to the special viscus affected, but to the natural reaction against the spirochæta pallida or its toxines. This theory is supported by the fact that the spirochæte has been found in the late as well as in the early lesions, so that, as Westphalen says, the division of syphilis into different stages is rather artificial than biological.

CASE 2.—A girl, æt. 19, was admitted to hospital at 11 p.m. on April 11th, 1906, certified to be suffering from typhoid fever. She had had a headache since the 5th. On the 7th some spots had been seen on the legs. No further history was given. On admission, the patient presented the dazed condition characteristic of enteric fever. The resemblance was heightened by the sordes on the teeth, and the thickly-coated and tremulous tongue. The temperature was 102.6°. Examination of the abdomen, however, did not yield any confirmatory evidence of enteric fever. There was no distension. The spleen was not enlarged. The abdominal reflex was active both above and below the umbilicus. A few faint papules were seen on the abdomen, but they were not of the size or shape of rose spots. There was a dusky red papular eruption on the lower part of the back, the buttocks, and the lower limbs. The upper limbs were less affected. By



daylight on the 12th a generalised roseola could be plainly seen. Mucous tubercles were present in the mouth. The fauces were slightly infected. There was much inflammation of the labia minora and a purulent vaginal discharge. The inguinal glands were hard and discrete. Two grains of mercury and chalk three times in the day were ordered and a vaginal douche of 1-500 chinosol was given morning and evening. The mucous tubercles rapidly disappeared, and by the 17th the roseola had faded, leaving pigmentation. The slight degree of mental obnubilation present on admission gradually passed away. The first three nights the patient was restless, but subsequently she slept well.

The urine, which was free from albumin, presented negative diazo and methylene blue reactions. Widal's test, performed on the 14th, was also negative.

Beyond some tingling of the fingers and a slight attack of phlebitis of the lower part of the right internal saphenous vein, nothing further of note occurred, and the patient was discharged on May 1st.

I am indebted to Dr. J. E. Beggs, Medical Superintendent of the Grove Fever Hospital, for permission to publish these cases.

Spotted Fever in Stepney.

THE fourth case of spotted fever in Stepney in three weeks was reported on March 14th. The first three have proved fatal. Two cases are reported from Dingle, County Kerry, of which one proved fatal; and a fatal case has occurred at Little Dorby, five miles from Carlisle.

The Belfast medical officer of health reports four cases and one death, bringing the total death-roll to ninety-eight. This brings the total number of fatalities from this disease in that town to 102.

CLINICAL OBSERVATIONS AND EXPERIENCES;

PROGNOSIS AND TREATMENT OF LOBAR PNEUMONIA. (a)

BY JAMES O. AFFLECK, M.D.EDIN., F.R.C.P.,
Consulting Physician, Edinburgh Royal Infirmary; President of the Edinburgh Medico-Chirurgical Society.

AT the outset the author observed that if a body of physicians were asked what disease most taxed their resources and excited their interest, the majority would reply, "acute pneumonia." For this reason, because of the great practical importance to private practitioners as well as hospital physicians of the disease in question, he ventured to bring forward a paper based wholly on his personal impressions, gained during more than thirty years' experience of the disease. Two preliminary points were first to be considered:—(1) Is pneumonia on the increase? and (2) has pneumonia assumed a more serious character of recent years? It was very difficult to get an accurate reply to the first of these questions, but both the Registrar-General's statistics and American statistics point to the fact that the disease was more frequent now than formerly. In regard to the second point he was strongly of opinion that since influenza had become a visitant of this country many more bad cases of pneumonia were met with than formerly. Taking the mortality from various diseases in Glasgow, Edinburgh and the whole of Scotland, it was seen that in the influenza years 1891, 1895, 1897 and 1900 the deaths from pneumonia were greatly above the average. In the U.S. figures the mortality from pneumonia in 1880 was 83.3 per 1,000 deaths, in 1890 90 per 1,000, and in 1900 100.3 per 1,000. In the earlier years of his practice pneumonia was a satisfactory disease to treat, because so many patients did well; now these favourable cases were less common, and every case of pneumonia gave ground for more or less anxiety.

General Points in Prognosis.—There was no means of foretelling how a case might end. It was a very treacherous disease, and at any moment might deviate from the normal course and assume a threatening aspect. Age was a very important factor. Aged people comparatively seldom recovered from acute pneumonia, and this quite irrespective of the previous health. The habits of the patient, particularly in regard to alcohol, had a very important bearing on the prospect of recovery. Alcoholism outweighed the advantage of youth and vigour, and precipitated a fatal result. By far the greater number of alcoholic pneumonias died. The risk was also considerably enhanced by previous or existing chronic disease; in the insane pneumonia was always a very serious malady. Occasionally pneumonia followed a surgical operation and though grave was not always fatal. The speaker instanced the worst case of appendicitis he had ever seen, who developed pneumonia a few days after operation and yet made a good recovery.

Prognostic Indications derived from the Incidence of the Attack.—In some cases the patient is overwhelmed by the toxæmia from the first and dies, marked treatment having no chance. Cases which exhibit gastric and abdominal symptoms at the outset, and simulate some visceral lesion, are often severe. Sometimes the abdominal pain and vomiting are associated with unilateral rigidity of the abdominal muscles, and when this is right-sided the case may be mistaken for appendicitis. Cases with copious perspiration but high temperature are also to be looked on as serious. The diagnosis may be obscured at the outset by severe pleuritic pain, and also by nervous symptoms; in the alcoholic by delirium tremens, in children by a convulsion. In cases of delirium tremens an examination of the upper lobe should always be made, as pneumonia was apt to begin there in these cases.

(a) Read at a meeting of the Edinburgh Medico-Chirurgical Society held March 6th, 1907.

Prognostic Indications during the Course of the Disease.—A very important prognostic element was furnished by the amount of sleep; persistent insomnia was due to toxæmia, and was difficult to control by drugs; it was a very evil sign. Delirium, whether with or without an alcoholic history, was also a danger signal. The temperature was not a reliable guide, but in a favourable case there was often a tendency for it to fall after the fourth or fifth day, and cases in which it remained high, or inclined to rise, were anxious ones. The main determining factor in the prognosis was the state of the heart. The poison of pneumonia affected the left ventricle as well as the right; and it also profoundly disturbed the vaso-motor centres. The pulse rate was very important. If it went over 120 the case was serious, if over 130 anxious, and if over 140 the prospect of recovery was small. Any sudden change in the frequency of the pulse was also a matter of serious import. In old people the rate of the pulse is less important than the quality. A moderate amount of expectoration was better than none, and on the whole a rusty sputum was more favourable than a bloody one; prune juice spit, of course, was bad, but he had known cases recover in which there was every reason to suppose a limited gangrene of the lung had taken place. Cessation of expectoration with progressive cyanosis was very ominous. Double pneumonia was a very grave affair, and complete consolidation of one lung hardly less so.

Prognostic Indications at the Critical Period.—In a favourable crisis the most striking thing was the aspect of relief which the patient presented: at a glance it could be told that he was doing well. The features of the crisis were a fall in temperature, pulse and respirations, with a sweat; if one or other of these was absent, particularly if the temperature fell without a diminution in the frequency of pulse, it was a bad sign. Among the risks at the crisis the chief was collapse. Sometimes the crisis was delayed beyond the usual period, and these cases always gave ground for anxiety. Complications such as pericarditis or empyema might occur. In regard to treatment, it should be remembered that the physician had little power to arrest this self-limited disease. They hoped for a curative serum, but as yet none had been discovered. Three things to be avoided were over-medication, over-stimulation, and over-feeding. It was a great mistake to frequently pour quantities of milk into the patient's stomach, and so embarrass still further the respiration. He tended now to use much less alcohol in treating pneumonia than in the earlier years of his practice. The opinion was gaining ground that it had little beneficial action on the heart, and he now never prescribed it in more than moderate doses. He rather inclined to the use of strychnine early in the malady with the object of sustaining and fortifying the heart's action. Attempts at depletion in the early stage of the disease were inadvisable. For the most part the physician's duty was limited to guiding the case and dealing with symptoms as they arose. For pain he found an ice-bag to the side very useful; some patients, however, could not tolerate it, and on them light warm poultices might be held. He cautioned his hearers against the use of very hot poultices or stupes. Unless there was much pain from pleurisy nothing more than a wadding pneumonia jacket was needed. For cough he gave ammonium carbonate and chloride, but sometimes these were badly borne. When dyspnœa was a prominent feature he found spirit of chloroform and spirit of ether the best remedy. Dyspnœa might arise either from the side of the lungs, of the heart, or from poisoning of the nerve centres, so that the same remedy was not equally applicable in all cases. For insomnia his favourite drug was paraldehyde; next to that chloral with digitalis, and then, though a long way after, sulphonal trional or veronal. Opium should only be used in the early stage and with great caution; never when there was any tendency to cyanosis. The pyrexia required no treatment except sponging. Antipyretic drugs, even quinine, should be avoided. Strychnine and digitalis were the best heart tonics. Digitalis should not be repeated at too short intervals. He had tried oxygen frequently, but had been on the whole disappointed with it. One should always bear in mind that there is danger in meddling too much in pneumonia.

CLINICAL RECORDS.

SOME INTERESTING CLINICAL CASES.

By D. T. BARRY, M.D., D.P.H.

THE following three cases taken from my note-book of cases are somewhat interesting:—

A PECULIAR BULLET WOUND.

CASE 1.—J. R., æt. 22, a shoemaker, was in his shop one afternoon when a friend called. The object of the friend's visit was to order a leather case to be made for a revolver which he carried. Producing the latter, which was loaded in all six chambers, the friend playfully presented it at the shoemaker. The unexpected happened, and "ping" went the trigger.

Being the nearest medical man, I was immediately summoned, and was on the scene within ten minutes of the occurrence. Two policemen were supporting the wounded youth on a chair, one holding a handkerchief to his jaw. On examining this latter, I found a small wound at the angle on the right side, with a tiny splinter of bone just visible. I was at a loss to find where the bullet had got to, till, after a long search, I found it in the subcutaneous tissue over the left acromio-clavicular joint. From here it was easily extracted aseptically.

The splinter of bone at the angle of the jaw was removed, and the patient put to bed. No anæsthetic was given.

A careful search revealed no evidence of a subcutaneous track for the bullet either on the front or back of the neck. There was absolute inability to swallow for three days, and dysphagia for three or four days longer. Hence the bullet must have either pierced the superior constrictor of the pharynx near its origin from the mylohyoid ridge, or passed across by the retropharyngeal space, perhaps glancing off the body of the third or fourth cervical vertebra. The latter course is the more likely, as there was no trace of blood in the mouth or pharynx, and no sign of a wound of the mucous membrane.

The patient was fed per rectum for one week, and made an excellent recovery. It is unnecessary to give in detail the wealth of important anatomical structures which evaded the malign influence of this bullet. Suffice it to mention that it must have been on friendly terms with four cartoids and two jugulars, not to mention vagi and sympathetics.

A RARE COMBINATION OF OLD AND RECENT BRAIN LESIONS.

CASE 2.—W. B., a cabman, had a dispute with one of his confrères which resulted in a fight. B. got a straight blow on the jaw which upset his equilibrium and brought his occiput into violent contact with the kerbstone. He was dazed for some minutes, but did not lose consciousness, and was taken home in his cab.

Some six hours after the injury I was called to see him. He sat on a couch in the kitchen and told me that he felt quite well except for a headache. His temperature was 100 deg. F. There was a small clean-cut wound over the left occipital protruberance. This extended to the bone, which was denuded of pericranium. Probing this wound carefully, I could detect no sign of fracture. He was put to bed and given a purge, and the wound was dressed.

Next morning I was informed that he had died in the night in a convulsion

A post-mortem examination revealed a tough blood clot one inch in diameter immediately beneath the wound, and situated between the dura mater and the bone.

The extraordinary feature of the case was that practically the whole of the right frontal lobe of the cerebrum was disintegrated, and was represented by about two drams of semi-fluid grumous material, as well as by a soft dark blood clot. The dura mater had collapsed in front of the fronto-parietal suture, the parietal and occipital lobes behind the fissure of Rolando being intact. This was evidently softening from embolism or syphilitic arteritis.

At the inquest I stated that death was due to the posterior clot which was caused by the fall. Counsel for the assailant suggested that death was caused by the old-standing disease. But this I denied, while admitting that it may have predisposed to it.

This man had been a heavy drinker, and all his viscera showed signs of this. His intelligence was not below the average for his class, and he was a regular worker. The exact extent of lesion in the ascending frontal convolution could not be ascertained, but it had certainly fallen in, and was softer.

AN ABDOMINAL PUZZLE.

CASE 3.—Mrs. X., a widow of some years' standing, summoned me in great haste, as she was suffering intense pain. I found her seated in an armchair and holding her hands to her right side in the hepatic region. There was no other symptom or sign except this acute pain of sudden onset. The abdomen was somewhat rigid, and there was no region of distinct tenderness, but the pain was referred to the gall-bladder region.

I was at a loss for a diagnosis. A ¼ gr. morphia was given hypodermically, and the patient put to bed.

Later in the evening, on calling, I found the patient somewhat relieved. The temperature was now 101 deg. F. The pain was referred to the right iliac region, where a certain indefinite fulness was felt. There was a history of normal menstruation, and a P.V. examination revealed nothing unusual. I now suspected the case to be appendicitis.

Next day the patient was free from pain, and there was no rise of temperature, but the vague fulness was still to be felt in the iliac region. She continued thus for five or six days with occasional slight rise of temperature, but feeling quite well.

At the end of this period I was sent for very urgently, and found the patient now almost collapsed and in great distress, with a marked bulging of the lower part of the abdomen and a good deal of pain.

A consultant surgeon whom I called in thought it must have been a rupture of an appendix abscess. An operation was at once undertaken, when, on opening the peritoneal cavity, the blood-clots which were presented revealed the true nature of the case. It was an unusual type of ectopic gestation.

After removal of the fœtus, the hæmorrhage being very alarming, the sac was packed with gauze and the wound left open. The patient recovered.

Evidently a partial rupture of the sac first took place, and, combined with the other circumstances of the case, led to confusion. While at first ectopic gestation occurred to me, it was soon set aside by the normal history of menstruation, the absence of evidence per vaginam, the rapid amelioration of symptoms, and last, though perhaps not least, was the patient's widowhood and high social position.

THE OUT-PATIENTS' ROOM.

KING'S COLLEGE HOSPITAL.

Man brought in Comatose.

By G. LENTHAL CHEATLE, C.B., F.R.C.S.

AMONG the out-patients was a man, æt. 62, who was brought in comatose. He had a recently inflicted wound on the back of his head. The previous history of the case was as follows :—A fortnight before he had had a slight attack of giddiness which rapidly passed off. The report of his doctor was that his heart, lungs and urine had been normal. The history of the present condition was : The patient was seen writing at his desk and performing his usual daily duties, but an hour afterwards he was discovered lying on the floor with a wound at the back of his head. His state when brought to hospital was — he was unconscious and could not be roused, his breathing was stertorous, his pulse was full, 90 per minute ; the surface of the body was warm, his temperature 100° ; his pupils were equal and reacted to light ; there was no facial paralysis ; his arms were rather rigidly held flexed across his chest, his legs were rigidly extended ; his great toe was flexed towards the plantar surface during the plantar reflexes. The wound on his head, although it had bled a good deal, was superficial and did not extend as far as the bone. There was no smell of alcohol, or signs of any volatile poison. His urine contained sugar. He was evidently suffering from compression. The condition of his arteries was very good for a man of his age. There was no sign of fracture of the base, no subcutaneous effusion of blood at the back of the neck, no hæmorrhage from the nose or ears. A lumbar puncture was made for the examination of the condition of the cerebro-spinal fluid ; half a test-tube of the fluid was taken away. When allowed to settle half of it appeared to be blood containing normal red blood corpuscles ; the upper layer of the fluid was coloured by hæmoglobin. Mr. CHEATLE said the evidence deduced from the condition of the cerebro-spinal fluid had a great influence on the diagnosis of the case ; it reduced it to three contingencies : either it was a fracture of the base, meningeal hæmorrhage, or cerebral hæmorrhage. There were no supporting signs of fracture of the base. There was no history of an interval of consciousness after injury to his head, indicating a meningeal hæmorrhage, and therefore on the whole the case seemed to be one of cerebral hæmorrhage. The sugar in the urine was probably the result of the present trouble. With regard to treatment, there being a complete absence of any focal localising signs, surgical interference was contra-indicated. The withdrawal of the cerebro-spinal fluid had had no effect on the symptoms of compression. The hæmorrhage was evidently very extensive and occupied both sides ; there was no unilateral sign or symptom indicating an affection of one side only. The patient was admitted to the hospital and died after four days. The post-mortem revealed extensive hæmorrhage into the ventricles of the brain ; there was no fracture of the base. The main point about the case, Mr. Cheatle said, was the inestimable value of examination of the cerebro-spina fluid obtained by the simple harmless procedure of a lumbar puncture. In every case of coma it is wise, he thought, to make a routine practice of examining the cerebro-spinal fluid obtained by means of a lumbar puncture.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

Cholecystostomy.—Mr. Willmott Evans operated on a man, æt. 63, who had been admitted for jaundice, which had lasted several months. At no time had the patient complained of any pain in the abdomen; the jaundice had come on slowly, he had the usual symptoms accompanying icterus: colourless stools, flatulence and irritation of the skin. The urine was loaded with bile pigment Although he had not been weighed within recent years he felt sure that he had wasted. On examination, the only additional sign elicited was the presence on the right half of the abdomen, two inches below the rib margin, of an oval swelling in which doubtful fluctuation could be obtained. The swelling seemed to measure an inch and a half in length and about an inch transversely. It was rounded. Inasmuch as this swelling was in the situation of the gall bladder, and indeed appeared definitely to be the result of dilatation of that viscus, it was decided to explore. The patient having been anæsthetised, an incision was made about two inches in length in the right semi-lunar line, the upper extremity being about one inch below the margin of the ribs. The abdominal wall having been divided, layer by layer, the peritoneum was reached, and when this had been cut through the distended gall bladder presented in the wound. It was drawn forwards, packed round with gauze, and incised; some slightly thickened bile escaped, and, the finger having been introduced within the gall bladder, it was found that a large amount of stones were present; many of these were taken away with a scoop and others still were evacuated when the cavity was washed out with fluid from an irrigator. In all more than one hundred and fifty were removed. The cystic duct was free, but just below the origin of the common duct a firm resistant mass was felt, which was adherent to the neighbouring structures and surrounding the duct. As this mass seemed definitely to be malignant in nature Mr. Evans decided that it would be unwise to attempt its removal. The edges of the gall were therefore stitched to the margins of the wound, a drain was inserted and a dressing applied. Mr. Evans said that in this case the distension of the gall bladder and the profound jaundice pointed to an obstruction of the ductus communis choledocus; the two most common causes of this condition were the impaction of a stone and the constriction of the duct by malignant disease. To diagnose between these two conditions before operation was extremely difficult. The only points on which a diagnosis could be based were the following: if the age of the patient exceeded 50 years, and if the wasting were extreme, it was not improbable that the cause of the obstruction was a new growth, and the likelihood of this would be increased if at no time there had been any history of biliary colic. On the other hand, it must not be forgotten that gall stones were very frequently found in malignant disease, that in many cases they preceded the development of a malignant growth and in all probability they were directly implicated in the production of the carcinomatous mass. It was not many years, he said, since Courvoisier had formulated a law generally called by his name, that when the common duct is blocked and jaundice is produced the gall bladder is generally distended if the cause of the obstruction is a new growth, while if the blocking of the common duct is due to a stone the gall bladder will probably be contracted. Of course this law, Mr. Evans remarked, was only a general law and exceptions were not rare, but it was of practical value in forming a diagnosis. In the case just operated upon he pointed out that gall stones accompanied the malignant growth; they were all small and probably of recent origin, and it was not likely that they had anything to do with the production of the malignant disease; it was far more likely, he thought, that they were themselves produced by the stagnation of the bile in the gall bladder.

The subsequent course of the case was as follows: a large quantity of bile was discharged through the opening, and within a few days the degree of jaundice perceptibly diminished and the amount of bile in the urine also decreased. No improvement in the general condition occurred, though the patient professed himself as more comfortable after the operation. He continued, however, to waste, and death occurred some five weeks later. At the necropsy a mass of carcinoma was found to involve the common bile duct.

Errata.—In last week's "Operating Theatres, 7th and 8th lines, 1st column, for "Enlarged Tonsils, a limp in walking" read: "With a tendency to sway to the left when walking"; next line for "which" read "the pain"; in second line from the bottom 1st column for "mystagmus" read "nystagmus"; 2nd column, for "diplœtic" read "diploëtic"; 7th line from the top 2nd column for "whole" read "hole"; 12th line, for "opening" read "openings"; 29th line, for "labyrinthal" read "labyrinthine"; in 32nd line between "signs" and "due" insert "was"; in 34th line for "also the" read "with an."

TRANSACTIONS OF SOCIETIES.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Meeting held Wednesday, March 6th, 1907.

The President, Dr. Byrom Bramwell, in the Chair.

Dr. J. O. Affleck read a paper on

CLINICAL OBSERVATIONS AND EXPERIENCES; PROGNOSIS AND TREATMENT OF LOBAR PNEUMONIA.

An abstract of this paper will be found on page 309.

Dr. Affleck's paper was followed by a long discussion.

Dr. Byrom Bramwell referred particularly to the abdominal cases, which were often operated on by mistake for appendicitis. He did not think a pulse-rate over 120 so bad a sign as Dr. Affleck did; in his opinion irregularity of the pulse was a much more serious thing. Cases with jaundice, he thought, were not favourable. He agreed that little alcohol was required. Strychnine and oxygen were the two most useful remedies.

Professor Greenfield urged that no remedy was of such use as strophanthus. Twenty years' experience had convinced him that if a reliable preparation, such as the 1888 B.P. Tincture, was given as soon as the pulse flagged, in doses beginning with 5 minims every four hours, heart failure was in many cases efficiently combated. Strychnine was in no sense a heart tonic, and he believed it was dangerous. Digitalis had the disadvantage that it might accumulate and cause poisoning. If strophanthus was used there was no risk of this kind. It should be given with an equal quantity of tincture of capsicum to prevent its disagreeing, and should not be combined with other drugs. He spoke strongly because he thought that strophanthus was a drug which had not received the attention it merited. It was essential, of course, to use an efficient preparation; the ordinary B.P. Tincture was often quite weak.

Dr. James believed that it was useful to give a purge at the outset. In bad cases he had the idea that musk was a useful though expensive remedy.

Dr. Carnegie Dickson also praised strophanthus in pneumonia. He suggested that it might tend to prevent ante-mortem clot.

Dr. Gullaud discussed the prognostic indications which a blood count afforded. A falling leucocytosis was a bad sign, indicating diminishing power of resistance; rise in the leucocytes, on the other hand, was favourable. Cases with marked persistence of eosonophiles usually did well. The glycogen reaction had much the same significance, from a diagnostic point of view, as the polymorphous leucocytosis.

Dr. Wm. Russell thought that strychnine acted beneficially from being a vasomotor tonic.

Dr. Goodall said that he had recently been examining samples of strophanthus purchased in the open market, and found that some of them were absolutely inert and worthless.

Drs. Ian Struthers Stewart and Peel Ritchie read a note on the use of the

OPSONIC INDEX IN THE DIAGNOSIS OF TUBERCULOSIS.

They found that the results of a single examination of the index was unsatisfactory, and gave a considerable margin of error. They had therefore adopted the inoculation method, the routine being to test the opsonic index on several days, give an injection of Tuberculus R, and watch the result on the tuberculo-opsonic index. In healthy persons there was an early rise to a considerable degree above normal; in cases of localised tubercle there was first a fall, then a rise, but not to so high a level as in normal persons. Their observations had been made on several hundred patients, mostly suffering from surgical tubercle, with corresponding controls. The communication was illustrated with charts, &c., showing the results of injection.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Surgery.

Meeting held Friday, February 22nd, 1907.

The President, Mr. H. R. Swanzy, in the Chair.

FRONTAL SINUSITIS.

Mr. Robert H. Woods exhibited three cases of frontal sinusitis subsequent to operation. He described the clinical history of each case, and gave an account of the operative procedure which he usually carried out for the affection. An incision was carried from within outwards along the line of the eyebrow, and the frontal sinus laid open by means of a small trephine, the aperture being subsequently enlarged by means of gouge forceps. The diseased mucous membrane lining the sinus and its recesses was thoroughly removed with a curette. The entire anterior wall of the sinus was not removed, as was generally recommended in the text-books, in order that the scalp might recede and adhere to the posterior sinus wall, because, in his opinion, this step was unnecessary. Obliteration of the cavity could be brought about after removal of the mucous membrane by the growth of granulation tissue from its bony walls which developed subsequent to the operation. Obliteration of the sinus took place first at the infundibulum as the granulations fused first at this narrow outlet. Drainage, consequently, could not be carried out by this passage as efficiently as by means of a tube introduced by the wound.

Mr. P. Dempsy alluded to the difficulty in the complete eradication of sinus infection. There was nothing easier than to alleviate the discharge, and nothing more difficult than to get it to cease altogether.

Sir Thomas Myles referred to the methods of effecting complete obliteration of cavities in bone, and instanced the difficulty met with in securing the obliteration of a cavity in the head of the tibia—for instance, by granulation tissue.

EXHIBITS.

Sir Thomas Myles exhibited a man, æt. 60, in whom a large abdominal tumour could be detected. The patient had been admitted to hospital for injury to his hip, and had not been previously aware of the existence of the tumour. The swelling, which was suggestive of splenic enlargement, was quite painless and dull on percussion. Numerous hypotheses had been advanced as to the nature of the tumour, but none seemed satisfactory.

Sir Thomas Myles also exhibited a young man, æt. 21, who presented warty growths on both legs. The growths were somewhat painful, and seemed to him to be examples of a rare type of malignant disease, originally described by Hawkins as warty tumours of cicatrices.

Mr. Edward H. Taylor regarded the case as one of warty tuberculosis of the skin, and thought the best form of treatment would be excision, followed by Thiersch grafting.

Mr. Charles Maunsell and Mr. Alexander Blayney regarded the growths also of a tuberculous nature.

Mr. C. A. K. Ball exhibited a gangrenous gall-bladder. The patient from whom it was removed had been sent to hospital as a case of perforated typical gastric ulcer. On admission the patient presented symptoms of general peritonitis, originating probably in the appendix. An incision in the right iliac fossa revealed free blood-stained fluid; the appendix was slightly inflamed, and the cæcum was both inflamed and thickened. Another incision was made below the right costal arch, and a tumour resembling a kidney came into view. It proved to be a distended and gangrenous gall-bladder adherent to the colon. A small concretion was found blocking the cystic duct. The gall-bladder was removed, and the upper abdominal region flushed out. The patient recovered, and her stomach symptoms were relieved. The contents of the gall-bladder were submitted to bacteriological examination, but were found sterile.

Mr. Alexander Blayney exhibited a specimen of Meckel's diverticulum which he had resected. The previous history of the patient pointed to severe attacks of pain, which rendered life miserable. Mr. Blayney thought that these attacks were due probably to slight intussusceptions, occurring from time to time of the diverticulum into the intestine.

Mr. Charles Maunsell alluded to similar cases in his own practice.

Sir Thomas Myles exhibited various specimens of surgical interest, including (*a*) a renal tumour developing from a "supra-renal rest"; (*b*) malignant growth of the testis; (*c*) a pathological vermiform appendix; and (*d*) an extracapsular fracture of the neck of the femur.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

Meeting held Thursday, March 14th, 1907.

The President, Priestly Smith, F.R.C.S., in the Chair.

Dr. Rockliffe read notes of a case of

THROMBOSIS OF THE CAVERNOUS SINUS

associated with septic meningitis, which originated from a septic sore on the lip. The patient was a fish dock labourer, whose general health, but for bronchitic attacks, had been satisfactory. He was first seen on November 18th last, and had protosis of the right eye. Five days previously a small spot appeared on the upper lip. He picked it, and eventually pricked it with a pin. The lip and face became swollen, and he then applied a linseed meal poultice. Four days later he was admitted into the Infirmary. He became delirious, and a diagnosis of thrombosis of the cavernous sinus was made. Afterwards lumber puncture was done. He died on November 20th, being two days after admission, and seven days after the spot appeared on the upper lip.

At the autopsy the meninges about the right cavernous sinus were covered with lymph. The right cavernous, the transverse, and part of the left cavernous sinus were thrombosed. The orbital tissues on the right side were inflamed and swollen, but there was no pus.

Dr. **Rockliffe** also read notes on four cases of

SYMPATHETIC IRRITATION,

occurring after 18, 22, 28 and 50 years. In two of these cases a foreign body was found, and the third case probably contained a foreign body, a piece of stone. The injury in the fourth case was a punctured wound. Considerable ossification was present in three of the cases.

Mr. A. R. **Brailey** read a paper on

CYSTS OF THE PARS CILIARIS RETINÆ.

He stated that these structures had frequently been mistaken for sarcomata of the ciliary body clinically, but little was known of their pathology, though their study might throw some light on the secretion of the aqueous. They were found in such a variety of conditions that he was only able to classify them according to their apparent mode of origin. Two changes which played an important part in the origin of some varieties limited to the cells of the unpigmented epithelium were multiplication of the cells, and vacuolation of the cell bodies. This proliferation was most frequently found in senile eyes, and was commonly associated with hypertrophy of the ciliary processes. The cells of the pigmented layer appeared to play a more passive role, and even in cysts arising by simple detachment of the epithelium, it was the unpigmented layer alone which was affected, the adhesion between the pigmented epithelium and the underlying ciliary body being a peculiarly intimate one. The different modes of origin appeared to be: (1) Detachment of the non-pigmented epithelium. (2) Proliforation of the non-pigmented epithelium cells with the formation of a cavity arising either by simple separation of the cells, or by their vacuolation and destruction. (3) Proliforation and union of the cells of adjacent processes, leading to a portion of the posterior chamber being shut off from the remainder.

The number of the specimens was too small for him to come to any conclusion as to the relative frequency of these varieties. The contents of the cysts was usually lost during the preparation of the specimen but when present it consisted of a deeply-staining homogeneous coagulable fluid.

LIVERPOOL MEDICAL INSTITUTION.

Meeting held Thursday, March 14th, 1907.

The President, Mr. **Frank T. Paul**, F.R.C.S., in the Chair.

NEPHRECTOMY FOR RENAL SARCOMA IN CHILDREN.

Mr. K. W. **Monsarrat** read a paper on two cases with remarks on the pathology and the recent results of surgical treatment. The first case was that of a boy, æt. 3 years, the signs of disease being hæmaturia and abdominal tumour. The growth removed weighed 2 lbs. 6 ozs. The child recovered from the operation but died from recurrence in six months. The growth was a sarcoma containing tubules and striated muscle fibres. The second case was that of a boy, æt. 5 years, with abdominal tumour and hæmaturia. The child recovered from the operation and remained well at the end of six months. The growth weighed 2 lbs. 2 ozs. and was a pure round-celled sarcoma. Mr. Monsarrat found that published records indicated the occurrence of hæmaturia in about a third of the cases. He presented a statistical study of 104 cases published between the years 1897 and 1905 inclusive. These records showed that the present mortality from operation was 26 per cent., and that to the number of complete recoveries a total of seven had been added during the years examined. He considered that operation was justifiable in cases which showed no evidence of metastasis.

The President, Dr. Percy Marsh, Mr. R. W. Murray and Dr. Stookes discussed the paper.

PLEXIFORM NEUROMA.

Mr. G. G. **Hamilton** showed a patient from whom he had removed a large plexiform neuroma. There were about 62 cases on record. This one grew from the iliohypogastric nerve and was incorporated with the neighbouring muscle. It measured 10 by 41½ inches and showed numerous strands of nerve thickened to the size of a toothpick and many of them coiled up into little capsules. There were very few axis cylinders present, the whole nerve being simply a mass of thickened gelatinous endoneurium.

Mr. Hamilton's communication was illustrated by several lantern slides. The pathology of the condition was discussed by Dr. E. E. **Glynn**.

VARIATIONS IN THE NORMAL TEMPERATURE.

Dr. W. **Carter** read a short note on the above subject. After recalling the facts that Ogle and Liebermeister had recorded fluctuations varying from 1.8 to 2.3 Fahr. in 24 hours, and that Dr. Finlayson had observed that aged people in the Glasgow Workhouse Infirmary who died without any definite disease generally sank at the time when, in normal health, the body temperature was lowest, stated that on two occasions at distant intervals he had been able, by the co-operation of the Matron and night nurses of the Royal Southern Hospital, to see if an inversion of the ordinary periods of night and day duty affected the normal rise and fall. Each nurse, towards the end of her period of three months night duty, took her temperature three-hourly, when not asleep in the day; but as the charts, which were shown, proved, the normal depression which took place under ordinary conditions of life at about 3 a.m. remained fairly constant even after three months of turning night into day and *vice versa*. It seemed, therefore, to be deeply impressed on the organism, and independent of external circumstances, so far at least as the trial of three months tended to establish the fact.

Sir **James Barr** doubted if the records of nurses' temperatures taken by themselves could be implicitly relied upon.

A New Astigmometer.—Dr. K. **Grossmann** explained the mechanism of his Astigmometer and demonstrated a working model; a description of the appliance will appear in due course, illustrated by diagrams.

THE SURGERY OF WARFARE AND CATASTROPHE.

Dr. **Arthur Evans**, in an interesting lecture, illustrated by numerous lantern slides from photographs and radiographs, taken during the Boer War, and after the earthquake in Jamaica, drew attention to the great contrast between the conditions under which surgery was practised in modern wars, and those which obtained in sudden catastrophes such as an earthquake. In the one every contingency was foreseen and provided for and the organisation was perfect beforehand; while in the other, all aid had to be organised under the most appalling conditions and literally without a moment's notice.

The **President** proposed a vote of thanks to Dr. Evans for his lecture and of congratulation upon his escape from the earthquake and the great services he had been able to render to the injured. The vote was carried by very hearty cheers.

The third Latin American Medical Congress was opened at Monte Video on March 17th. About 100 delegates were present, representing all the Latin American countries. Sittings will continue throughout the week.

ULSTER MEDICAL SOCIETY.

Meeting on Thursday Evening, March 14.

The President, Dr. D. P. Gaussen, in the Chair.

Professor Milroy read a paper on the "Movements of the Stomach," based on experimental research with dogs. He said that there was a regular peristaltic wave towards the pylorus, which was excited by pressure, such as the presence of food. If only fluid was present there was no reverse peristalsis; but if there were solid there was a reverse peristalsis also. The fundus showed a tonic contraction, a much slower wave with smaller waves superadded. Salivary digestion he had found to continue for two hours in the fundal portion of the stomach. The peristaltic action depended on nerve ganglia between the muscle coats. If the external muscle coat is separated, the ganglia are removed, and the internal muscular coat does not show the peristaltic action. If a ring of the muscular coats is removed right round the stomach, leaving the mucous membrane intact, the peristaltic wave is not stopped, but jumps the gap. In vomiting, leaving abdominal action out of the question, two factors were always present—reversed peristalsis and relaxation of the cardiac orifice.

Professor Milroy also gave a demonstration of the "Vascular Supply of the Central Nervous System."

In the Anatomical Department, Dr. C. G. Lowry showed sagittal sections of the trunk, and a case of single kidney. Dr. P. T. Crymble showed specimens illustrating the air sinuses connected with the nose, and Mr. H. Cunningham showed specimens of the middle ear.

In the Pathological Department Professor Symmers and Mr. Cunningham showed some Eye specimens. Drs. Houston and Rankin showed examples of opsonic indices with various microbes, and Dr. Wilson read a short paper on "The Value of the Widal Test, as Ascertained by its Use on 230 Occasions," and also notes on a new method of isolating the bacillus typhosus from water.

Professor Sinclair showed a specimen from a case of umbilical hernia exhibiting numerous constrictions and gangrenous patches. Dr. Dempsey showed several gynæcological specimens, and Dr. Darling showed the brain, cord, &c., from a case of cerebro-spinal meningitis.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, March 17th, 1907.

Treatment by Ions.

It would seem that the future is more and more, even in medicine, reserved for electricity, or at least a more complete knowledge of its laws must develop a new horizon for the healing art. It is thus that we are on the eve of a complete revolution and are given seductive promises regarding ionic medication.

Everyone knows the principle of galvano-plasty; that is to say, the properties possessed by an electric current passing through a saline solution decompositing the dissolved salt. Take, for instance, a bath separated into two compartments by a porous partition and filled with a solution of sulphate of copper. If an electric current is passed through the solution the sulphuric acid is let free by the positive pole while the metal is freed by the negative pole. The positive pole is called anode, and the negative cathode.

A displacement in an inverse sense of the molecules of the sulphuric acid and copper takes place thus in the bath, the copper metal travelling, so to speak, from the cathode to the anode; that is to say goes up the current and the acid going from the anode to the cathode, or descends the current.

The name of ions (travellers) is given to these elements separated by electrolysis.

What happens in a saline bath can also happen in the human body the organism of which is impregnated with saline solutions. The blood itself contains a large quantity of chloride of sodium, and consequently the body, or living tissues, may be considered as electrolytes (the name given to the sulphate of copper solution), and that the conductibility of the human body is nothing else than electrolytic conductibility.

If an electric current were passed through the body, and that between the metal plates, platinum, for instance, a solution of iodide of potassium were interposed, the metal ion or potassium would be set free by the anode and would penetrate into the body to pass to the cathode, while the iodine would take the return journey.

Consequently it is possible, by means of this method, to introduce a drug to any particular part of the body, where it is required to act, and there only and with a regularity and surety without precedent in therapeutics.

It is thus there can be produced at will local action on the skin or general therapeutic action in the organism, according to the electrolytic solution employed, the intensity and the duration of its application.

Professor Leduc, the initiator of ionic medication, says that "in some future time the present treatment by which, in order to act on a very limited part of the body, we introduce into the whole organism noxious substances, particularly injurious to the most delicate tissues, the nerve centres, for instance, will appear grossly absurd. One of the aims of medicine should be to replace as much as possible general by local treatment."

The treatment by ions is a purely local treatment. The medical agents it introduces into the organs reach the morbid tissues directly, very few of them entering the general circulation, as has been proved by experiments with salicylate of soda.

However that may be, it has been already proved that one of the most constant and efficacious actions of this electrolytic treatment is its resolving influence on fibrous formations by means of electrolysis of chloride of sodium. Complete ankylosis of the articulations got well rapidly under its influence and without forced extension or pain.

It would be impossible to give here all the cases in which the ionic treatment has been successful in the hands of Dr. Leduc.

It would seem, in any case, to be particularly successful in pleural affections, painful pleuritis, dry pleurisy, and above all, pleural symphysis. Remarkable results were also obtained in the treatment of neuralgia, tic doloureux of the face by salicylic ions.

Professor Leduc affirms having cured a case of neuralgia of four years' standing, and for which every other treatment had been tried in vain.

One of the drawbacks to this new method lies in the special instruments required and the necessity of long and laborious experiments to understand the local effects (caustic, antiseptic, coagulating of the conductibility, vitality, &c.) of the different ions. Their local action varies not only with each kind of ion but also with the dose of the same drug employed.

Intravenous Injections of Collargol.

Intravenous injections of collargol have been employed with success in numerous cases of septicœmia, and they deserve to be more generally employed. The *modus operandi* is simple. A bandage is placed above the elbow and sufficiently tight to distend the veins; an ordinary hypodermic syringe, previously sterilised, is charged with the collargol solution (2 per cent.). The needle is passed obliquely into the vein in the sense of the blood current, and as soon as the blood flows from it the syringe is adjusted and the liquid injected. After which the needle is withdrawn

The only accident that might happen in this little operation is that of missing the vein and injecting the solution into the surrounding tissues. To avoid this it is sufficient to wait until a drop of blood flows from the needle, to be certain that no error is made.

According to Riobald these intravenous injections of collargol are very successful in certain cases of acute arthritis rebellious to all internal treatment. Of fifteen cases thus treated by him, a complete cure was obtained in eleven, and the remaining four were greatly improved. The general condition appears also to be considerably modified by these injections; the temperature falls in a few hours.

This method cannot supersede, however, the treatment by salicylate of soda of acute rheumatism; but in those sub-acute cases, and especially in gonorrhœal rheumatism, it possesses almost a specific action.

This treatment might be associated with the Bier method: an elastic band tightly wound above the joint until complete cyanosis of the parts is observed; that is to say, from one to two hours, and repeated twice a day.

As has been mentioned, the strength of the solution is 2 per cent., and from 4 to 8 syringes might be injected the first time, and increased to 6 or 10, and repeated every day until relief is produced.

If at the end of two or three days there is no improvement it is better to suspend the treatment. However, failure is rare.

Tuberculous Meningitis in Children.

The treatment consists in mercurial frictions and iodide of potassium, given in large doses internally.

Iodide of potassium, grs. 20.
Syrup of orange, dr. 3.
Water, oz. 3.

A teaspoonful every hour.

Ice to the head; a flying blister followed by rubbing in with iodoform ointment (1-10).

Syrup of iodide of iron.
Syrup of lactophosphate of lime.
Syrup of cinchona.
Antiscorbutic syrup.
} āā oz. 2.

Three tablespoonsful a day.

In case of agitation, convulsions, warm baths and

Bromide of potassium, gr. 10.
Hydrate of chloral, gr. 6.
Syrup of peppermint, dr. 3.
Water, oz. 1.

A teaspoonful every hour.

Calomel in fractional doses (6 gr. in 10 powders) every hour. Constipation should be treated by suppositories, castor oil scammony or enemas with glycerine.

The patient should be shielded from the light and fed on milk and beef tea.

The lumbar puncture is especially useful as an aid to diagnosis.

GERMANY.

Berlin, March 17th, 1907.

Accidents and Cardiac Diseases.

Through the Insurance laws the determination of the relationship between accidents and subsequent disease of the heart has become an important one to the professional expert. The subject has been recently treated in the Argt. Sachverst Zeitung by Prof. Strauss, of this city. The paper is based on cases observed clinically by himself. The diseases mentioned in the paper are four in number. (1) Traumatic endocarditis; (2) serious muscular insufficiency; (3) sensible symptoms of irritation; and (4) arteriosclerosis. As regarded the first form the writer observed a case in which a brewery workman held on to the rim of a vat with all his force in order to prevent being pitched head foremost. After some weeks shortness of breath came on, which got worse, and although he was months in bed in hospital the case ended fatally. The autopsy showed warty deposits on the mitral valve, hypertrophy of the left ventricle with dilatation of the right. The following points were in favour of a causal connection between the cardiac disease and the accident. The nature of the accident rendered the occurrence of the mitral lesion quite possible, the continuity of the symptoms from the time of the occurrence of the accident might be held to be proved.

2. Excessive muscular insufficiency without coarse lesion of either valves or muscles or pericardium. These might also occur. A turner was struck whilst at work at his lathe by a tool that flew off and hit him over the heart. He first became giddy, then lost his breath. On being admitted into hospital the symptoms of cardiac muscular insufficiency and dilatation of both sides of the heart were observed. The symptoms at first improved, but they got worse again and the man died. A post mortem showed dilatation without any valvular changes, but there was narrowing of the aorta. This latter condition, in the writer's opinion. rendered the dilatation worse. The injury, however, might be looked upon "as the exciting cause of the pain and disturbance of health of the patient."

Simple straining with a narrowed aorta might lead to symptoms of muscular insufficiency. To prove this it would be necessary to prove the patient's perfect health up to the moment at which the strain took place, that this was excessive, and that no other explanation of the disease was possible.

In all cases of muscular insufficiency, pericardiac symptoms and aneurysm should be looked for. As regarded the first, a systolic murmur should be looked for at the apex, and a diastolic tumultuous movement of the chest wall. For the aneurism X-rays would have to be made use of.

3. Cardiac pain, pressure over the heart, and complaints of accelerated movement of the heart, without any abnormal pathological condition. The causal connection between the accident and the symptoms was first brought into consideration by the statement of the patient himself, if reliable. All the methods of examination that were employed in determining undue irritability were to be made use of. Orthostatic tachycardia, if present, should be noted, the conditions of the pulse when the patient had risen quickly off a chair. Herz's test (acceleration of pulse whilst stretching the flexed arms), the Hering-Kratschmer trigeminal reflex (the effect on the heart of ammonia vapour on the nasal passages), the Mankopf, Rumpft and Erb's tests. Only the positive failure of the tests was of any value, but they should all be applied and their value appraised.

4. Arteriosclerosis. This could only come into question in so far as a latent arteriosclerosis might be made manifest through an accident. The possibility must also be conceded that the origination of an arteriosclerosis might be accelerated by a long standing general neurosis.

Cardiac Activity and Blood Pressure Influence from Points Tender on Pressure.

Prof. Rumpf, of Bonn, has an article on this subject in the *Munich Med. Wochensel*, 4, 1907, from which the following note is gathered. In many cases of general neurosis in which neuralgia or tender points are present, changes in the cardiac activity and in the circulation may be effected by irritation of such points. These changes are: (1) simple acceleration of the heart movements; (2) transient preliminary slowing of the beat with subsequent accelerations; (3) weakening of the beat; (4) sometimes irregularity of the pulse, or intermittency in the beat; (5) distinct cyanosis of the face; (6) lowering of blood pressure; (7) raising of blood pressure.

All these changes in cardiac activity and in that of the vessels have this in common, that on ceasing the pressure on the tender points the changes ceased soon afterwards. The pulse rate was the first to return to the normal, whilst the change in the blood pressure were recovered from more slowly. In relation to general pathology the change in the blood pressure, by pressure on the tender point, was of special interest, as both the lowering and the raising of the pressure threw light on many pathological symptoms.

The Aetiology of Eclampsia.

A contribution to this interesting and obscure subject has recently been made by Dr. Brauns, *Deutsche Med. Zeitung*, 17.07. The first case observed was that of a woman who, previous to pregnancy, had been perfectly healthy. There was nothing whatever to indicate that she had had any nephritis before this. Both in the sputum and in the urine tubercle bacilli were present. In nine other cases of eclampsia also there were "splinters," *i.e.*, pannula globular elements that had been split off from the parent body of a tubercle bacillus. The writer considers the discovery of these splinters as proof of tuberculosis of the kidney. With the increase in the quantity of urine after delivery the number of "splinters" diminished, but even for months afterwards individual and extra cellular fragments could be shown to be present.

AUSTRIA.

Vienna, March 17th, 1907.

Theory of the Exanthem in Variola.

At the "Gesellschaft" Pirquet endeavoured in a long paper to show that the eruption in small pox was due to the agglutination taking place in the capillaries that produced the pustules. In previous vaccination the variola poison is modified by some bacteriolytic action produced by the vaccine, but when the vaccine itself was introduced fever and areola follow on the eighth or tenth day with undeviating regularity, thus proving the presence of a toxic agent, after which an antitoxic condition is produced. By inoculating smallpox a similar state is induced with the peculiar exanthemata. From this it follows that there is a connection between the antitoxin and the exanthem, as it is not until the antitoxic or immune condition is produced the rash appears on the cutaneous surface.

Is this antitoxin which produces the exanthem the agglutinin floating in the circulation and coagulating the blood in the capillaries producing congestion, inflammation, and finally pustules? This theory appears to explain Weigert's histological discoveries, who found the efflorescent patches on the skin contained in the arterioles tubular zoogl œa masses which was probably the result of the agglutinin. Measles again have apparently the same agglutinating bacteria in operation with incubation, prodromal fever and a leucocyte curve similar to that met with in small pox, which also supports the theory of the antitoxic exanthem.

Kraus thought this new theory violated the logic of our knowledge of immunity in variola by vaccine. He considered the exanthemar rash to be the result of a general toxic condition and not depending on the formation of a new endotoxin as Pirquet suggests. It is simply a generalisation of the virus, as that occurring in typhoid, syphilis, etc. Another point against the new theory is that no agglutinin or precipitin have been discovered in variola, although observed in typhoid, which leaves the theory without support. Again the doubtful immunity of vaccination renders speculation on the lytic properties of any newly-developed antitoxin or properly or more correctly endotoxin, a dangerous adventure.

Escherich thought this new idea of Pirquet's should not be passed by lightly, as it opened up the consideration of a very difficult subject. It has frequently been observed that the strong have a more intense rash than the weak in attacks of measles, while undeveloped or dark-coloured exanthems is a signum mali ominis.

Pirquet's hypothetical, endotoxin may not be the cause of the rash, but it is a good explanation of the resisting constituent of the organism.

Knopfelmacher reminded his hearers that the exanthems of the immune and non-immune behaved very differently after injections, and quite agreed with Pirquet's theory of the agglutinin producing the rash.

Neuritis Optica.

Reiter and Lauber showed a case of neuritis of the optic nerve following an attack of typhoid fever, which they pointed out as very rare, as only twenty such are to be found in medical literature. They considered the case as one of descending neuritis from the meningitis that preceded the advent. In other cases the poison may be the cause, and pure toxic neuritis result. Salomon said that in the different infectious diseases such as scarlatina, typhoid, etc., which he had examined he always found a certain amount of congestion in the papilla.

Lauber said this case was not a congested papilla, but a genuine neuro-retinitis. Wenternitz and Schrötter expressed their surprise that this complication was so rare, as they had been many years among these infectious diseases and had not seen one before.

Noorden was inclined to believe that the toxin was the active factor in these cases, as he had frequently, like Salomon, observed congestion of the papilla as a complication which he associated with the disease.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Report of the Carnegie Trust.—The following are the main points in the report of the executive committee concerning the administration of the Trust during 1906:—Under the scheme of allocation of £40,000 annually for five years among the four universities, £37,288 has been handed over during the year. Grants have also been made to the following extra-mural schools:—School of Medicine of the Royal College, Edinburgh Medical College for Women, Anderson's College Medical School, Glasgow Technical College, Heriot Watt College, West of Scotland Agricultural College, East of Scotland Agricultural College. To these institutions £9,000 has been allotted. Under the Research Scheme appointments were made to 17 Fellowships and 37 Scholarships, and grants were given to 40 applicants. A list of the published researches of beneficiaries under the scheme has been prepared. In the Royal College of Physicians' laboratory 29 workers have carried out investigations during the year; a tenth volume of laboratory reports will soon be issued. In the last report the executive committee drew attention to the financial difficulties which then faced them in relation to the payment of class fees, from the multiplication of classes and the raising of the fees in certain arts classes. The Trust was, in fact, nearly at the end of its resources, and had therefore to reconsider the regulations; they resolved, as a provisional measure, to adopt two modifications which appeared to be called for also upon educational grounds. The one modification limited payment of fees for further classes to beneficiaries who had passed their graduation examination up to that date, and the other restricted the payment of fees for advance classes to those who had proved their ability to profit by such by passing the ordinary graduation examination on the relative subject. This year, despite the rise in arts fees, the expenditure has diminished by £6,563; it is not possible to say how far this relief to the Trust has been at the expense of the Universities, and how far at the expense of beneficiaries. The number of beneficiaries has been 2,911, as opposed to 3,184 in the previous winter session. The time for a second quinquennial allocation of funds under Head A of the Trust Scheme is now approaching, as the present five-yearly period terminates in 1907. The following general considerations will influence the new allocation of grants:—(1) The wishes and requirements of each educational centre will be considered as a whole, so as to avoid, as far as possible, duplication and lack of co-ordination; (2) an attempt will be made to come to some arrangement as to an inclusive fee to be paid by the beneficiaries for their whole education. (3) Some of the present educational difficulties and anomalies will be removed by Ordinance.

CLOSING OF GIRGENTI HOME FOR INEBRIATES.—The Glasgow Corporation have arranged to close this Home, which has now been in operation for six or seven years, and to transfer the inmates to Perth. The Home was started experimentally, and through its agency a number of women have been reclaimed, but it is not felt that the results justify its continuance at a cost of nearly £1,300 a year. The Home Secretary has intimated that in future the grant is to be diminished and this, no doubt, has influenced the city authorities in coming to their decision.

THE BIRTHPLACE OF A GREAT QUACK.—It is of some interest to learn that Edinburgh has the honour(?) of having produced one of the great charlatans of the nineteenth century. "Prophet" Dowie, whose death was recently announced, was the son of John Dowie, a breeches maker, and Ann MacFarlane, who sixty years ago resided in Leith Street. The following entry in the Register of Births, 1855, attests the facts: "Edinburgh, December 31st, 1855—John Dowie, breeches maker, and Ann MacFarlane, his spouse, had a lawful son born at Leith Street, St. Andrew's parish, on the 23rd day of March, 1847, named John Alexander."

BELFAST.

ULSTER HOSPITAL FOR WOMEN AND CHILDREN.—The annual meeting of this hospital was held last week, the Lord Mayor (the Right Hon. the Earl of Shaftesbury, K.C.V.O.), presiding. The medical report, read by Dr. Fielden, showed an increased number of patients in all three departments, Children's, Women's and Maternity. The number of children treated in the wards was 247,174 operations were performed, and there were 10 deaths. The women treated in the wards numbered 81, there were 63 operations and two deaths. The extern maternity cases numbered 260, and the total number of patients to whom the hospital afforded relief was 3,787. The medical staff reported with regret the resignation of Dr. Cecil Shaw, who had been Ophthalmic Surgeon to the hospital for 15 years, and secretary of the staff for 13. He had been obliged to resign owing to the pressure of other duties, but had been elected to the honorary consulting staff. Dr. A. B. Mitchell spoke on the work of the hospital, and explained the great need for further and improved accommodation. A movement has been started to rebuild the hospital, and a start has been made with a promise of £1,000 by Mr. G. W. Wolff, M.P., towards the total of £10,000 which it is estimated will be needed.

THE UNIVERSITY QUESTION.—A meeting of the Council of the Royal University Graduates Association was held last week, at which certain resolutions were passed condemning Mr. Bryce's scheme. They also "condemned in the strongest manner the extraordinary conduct of the thirteen members of the Senate who withdrew their opposition to a scheme which four months ago they declared to be disastrous to the interests of education and gravely injurious to the welfare of the country." In view of the frequent paragraphs in the daily press referring to the Presbyterian Church and University education it may be as well to say that the views and resolutions of the General Assembly's Committee on the subject need not be taken too seriously, as they do not represent any very large body of Presbyterian opinion. The Ulster Presbyterian is a singularly independent individual, and forms his opinions on University as well as other matters without any ecclesiastical guidance, and even among the clergy of that church there are wide diversities of opinion on this question.

CEREBRO-SPINAL MENINGITIS.—About twenty new cases of cerebro-spinal meningitis have occurred during the past week, and seven deaths. In one case, where a child of four months old had died without medical attendance, an inquest was held. It appeared that five weeks ago another child in the same family had died of cerebro-spinal meningitis, and from the *post-mortem* appearances it was evident that this child died from the same disease. The father was a labourer earning eighteen shillings a week, and the family of six occupied one room, at a rent of 1s. 4d. a week. The whole place was horribly filthy, and the court where the house was situated had been closed as insanitary, but opened again. It is a good case for the present Health Commission to investigate, specially as to why the house was allowed to be occupied after being condemned. The members of the Health Commission have been making various visits and inspections in the city, and will sit again on Tuesday, 19th.

LETTERS TO THE EDITOR.

MEDICAL LAW REFORM.

To the Editor of THE MEDICAL NEWS AND CIRCULAR.

SIR,—In reply to your correspondents who ask what practical steps can be taken to promote the appointment of a Royal Commission, I would suggest that the first thing to be done is to start a medical Law Reform Association or Committee, and to provide them with the necessary funds to begin with. The job would be a big one, but it is well within the power of the profession to carry it through if only they will unite and act with determination. They could show that it is their duty to take up the task on behalf of suffering humanity, and could establish their case for legislation on overwhelming evidence. Quackery, practiced by unqualified pretenders, and the traffic in quack nostrums, form a gigantic system of cruel fraud, which in the present state of the law cannot be interfered with. Exposure would kill it; but the exposure must be complete and indisputable. My personal position is one of almost complete detachment. Personally, I am not remotely affected by the evils I complain of. My knowledge of them and my acquaintance with problems of medical legislation have gradually grown during the past thirty years. During this time I have learnt to pity the victims of cynical villainy, and to detest the criminal gangs who amass wealth by this the most nefarious of methods. I also sympathise with the profession, whose status remains inferior largely in consequence of their lack of due privilege and protection. When I first broached my project of a Royal Commission I offered to back my opinion as to its efficacy to the amount of £50; and I am ready to renew this offer on the same terms. If ninety-nine others can be found to put down a like sum, or if the balance of £5,000 can be guaranteed, I will make myself responsible for the amount named; and I will leave this offer open for a year from this date. It seems useless to discuss further procedures until we see what response my proposal elicits.—Yours truly,

HENRY SEWILL.

March 13th, 1907.

VOLUNTARY *v.* STATE HOSPITALS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,

PROPOSITION A.

That the hospitals should be associated in their management with the Borough Councils.

Let it be granted that the health of the community is the concern of the State (the State here means the civitas, the city, town or borough).

Also that voluntary hospitals are maintained for that end, namely, health. Therefore the Borough Councils should recognise and encourage voluntary hospitals, in so far as they tend to the well-being of the community, and should prevent them from doing harm economically.

It follows: (1) That the hospital will be free of rates, for no rate is levied on the Town Hall, or the Free Library, or the Workhouse Infirmary. (2) That the State, *i.e.*, the Borough Council, will assist in and control their management. For (*a*) the health of each individual concerns the community as a whole; and (*b*) the committees of hospitals must act in harmony with the other work of the Council. The Council will therefore appoint a proportion—one-fourth or one-third—of the board of management of every hospital within the borough, and the accounts of the hospitals will be audited by the Borough Accountant.

It will follow that when the voluntary subscriptions diminish or cease, the hospital will be, in part or wholly, closed. For if it were then to be rate-aided, it would cease to be a voluntary hospital and would become a Workhouse Infirmary, to which the principles and rules of the Poor Laws would apply.

I am, Sir, yours truly,
March, 1907. John Euclid.

THE *PALL MALL GAZETTE* ON INSANITY.

To the Editor of The Medical Press and Circular.

Sir,—Can nothing be done to bring home to the minds of newspaper editors the gravity of their responsibility to the public in many medical matters. I enclose a cutting from the *Pall Mall* of this evening, March 9th, and I would ask whether it is right for a paper of the highest class like this to point out a misleading string of paragraphs in such a sensational fashion. I know nothing at all about Dr. Hollander or his works, and assume he occupies the position of scientific distinction the *Pall Mall* assigns to him; he must surely be disgusted to find himself forced into public notoriety in this way, and will, no doubt, hasten to take steps to disavow any knowledge of the transaction.

I am, Sir, yours truly,
An Obscure Practitioner.
March 9th, 1907.

ANTIVIVISECTIONISTS AND FALSEHOOD.

To the Editor of The Medical Press and Circular.

Sir,—May I venture to protest against an expression of opinion found in your issue of March 13th, to the effect that Antivivisectionists "positively revel in wild and wicked exaggerations, and do not scruple even to tell the grossest falsehoods," etc.

Antivivisectionists are fallible, and may make mistakes, but I believe even the medical papers have sometimes gone astray in matters of fact, and even apologised for unintentional inaccuracies. Surely it would be more charitable and certainly more just to believe that when an antivivisectionist falls into an error he does so inadvertently. Although we all feel a certain temptation to apply such adjectives as "cruel" to men who undoubtedly do cruel deeds, most responsible antivivisectionists carefully abstain from doing so, and reserve their adjectives for the deed rather than the doer.

You appear to feel no such scruples when attacking us, and I think a little consideration will induce you to withdraw at least one very objectionable remark in the article to which I allude, and which is certainly more extreme and more insulting than anything that has been written on our side against vivisectors. I refer to the following sentence:—"The honest man has no place in any of the Antivivisectionist organisations of our time." Those who are acquainted with medical men, who, holding Antivivisection views, do not scruple to say so publicly, and thus expose themselves to attacks from their own profession, which cannot be pleasant, and to calumnies in the medical press such as that which I have quoted, cannot but feel that these men at least deserve the epithet "honest," which is the smallest recognition that can be accorded to them by those who hold opposite views.

I am, Sir, yours truly,
B. E. Kidd,
Secretary British Union for the Abolition of Vivisection, 32, Charing Cross, S.W.

OBITUARY.

SAMUEL BARKER, M.D., M.R.C.S.Eng., L.R.C.P. Edin.

We regret to announce the death on March 11th, of Dr. Samuel Barker, of Brighton. The venerable physician was one of the founders of the Children's Hospital, and to the end of his days he remained actively associated with it as Consulting Physician. Dr. Barker had ceased his private practice nearly twenty-five years, and he lived to see his 86th year. For some time he had been failing from old age. He enjoyed brilliant distinction in his profession, and held the degrees of M.D., St. Andrew's (1858), L.R.C.P. Edinburgh (1861), and M.R.C.S. England, and L.M. (1857). He devoted himself chiefly to the study of children, and his services to the Hospital in Dyke Road were appreciated at the highest value. Among his best-known publications were: "Prevention and Cure of Skin Diseases by Heat and Fumigation" "The Turkish Bath in the Treatment of Disease," "Diet of Infancy and Childhood" "Domestic Management of Infants and Children in Health and Disease," "Remarks on the Only True Foods for Children," and "Scarlatina: Its Successful Treatment." It was about fifty years ago when he came to Brighton, and he always commanded a high position as a professional man in the town. The Children's Hospital was not the only public Institution which claimed his interest. For years he was physician to the Brighton and Hove Dispensary, and subsequently was made Consulting Physician. He was also Hon. Physician to St. Mary's Hospital, Queen's Square, Brighton. Dr. Barker was a Fellow of the Royal Meteorological Society.

WILLIAM A. F. BATEMAN, M.R.C.S., L.S.A.

By the death of Dr. W. A. F. Bateman, Richmond (Surrey) has lost its oldest medical practitioner, and one who has for forty years taken a leading part in philanthropic and literary movements in the town. Dr. Bateman, whose death followed an operation, had reached the age of 72, and was one of the first members of the Richmond Hospital, of which he was the senior member of the honorary medical staff. It was largely owing to his energy that the extension of the hospital and the erection of a children's ward were undertaken. He was also Surgeon to the Royal Female Naval School at Isleworth and to the Orphan Home, Ham Common. He had been a keen volunteer, but he retired some years ago with the rank of Surgeon-Lieutenant-Colonel with Volunteer Decoration.

ROBERT ELLIOT LITTLE, M.B., C.M.Edin.

We regret to record the death in Duns Hospital on March 11th, of Dr. Robert Elliot Little, who was spending part of his furlough from Nigeria with friends in Berwickshire. Dr. Little was a native of Wamphray, and was related to Professor Charteris. He was a graduate of Edinburgh University, and was for a number of years in practice in Gordon, Berwickshire, but left some five years ago for service in Nigeria, and was spending a holiday with his friends in Gordon, where he contracted pneumonia. At first there were good hopes of his recovery, but he had a relapse on the following Sunday, and died. He was unmarried.

ARTHUR ERNEST SANSOM, M.D.Lond., F.R.C.P.

We much regret to record the death of Dr. Arthur Ernest Sansom, M.D., who died at Bournemouth, at the age of sixty eight. He was educated at King's College, London, and in 1859 took the M.B. degree, London, and was admitted a member of the Royal College of Surgeons, England, and a licentiate of the Society of Apothecaries. In 1866 he proceeded to the M.D. degree, and in 1878 was elected a Fellow of the Royal College of Physicians, London. Dr. Sansom was consulting physician to the London Hospital and to the North-Eastern Hospital for Children and physician to the Royal Albert Orphan Asylum, and had formerly been examiner in medicine for the Royal College of Physicians, London, and the Royal College of Surgeons, England, and also for the Universities of London and Durham, and physician to the Royal Hospital for Diseases of the Chest, City Road. He was a Fellow of King's College, an ex-President of the Medical Society of London, and a member of various learned societies in this country and abroad. He contributed largely to medical literature, his chief interest being centred in diseases of the heart, in which he was universally regarded as one of the greatest living authorities.

SPECIAL ARTICLE

THE SECOND CONGRESS OF THE INTERNATIONAL SURGICAL SOCIETY.

Under the patronage of His Majesty Leopold II., King of the Belgians, will be held in Brussels in September, 1908, under the Presidency of H. Excellency Professor Czerny, of Heidelberg.

At the first Congress, held in Brussels in September, 1905, it was decided to organise an exhibition illustrative of Cancer and its treatment for the second Congress to be held at the same place in 1908.

With a view of securing a systematised method of procedure in the construction of reports relating to specimens, some suggestions have been prepared by Dr. Jules Dollinger, professor of Clinical Surgery in the Royal University of Budapesth and president of the International Cancer Museum. Specimens for exhibition will be received by Professor Depage, General Secretary of the Society, 75, Avenue Louise, Brussels, from the 1st to the 8th September, 1908. This exhibition is not necessarily confined to members of the Society. The Congress will be so arranged as to allow exhibitors to make such demonstrations as may appear desirable by the Society during the meeting. The International Surgical Society consists of over 600 members and includes 23 national committees co-operating in various parts of the world. By the statutes of the Society the number of members is limited. The official languages of the Congress are English, French, and German. The subscription is a triennial one only of forty francs (£1 13s. 4d.) payable on election, and includes a copy of the transactions of the Congress. The members of the Society elect in Congress the National committees and other office bearers.

Application for membership should in the first instance be forwarded to the Honorary Secretary of the National Committee (Iles Britanniques) for transmission to the International Committee which meets in Brussels. The subjects selected for discussion at the Congress in 1908 and the names of the nominated reporters will be announced later on. Copies of the statutes of the Society and other information may be obtained from the Honorary Secretary, Mr. Reginald Harrison, 6, Lower Berkeley Street, Portman Square, W.

REVIEWS OF BOOKS.

FREYER ON ENLARGED PROSTATE. (*a*)

That a third edition of this work by Mr. Freyer should be required in such a short time shows in itself how useful this book has been to surgeons. The operation of suprapubic prostatectomy is very fully described, the text being assisted by numerous illustrations which make the steps of the operation very easy to follow, nor has the after treatment been neglected, for here in particular the author has spared no pains to make his methods absolutely clear to his reader, and with the large experience of over 300 prostatectomies, there is no surgeon living whose remarks can carry as much weight as those of Mr. Freyer must do on this subject. It is a pity that a little more space and attention is not given to the very interesting question of the pathology of the enlarged prostate. Mr. Freyer says: "All we know of the disease is that the enlargement of the gland is mainly, if not wholly, of an adenomatous character. Having fulfilled its purpose the gland has a tendency to run to seed, as it were, but why it does so has yet to be explained." Surely Ciechanowski's exhaustive work and his findings on the subject of hypertrophy of the prostate deserve more notice than this, not to mention the writings of a host of other pathologists. Again, in the chapter dealing with the after treatment of prostatectomies, Mr. Freyer advocates washing out the bladder solely by means of the suprapubic wound for the first week. It is, however, quite impossible to really clean out the neck of the bladder by this means, unless lotion is passed through the urethra, either direct or by means of a catheter, into the bladder and allowed to flow out through the suprapubic wound; failure to thoroughly cleanse this portion of the bladder is very likely to be followed by epidydimitis, a complication that is not mentioned; indeed the only trouble the surgeon is warned to be on the look out for after prostatectomy is the danger of secondary hæmorrhage.

That part of the book which deals with the author's claim to be the originator of the operation of total removal of the prostate by the suprapubic route might well be omitted; the proofs adduced are not convincing, and the point is one of little importance, for the whole profession cannot hesitate for a moment to give Mr. Freyer the greatest credit for demonstrating in the most wonderful way the utility of this operation. The book should be in the hands of every surgeon who does bladder work; there are many useful hints for the physician also, who will often have to treat cases of enlarged prostate gland.

HARRISON ON URETHROTOMY. (*a*)

This small work really consists of a series of lectures delivered at the London Medical Graduates College; in them the author describes the operations of internal and external urethrotomy, and a combination of these two operations, which he has often found useful, the description of these operations is not very full, the object of the book being rather to show in what type of disease or injury to the urethra urethrotomy will prove the best form of treatment. Speaking of internal urethrotomy, Mr. Harrison says this method of treatment may be indicated in cases of stricture of the urethra, and their complications, when dilation by bougies proves insufficient, and with this statement no surgeon will find any fault; but the writer then relates that out of 255 cases of stricture 182 required internal urethrotomy, the remaining 73 being treated by other measures. This surely is not the experience of most genito-urinary surgeons, treatment in many if not in most cases of stricture being very satisfactorily carried by dilating with metal bougies. Again, in performing internal urethrotomy, the author prefers one deep incision through the roof of the stricture, instead of, as is commonly done, making multiple incisions, which need, of course, not be nearly so deep; the reason for this being that the multiple incisions tend to increase the amount of cicatrix. No attempt is made to prove this somewhat doubtful statement. Hæmorrhage coming on after such an operation is lightly dealt with, it being merely stated that bleeding is rare. When more than one fatal hæmorrhage has been recorded following this form of operation, it surely deserves more attention than this.

There is, however, much of practical use in this book for the operating surgeon, many useful hints being given in the after treatment of cases. The chapter on kidney capsulotomy in particular is full of interest, brevity being its only fault.

DUTCH ON FOOD AND DIGESTION. (*a*)

In the preface the author comments on the way in which the smaller text-books on dietetics are too often written for the express purpose of promulgating some special doctrines in regard to food, and he attempts to give an unbiassed account of the principles which govern food and digestion in health and disease. The good intentions of the author are, however, marred by the loose verbiage which characterises the book. It is obvious that he has striven to produce a volume that could be appreciated by persons with no previous knowledge of medicine, chemistry and hygiene, and his efforts have resulted in the adoption of a style more suitable for a child's reading-book than for a scientific treatise.

The various articles of diet and their use and abuse are considered, and a section is devoted to dietaries in disease. The work ends with a glossary designed "to facilitate the correct interpretation of the technical terms used," which, like the remainder of the book, shows a lamentable carelessness on the part of the author in his choice of words.

THE BACTERIOLOGY AND ETIOLOGY OF ORIENTAL PLAGUE. (*b*)

It has been shown by Dr. Klein and others that a patient may exhibit symptoms simulating those of bubonic or Oriental plague without suffering from this disease, the absence of plague being shown by bacteriological examination. This renders the bacteriological evidence a very important factor in establishing the nature of the malady, and since the disease is one that calls for extreme precautionary measures to prevent a sporadic case causing an epidemic, the value of the evidence obtained from a bacteriological examination of the patient is of immense importance. From a public health standpoint the diagnosis of the disease in rats is as important as the examination of suspected human cases, owing to the terrible part these rodents play in spreading the disease. As in the case of man, Dr. Klein has shown that rats which clinically possessed manifestations of the disease, in some cases gave a negative result on bacteriological examination, and these results were confirmed by no further cases occurring. The author has shown that different species of rats vary greatly in regard to their susceptibility to the disease. The white rat is the most susceptible, the brown ship rat or brown dock rat coming next, then the black rat and a Norwegian species, and finally the least susceptible of all—our own common sewer rat.

Professor Klein cites cases of healthy rats living in the same cage or in close proximity to infected animals that did not contract the disease, which appears to show that the disease is not spread by means of fleas from one rodent to another.

The various manifestations of the disease in man and rodents, the methods and conditions of infection, the agglutination and disinfection of *bacillus pestis*, and protective inoculation, are fully considered. A considerable space is devoted to the characters of the specific organism and to microbes simulating *B. pestis*, and a chapter is devoted to the analysis of plague materials. Altogether the work is a most admirable digest of the subject of bubonic plague as recent research has revealed it. The illustrations are numerous and excellent and add greatly to the value of the book. The volume is what we should expect from a savant like Dr. Klein, who by his extensive researches and wide knowledge of the subject he deals with is well fitted to deal with and sift the clinical and experimental work performed in connection with Oriental plague.

MANUAL OF SURGERY (*a*)

It is a little over two years since we reviewed the first edition of Thomson and Miles' Surgery, and strongly recommended it to the practitioners and students. The early appearance of the second edition proves that the work has received the favour which it deserves.

The second edition has been brought thoroughly up to date and contains over fifty more illustrations and the same number of additional pages. The illustrations are even better reproduced than in the previous edition, and are particularly useful and instructive in connection with the text in the chapters dealing with fractures, dislocations, and deformities. A series of micro-photographs of the more important bacteria concerned in surgical diseases, also some very fair examples of X-ray photographs, have been added. The text has been revised, and made somewhat fuller in several particulars, and some of the more important matter has been changed from small into large print. The index contains more references.

On the whole this edition of Volume I. is a pleasing improvement on the previous one, and is well calculated to increase the usefulness of this work, and further ensure its popularity.

BREND ON MEDICAL JURISPRUDENCE. (*b*)

On taking up a small handbook of the type of this work of Mr. Brend's, we naturally ask ourselves if there is any reason why it should have appeared, and if it is anything more than a condensation of larger books on the same subject. To these questions we are satisfied that we may say "Yes." It is an original and interesting little book, not so much condensed as to be dry, and not so diffuse as to be ill-proportioned. Indeed, as a work it is well-managed, sufficient consideration being given to each subject, and modern instances and new discoveries being judiciously embodied. We may go so far as to say we know no work of its size so well adapted for students

LITERARY NOTES.

We have received as usual Willing's invaluable "Press Guide." It has now reached its thirty-fourth annual number, and for those engaged in press work it is one of the most handy and useful reference works. It contains a short, comprehensive index of all the newspapers, magazines, periodicals, guides, together with directories, journals, proceedings, and reports of societies issued in the British Isles. Besides, there is a classified list of trades, professions, sciences, religious denominations, telegraphic and reporting agencies, and a variety of other information indispensable to those who work with the pen.

⁂

THE SPIROCHÆTA PALLIDA IN DISEASES OF THE EYE.

The March number of the *Ophthalmoscope* contains a brief but important communication referring to the spirochæta pallida by the editor, Mr. Sydney Stephenson. This protozoon, it appears, has not yet been demonstrated in syphilitic lesions of the eye, except in such as have been produced artificially in the laboratory. Mr. Stephenson now announces the fact that he has found the organism in the corneal lesion of two cases of keratomalacia in syphilitic babies, seen at the North-Eastern Hospital for Children, London. Material from the ulcerations was stained by Giemsa's method after it had been smeared on the surface of cover-glasses, and a limited number of spirochætæ were found in each instance.

Weekly Summary of Medical Literature, English and Foreign.

Specially compiled for The Medical Press and Circular.

RECENT PATHOLOGICAL LITERATURE.

A New Nitro-prusside Reaction in the Urine.—According to Arnold (*Zeitschrift fur Phys. Chemie*, Bd. 49, Hft. 4 and 5), the following reaction appears in the urine about ten minutes after the injection of soup, and persists for some hours: Take 10-20 c.cm. of urine and add to it a few drops of a 4 per cent. sodium nitro-prusside solution, and 5-10 c.cm. of a 5 per cent. solution of caustic potash, there then appears in the urine a pure strong violet colour which quickly turns purple and later reddish brown. The violet solution gives a spectrum between the lines D and E, and is turned first blue and later yellow by the addition of acetic acid. The body which gives the reaction is destroyed by heating with mineral acids, but is not affected by heating the untreated urine. It is non-volatile, but can be extracted by acetic ether and by chloroform. It does not appear to be of endogenous origin, and the reaction that it gives differs from that of other known urinary contents.

M.

The Blood in Pernicious Anæmia. — Emerson analyses the series of blood counts made from 89 cases of pernicious anæmia in the Johns Hopkins Hospital during the last few years (*Johns Hopkins Hosp. Bulletin*, February, 1907). His analysis deals both with the red cell and white cell changes. As regards the latter, he is able to draw the following conclusions: (1) An absolute lymphocytosis, meaning by that term the presence of over 2,000 lymphocytes per cm., is occasionally met with, and appears to be of evil significance. (2) A relative lymphocytosis is very common, being found in 61 out of 69 cases. (3) Total disappearance of eosinophile cells is a bad sign, but on the other hand an increase in their number does not always mean that the prognosis is good. (4) Myelocytes occur more constantly and in greater numbers in pernicious anæmia than in any other disease, except leukæmia. (5) As a rule the total count of white cells runs parallel with that of the red. As regards red cells and the hæmoglobin content, it was found that the hæmo globin index was almost always above unity. The symptoms complained of by the different patients on admission varied with the blood count; thus those who had under 1,000,000 per cm. complained of dyspnœa and weakness; those with counts from one to two millions had gastro-intestinal symptoms; while nervous symptoms predominated amongst those who sought admission with counts over two millions. In very few cases was it possible to get the number above four millions, even by prolonged treatment, and it was noticed that the count tended to vary in a wave-like manner, a period of gradual rise being succeeded by one of gradual fall. Sometimes the rise in number coincided with a general increase in the symptoms complained of, though as a rule the reverse was the case. Probably in the former type the rise in number is due to concentration of the plasma and is not a genuine increase. The counts at death varied considerably according as death was due to some terminal infection, or to simple weakness and anæmia. M.

Primary Tuberculosis of the Kidney. — Curtis and Carlier (*Arch. de Med. Experim.*, 1905, p. 439) call attention to the occurrence of primary renal tuberculosis, as distinct from the variety that occurs by spread up the ureter. They describe a kidney which they believe to be of the primary type removed by operation from a man, æt. 27. The organ was very much enlarged and was composed of numerous cysts, resembling those found in congenital cystic tumours. The bacillary virus had given rise to interstitial, epithelial, and cystic changes. Clinically, the long duration of the affection was remarkable. After operation, which was performed some years ago, the patient has continued to enjoy excellent health, a fact which is in favour of the condition being primary. The authors believe that it arose by way of the blood stream, and that the first change took place in the cortex. M.

The Relationship of Gonococci to Meningococci.—Recent investigations have shown that precipitin reactions may be employed as a means of grouping different varieties of bacteria into genera. For example, the same immune serum may prove effective against different bacteria, and may also give a precipitate with the bacterial products of different members of the same genus of bacterium. Similarly agglutination is capable of being used to distinguish genera. Tupnik has attempted to investigate the relation of gonococci to meningococci by the above indicated methods (*Berlin Klin. Woch.*, 1906, No. 53). In several cases of cerebro-spinal meningitis he isolated a coccus resembling that of Weichselbaum, and indistinguishable in growth on the ordinary media from gonococci. He then proved that gonococci and meningococci produce similar agglutinins precipitins, toxines, and anti-toxines, and in consequence holds that they belong to the same genus, although they differ in kind by producing different pathological effects in the animal body. The same genus includes amongst its members the diplococcus conjunctivitidis, and most probably Pfeiffer's diplococcus catarrhalis as proved by the same tests. M.

Ovarian Influence upon the Uterus.—Marshall and Jolly report some experiments which they have made in connection with the above (*Edin. Med. Journal*, March, 1907). The ovaries were removed by anterior incision from 33 rats, and the animals were killed at periods varying from two and a half to eight months after the operation. On examining the uterus it was found that that organ differed from the normal as follows: It was usually small and atrophic, the mucosa was thin and poor in cells, the mucosal glands small, and the connective tissue was increased in amount. In those cases where traces of the ovary had been left behind no atrophic appearances were found. The authors then attempted transplantation of ovarian tissue and succeeded in eight cases in transplanting the ovary from its normal site to another situation in the same animal. Two cases of heteroplastic transplantation also proved successful. The appearance of the uterus was later found to bear a relation to the microscopic appearances of the graft. If the graft had failed there were signs of uterine degeneration, but if it had taken the uterus was normal. The authors conclude that the uterus is dependent for its proper nutrition on some internal secretion of the ovary.

M.

The Conduction of Sensory Impressions in the Spinal Cord.—Simpson and Herring make (*British Medical Journal*, December 21st, 1906) an important contribution to our knowledge of the paths taken by sensory impressions in their transmission to the brain. They note the great variety of opinions held both as to the tracts of the cord in which the impressions travel, and as to the question whether crossing takes place in the cord or at a higher level. The authors' experiments were performed on cats, the cord being exposed and a lesion produced by the galvano-cautery. The animals were then kept for three or four weeks, their sensibility being fully tested. The lesion was exactly located by a post-mortem examination. The following conclusions were arrived at: (1) The integrity of the grey matter is not essential to the conduction of impressions of pain; in several cases where the animals responded at once to painful stimuli, the grey matter was found to be entirely destroyed. (2) Total destruction of both posterior columns does not affect sensibility to pain. (3) Impressions of pain travel both crossed and uncrossed, principally the former. Lesions involving the whole transverse section of the cord, with the exception of the antero-lateral column on one side and a thin zone of grey matter adjacent to it, did not abolish the sense of pain on either side, but the response was more ready on the side of the lesion than on the sound side. (4) It is probable that impressions of cold travel by the lateral columns, and that the conduction is both crossed and uncrossed. (5) The only lesion which abolished the passage of all forms of sensation was a complete transverse section. R.

The Spirochæte in Congenital Syphilis.—Schultz (*Journal of Medical Research*, December, 1906) reports very fully the microscopic findings in two cases of congenital syphilis. They bear out the statements of Levaditi, Herxbenner, Gierke, and others. The characteristic organism was found in practically all the organs of the body—liver, spleen, kidneys, adrenals, thymus, pancreas, heart. It was found, also, but very scantily, in the placenta and umbilical cord. The organism appears to be usually intracellular, and, therefore, may not be demonstrable in smears, even where very plentiful. In the organs it is situated chiefly in the proliferating connective tissue. It is also found in considerable numbers in the walls of the arteries. In one of the cases a gumma was present in the lung. No spirochætes were found in the necrotic mass, a few were found in the fibrous capsule, and many in the infiltrated tissue around. This observation supports the statement of Metchnikoff and Roux that gummata are infective, but that large quantities of material are necessary for successful inoculation. The paper is illustrated by some fair micro-photographs. R.

Functional Albuminuria in Athletes.—Collier publishes (*British Medical Journal*, January 5th, 1907) a note on functional albuminuria in athletes, which shows both that the condition is more common than is generally believed, and that the albumin is often considerable in amount. He has examined the urine of men who have rowed or run in severe races. Of specimens of urine obtained from 156 apparently healthy young men training for the "Torpids," 81 showed by the cold nitric acid test a very definite amount of albumin, albumin being present in smaller quantity in 24 other cases. These specimens came from men after moderate exercise. When specimens were obtained after racing, the number of those containing very definite amounts of albumin was strikingly increased. The urines of the Oxford crew after the last Oxford and Cambridge race were examined, and all of them found to contain albumin, 50 per cent. in large quantities. The urine of men or boys who had run races was in every case but one of some 50 examined found to contain albumin. Collier believes the condition of little bearing upon health, and thinks functional albuminuria should not be given such weight in examinations for life assurance. R.

Lesions Due to Trichina Spiralis.—Frothingham (*Journal of Medical Research*, December, 1906) publishes a careful account of the examination of the body of a patient who died while suffering from trichina. He concludes: (1) The finding of trichina embryos in the mesenteric lymph nodes and in liver sinusoids, shows that they enter by the lymph stream and are distributed by the circulating blood. This is confirmed by the discovery of the presence of trichina embryos in the hæmorrhagic areas in the lungs of man, a fact already observed in the case of animals. (2) The embryos may escape from the vessels in the liver, pancreas, brain, and heart (and possibly other organs), causing local destruction of the tissue. (3) The capsule of the encysted trichina is formed of connective tissue which surrounds the whole of the invaded fibre. R.

The Tonsil as a Defence.—Brown (*Medical Record*, March 2, 1907) argues in favour of the view that the tonsil is a wall of defence towards, rather than a portal of entry for, infective organisms. As is well known, the tonsils have a rich blood supply, and they are covered superficially with a close mesh-work of lymphatics. Brown states that there is a constant exudation of leucocytes through the tonsillar crypts on to the mucous membrane, this exudation being markedly increased in the presence of virulent infective agents, Adopting the correct view of inflammation as a defensive measure, Brown argues that the frequent occurrence of tonsillitis is in fact an illustration of the greater defensive power of the tonsil than of other parts of the mouth. In this suggestion he assumes that germs may enter other buccal surfaces without stimulating the reaction known as inflammation. There is much in favour of the view that the tonsils in the mouth, like the Peyer's patches in the intestine, are less, rather than more, pervious to bacteria than the neighbouring surfaces. Anything we know of lymphoid tissue goes to prove that in every situation it has defensive functions, and it is unlikely that the tonsils and Peyer's patches should be exceptional. R.

Internal Diverticula of the Intestine.—Skirving (*British Medical Journal*, February 2, 1907) reports a rare and curious condition of the small intestine encountered while operating for hernia. Scattered over a distance of nine inches there were six hollow finger-like processes projecting obliquely into the lumen of the gut. All ended blindly, and were apparently localised invaginations of the whole thickness of the wall of the gut. The shortest was one inch in length, the longest two inches. All attempts at reducing one of them failed. Skirving is unable to suggest any explanation of the condition. R.

Inquest on a Medical Man.

Mr. Luxmoore Drew concluded his inquest at Hammersmith, on Saturday, on "Jack S. Egerton Layton," aged 43 years, a ship's doctor, who died from prussic acid poisoning at Sinclair Road, West Kensington. The deceased came from Australia in December last as surgeon on the SS. "Wakool," and stayed at a boarding-house at Sinclair Road. He afterwards signed a contract to return to Australia on February 5th as surgeon of the "Narrung," belonging to the same company. On February 14th, the deceased was found dead in bed, with an empty bottle by his side, and Dr. Crawford Thomson attributed death to a large dose of prussic acid. The police reported that inquiries had been made at the General Medical Council's registration offices, the Colonial Offices, the Crown Agents for the Colonies, at Ealing, Kingstown (Ireland), Guy's Hospital, and the London Hospital and other places, but nothing could be found to lead to the deceased's identification. Some of his books were marked "W. A. Best," but that was the name of a doctor who died in Sydney, N.S.W., in 1905. Many persons had tried to identify the deceased, including a countess living at Eaton Place. After other evidence the coroner said the deceased's whole life seemed to be a mystery which it appeared impossible to clear up. The jury returned a verdict of "Suicide whilst of unsound mind."

MEDICAL NEWS IN BRIEF.

The Irish Medical Schools and Graduates Association.

THE thirtieth annual meeting of the above association was held on Saturday last, March 16th, at the Hotel Cecil, when Dr. E. Irwin Scott, having completed his year of office, resigned the Presidential Chair to Sir John William Moore, of Dublin. The Vice-Presidents elected for the ensuing year were: Sir James Dick, K.C.B., Sir William Whitla, Drs. H. Macnaughton Jones, E. Irwin Scott. Dr. J. H. Swanton continues Chairman of Council and Dr. Kenneth Frazer Vice-Chairman. Dr. M. J. Bulger was re-elected Hon. Treasurer and Dr. T. Hobbs Crampton, Mr. E. Canny Ryall, and Dr. W. Douglas continue as Hon. Secretaries.

The following were elected to fill the vacancies in the Council: Drs. W. H. Bourke, Campbell Boyd, Morgan Dockrell, J. G. Fitzgerald, J. Finch Haines, J. A. Macdonald, J. Moorhead, and R. Jocelyn Swan. The other members of Council being Drs. W. Barter, G. W. Dawson, T. Beech Johnson, J. J. Macan, Alex. McDonnell, L. Strong McManus, Moyle O'Connor, W. Booth Pearsall, Redmond Roche, James Stewart, Dr. J. A. Preston,, and Surgeon-Lieutenant-Colonel R. Ross Brown, J.P. were appointed Hon. Auditors.

The Council reported the continued professional and social success of the Association, which had enabled many old friendships to be renewed and maintained, also the satisfactory financial position of the Association. The Council had pleasure in stating that the Arnott Memorial Medal had been awarded to Sir Almroth Wright, F.R.S., for his valuable contributions to medical science. Also that they had received with great regret the resignation of Dr. James Stewart, who had been for nearly twenty-two years Hon. Provincial Secretary, and in that position had by his zeal and energy done much to promote the welfare of the Association.

Mr. W. Booth Pearsall, Member of the Council, presented to the Association a presidential badge in enamel work, designed and made by himself. The badge is in the form of a small shield, having a border with the motto of the Association. This encloses a design in green enamel with shamrocks surrounded by blue to represent the sea. In the centre, on a white ground, is displayed the red cross of St. Patrick. The badge was much appreciated not only for its own value, but as being the work of one of the members.

The St. Patrick's Festival Dinner was held after the meeting, the principal guests being the Rt. Hon. Sir Albert Henry Hime, K.C.M.G., Sir Almroth E. Wright, F.R.S., and Admiral of the Fleet Sir E. Seymour.

Tropical Medicine and Hygiene.

THE new Society of Tropical Medicine and Hygiene met at the Royal College of Physicians on March 15th for the purpose of drawing up rules. Sir Patrick Manson presided, and a sub-committee to make the necessary arrangements was formed of the Chairman, Colonel Melville, Dr. Sandwith, Dr. Carnegie Brown, Professor Ronald Ross (Liverpool School of Tropical Medicine), Dr. G. C. Low, and Mr. Cantlie. To these gentlemen the following were added in order to constitute a general committee: Professor Nuttall (Cambridge), Dr. William Hartigan, Dr. Leopold G. Hill, Dr. Charles F. Harford, Lieutenant-Colonel Andrew Duncan, Lieutenant-Colonel Oswald Baker, Lieutenant-Colonel G. M. Giles, Dr. A. T. Stanton, and Dr. Sambun. At yesterday's meeting the chair was taken by Dr. Sandwith, and among those present were Dr. John Anderson, Professor W. R. Smith, Dr. T. P. Beddoes, and Professor Haffkine, the discoverer of a prophylactic for Indian plague. The Chairman explained that the promoters of the society hoped to see it become universal, embracing every man and woman interested in tropical medicine and hygiene. Another gentleman remarked that nine-tenths of the members would probably live abroad, and it may be added that the purpose of the association is the mutual instruction and support of the members.

The University Question in Ireland.

Two important series of resolutions dealing withthe University question have been adopted by various bodies within the past week. The first of these was adopted by the Higher Education Committee of the Presbyterian Church. The series is too lengthy for us to publish *in extenso*, but their general purport is to approve in the main of Mr. Bryce's scheme with certain provisos. The present Chief Secretary for Ireland is an ingenious and resourceful man, and if he can combine these provisos with the provisos which will be and no doubt are being insisted upon by the Roman Catholic Hierarchy, he will have performed a task that few other men would attempt even to tackle. His effort is bound to be of the greatest interest to all those interested in the social and political life of Ireland. The second series of resolutions also comes from Belfast, and has been adopted by the Council of the Royal University Graduates Association. These resolutions condemn Mr. Bryce's scheme lock, stock, and barrel, and wind up by directing attention to "the extraordinary conduct of the thirteen members of the Senate who withdrew their opposition to a scheme which four months ago they had declared to be disastrous to the interests of education and gravely injurious to the welfare of the country." In addition to these resolutions an important "statement" has been issued by the Dublin University Defence Committee.

Numerous meetings have also been held both by supporters and opponents of the present scheme. On Thursday a public meeting was held at the Mansion House, Dublin, under the Presidency of Professor Magennis, F.R.U.I., in support of the scheme, and it was addressed by, amongst others, Mr. McArdle, F.R.C.S.; Dr. Pye, Queen's College, Galway; and Dr. Connor Maguire. On the other hand, a meeting of the resident members of the University has been held at Oxford at which resolutions protesting against interference with Trinity College were adopted. Meetings of a similar nature were also held at Bristol and Manchester. On Friday, March 22, a meeting of the graduates of the University will be held in Trinity College.

Royal College of Surgeons.

Meeting of the Council.—An ordinary meeting of the Council of the Royal College of Surgeons was held at the College last Thursday, Mr. Henry Morris, President, being in the chair. The following members of the College, having passed the required examinations and conformed to the bye-laws, were admitted Fellows of the College: Mr. Lionel Edward Close Norbury, M.B., B.S., L.R.C.P.Lond., of St. Thomas's Hospital; and Mr. Gerald Charles Frederick Robinson, L.R.C.P. Lond., of Guy's Hospital. Mr. Henry Orton Howitt, of McGill University, Canada, and London Hospital, was admitted a member of the college, and a diploma of the licence in dental surgery was issued to Mr. Thornton John Barnett, of Charing Cross and Royal Dental Hospitals.

Appointments and Awards.—Mr. J. Ernest Lane, Surgeon to St. Mary's Hospital, was admitted a member of the Court of Examiners. Mr. J. Rickman Godlee, Vice-President, was appointed Bradshaw Lecturer for the ensuing collegiate year. Mr. A.

Pearce Gould was re-appointed one of the two representatives of the college upon the senate of the University of London for the next four years. Mr. J. Ward Cousins was re-elected the representative of the College on the Central Midwives' Board for the ensuing year. The President reported that the Sir Gilbert Blane's medals had been awarded to Staff-Surgeon James William Wilcocks Stanton, of H.M.S. "Suffolk," and Surgeon Bernard Ley, of H.M.S. "Algerine."

Women's Diplomas.—The Secretary submitted a list of 2,594 signatures in support of the petition to the council in favour of the admission of women to the examinations of the college, sent from the London School of Medicine for Women. The list contains no signatures of medical women, or of lay persons, other than those officially connected with the School of Medicine and the Royal Free Hospital.

A National Anthropometric Survey.—A letter was read from Dr. Arthur Keith reporting his attendance as the representative of the college, with the deputation to the Prime Minister to urge the importance of a national anthropometric survey, and giving a short account of the grounds upon which the importance of the survey was urged and of the reply of the Prime Minister.

Festival Dinner of the Hospital for the Paralysed and Epileptic.

A FESTIVAL dinner in aid of the funds of the National Hospital for the Paralysed and Epileptic and of the Nervous Diseases Research Fund of that institution was held on March 11th, at the Hotel Metropole. Sir Edgar Speyer, the treasurer of the institution, presided, and in proposing "Success to the Hospital" said the hospital did not pretend to deal with chronic cases, but it dealt with many cases which a few years ago were considered to be incurable. He appealed to them on behalf both of the cure and of the investigation of the terrible diseases with which the hospital dealt, the consequences of which were worse than any other class of diseases. Owing to the failure in receipts of legacies, which in 1906 fell very much below the average, the income had not balanced the expenditure, and the institution had had to borrow from the bankers. It was urgently necessary to repay the £4,000 borrowed and to maintain the institution at its present level. At the present time 100 patients were awaiting admittance. Mr. Macmillan, in responding said that the committee of the hospital had combined the *maximum* of efficiency with the most rigid economy. Sir Victor Horsley, in proposing "Success to the Nervous Diseases Research Fund," said the hospital had not only founded a clinical laboratory, but it had also organised a fund for research into nervous diseases, which would have an influence in all countries. Donations and subscriptions were announced amounting to over £2,500, and it was stated that unless the donors had otherwise stipulated, five-sixths of the amount subscribed would be applied to the hospital fund, and one-sixth to the research fund.

Invalid Prisoners.

The following explanatory memorandum is prefixed to the Released Persons (Poor Law Relief) Bill [100], brought in by Mr. Herbert Samuel and backed by the Home Secretary:—

The object of this Bill is to meet a difficulty which arises when a person who is due for discharge from a prison is destitute and in such an infirm state of health as to require immediate Poor Law relief.

In such a case it is the duty of the governor of the prison to see that the invalid shall receive proper care on his discharge. Where the place of settlement can be ascertained, an order for his admission to the workhouse of the union can be applied for, but if, as often happens, the place of settlement cannot be ascertained or is disputed, the only course open is to take the invalid to the workhouse of the union in which the prison is situated and apply for his admission as a case of urgent necessity. In the case of a large prison from which many destitute and infirm prisoners may have to be discharged this course imposes a liability on the ratepayers of the union in which the prison is situated.

To remedy the evil this Bill (following the precedent of the Criminal Lunatic Act, 1884) proposes to throw the *prima facie* liability for the relief of an invalid prisoner, whose place of settlement is unknown, on the union in which he ordinarily resided at the time he committed the offence for which he was sent to prison, or, if that cannot be ascertained, on the union where the offence was committed. The guardians of the union where he is sent in the first instance will be able afterwards, if they see fit, to take steps for his removal to his place of settlement.

Clauses 2 and 3 of the Bill extend the principle to persons discharged from reformatory and industrial schools and inebriate reformatories, as the same difficulty has been experienced in these institutions.

Death under Chloroform.

AN inquest was held at the Preston Infirmary, on March 13th, concerning the death of Emma Gittins, wife of a boilermaker. Deceased's husband said that for six weeks his wife had been suffering from pains in the bowels. On Saturday she was removed to the Infirmary on medical advice.

The medical eveidence showed that an operation was necessary to save life. The anæsthetic had been skilfully administered, when the patient suddenly collapsed. Everything possible was done to resuscitate her, but without avail. Had the operation not been performed, the patient would probably have died in forty-eight hours, as the inflammation was rapidly extending. All known methods of restoration were applied for threequarters of an hour.

The Coroner said the jury would agree that every consideration had been given to the case. Doctors Sellers, Dunn, and Collison, and the staff of the Infirmary had consulted, and decided that it was advisable the operation should take place. They believed they might be able to save the patient's life. Everything possible seemed to have been done to restore her. The Foreman: I think they have done everything possible. A juror expressed the belief that most extraordinary care had been exercised. A verdict that "Death was due to misadventure." was returned.

More Litigation in Dental Partnership Case.

THE final action of Hill *v.* Clifford was heard before Mr. Justice Warrington in the Chancery Division in which the plaintiff claimed a declaration that a notice he had given for the dissolution of a dental partnership was valid and binding upon the defendants, Isidore and Ruben Edmund Clifford. It appeared that the defendants were members and managers of the American Dental Institute, which carried on a dental business at Liverpool and London, and, on the ground that the Institute had been guilty of "infamous" or disgraceful, conduct in a professional respect, the names of the defendants and others were struck off the dental register by the General Medical Council. This, the plaintiff contended, entitled him, under the partnership articles, to dissolve his partnership with the defendants. In two similar cases to which Isidore Clifford was a party his lordship had held that the finding of the Medical Council was not binding on the court, and upon the facts before him professional misconduct had not been proved. Mr. Norton, K.C., who, with Mr. Ward Coleridge, represented the plaintiff, contended that this case differed from the previous inasmuch as he should produce evidence that before the Medical Council, counsel for the defendants admitted professional misconduct. Mr. H. Terrell, K.C., with whom were Mr. Houston and Mr. Drake, was not called upon. His Lordship held that the case was governed by the action of Clifford *v.* Timms and Clifford *v.* Phillips, and therefore there must be judgment for the defendants, with costs.

NOTICES TO CORRESPONDENTS, &c.

☞ **CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

M.O.H.—You can get all information *re* the Gordon Memorial College at Khartoum from the Principal, Mr. James Currie. The laboratories are at present in the College, but an appeal has been made for a separate building.

OBSTETRICIAN.—The question of fees for medical men called in by midwives still remains before the Central Midwives' Board. No fewer than six midwives were censured at the last meeting for not having called in a doctor, but the usual indifference was shown to the fact that no fee would have been forthcoming for his attendance.

M.R.C.S.—The Paper you are doubtless thinking of is in the "Journal of Abnormal Psychology," which came out last April, and is called "The Pathogenesis of Some Impulsions," by Dr. Pierre Janet.

YOUR PORTRAIT FOR NOTHING.

THE enterprise of the Leibig Extract of Meat Company is decidedly progressive. They now announce that in order to make their preparation, "Oxo," still more widely recognised by the medical profession they will give away, free of charge, enlargements of purchaser's own photographs. These are mounted to measure 23 by 19 inches, and are said to be beautiful reproductions. To obtain one of them, the purchaser has to save the coupons fixed over the capsules of "Oxo" bottles until 21s. worth has been collected, when they should be sent, together with the photograph to be enlarged, to "Oxo Portrait Department, 4 Lloyd's Avenue, London, E.C." In exchange for additional coupons, to the value of 21s., applicants' pictures can be framed in oak, with gold slip.

PATER.—We have not the official figures before us for the past year, but we understand there has been a considerable falling off in the number qualified compared with previous years.

M.D. (Nottingham).—We cannot take the responsibility of publishing the terrible charges you make without authoritative references to the operations you describe. If these experiments were done without anæsthetics, they should be substantiated by chapter and verse and brought before the notice of the Royal Commission now sitting. If done under anæsthetics, of course, no pain would be felt.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MARCH 20th.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m.: Lecture:—Prof. C. F. Beadles: The Cerebral Arteries (illustrated by specimens, drawings, and lantern slides).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. J. Cunning: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. J. Poland: The Use and Abuse of Skiagraphy in Fractures and Dislocations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—Cliniques:—2.30 p.m.: Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Out-patient (Dr. Whipham).

THURSDAY, MARCH 21st.

NEUROLOGICAL SOCIETY OF THE UNITED KINGDOM (11 Chandos Street, Cavendish Square, W.).—9 p.m.: Clinical Meeting. Patients in attendance at 8 p.m.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. H. J. Curtis: Liver Abscesses, their Etiology, Symptoms, and Treatment.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques: Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson). 3 p.m.: Medical In-patient (Dr. Chappel). 4.30 p.m.: Demonstration:—Dr. G. B. Price: Clinical Examination of the Urine.

FRIDAY, MARCH 22nd.

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8 p.m.: Clinical Evening for the Exhibition of Cases followed by Discussion. Patients in attendance from 8 to 9 p.m.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m.: Lecture:—Prof. C. F. Beadles: The Cerebral Arteries (illustrated by specimens, drawings, and lantern slides).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Dr. H. Tilley: Clinique. (Throat.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—9.30 a.m.: Clinique. Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. Leslie).

MONDAY, MARCH 25th.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (20 Hanover Square, W.).—Casual Communication:—Dr. J. W. Pare on "A New Local Anæsthetic." Short Paper: Mr. J. G. Turner on "Hereditary Hypoplasia of Enamel." Dr. Charles Stewart will exhibit and describe some Dental Specimens from the Hunterian Museum.

TUESDAY, MARCH 26th.

THERAPEUTICAL SOCIETY (Apothecaries' Hall, Blackfriars, E.C.).—4.30 p.m.: Papers:—Dr. W. E. Dixon on "How Drugs Produce their Effects" and Dr. Nestor Tirard: "Opium in the Treatment of Pneumonia."

Vacancies.

Leeds Public Dispensary.—Two Junior Resident Medical Officers. Salary £100 per annum, with board and lodging. Applications to the Secretary of the Faculty, Public Dispensary, Leeds.

Whitehaven and West Cumberland Infirmary.—Resident House Surgeon. Salary £120 a year, with board and lodging. Applications to W. H. Sands, Secretary, Whitehaven.

The General Infirmary at Leeds.—Resident Casualty Officer. Salary £125 per annum, with board, lodging, and washing. Applications to the Secretary to the Faculty, General Infirmary, Leeds.

Manchester, Township of.—Assistant Medical Officer. Salary £110 per annum, with furnished apartments, fire, light, washing, and attendance. Applications to James Macdonald, Clerk to the Guardians, Poor-Law Offices, New Bridge Street, Manchester.

Royal South Hants and Southampton Hospital.—House Surgeon. Salary £100 per annum, with rooms, board, and washing. Applications to T. A. Fisher Hall, Secretary.

Asylums' Service of the Metropolitan Asylums Board.—Male Third Assistant Medical Officer. Salary £150 per annum, with rations, board, lodging, attendance, and washing. Application of the Board, Embankment, London, E.C.

Durham University, College of Medicine, Newcastle-upon-Tyne.—Head Laboratory Attendant in the Bacteriological Department. Applications to the Secretary. (See advt.).

Appointments.

BENNETT, H. G., M.R.C.S., L.R.C.P.Lond., House Physician to Out-patients at St Thomas's Hospital.

BRISTOW, W R., M.R.C.S., L.R.C.P.Lond., to the Throat Department at St. Thomas's Hospital.

BURGESS, A. S., M.R.C.S., L.R.C.P.Lond., Junior Ophthalmic House Surgeon at St. Thomas's Hospital.

BUTLER, G. G., M.R.C.S., L.R.C.P.Lond., House Physician to Out-patients at St. Thomas's Hospital.

CARLETON, H. H., M.B., B.Ch. Oxon., to the Children's Surgical Department at St. Thomas's Hospital.

CASSIDY, M. A., M.B., B.C. Cantab., Resident House Physician at St. Thomas's Hospital.

DREW, J. H., M.B., B.S.Lond., Senior Casualty Officer to St. Thomas's Hospital.

DUNKLEY, E. V., M.B., B.S.Lond., Resident House Physician at St. Thomas's Hospital.

FIRTH, A. C. D., M.R.C.S., L.R.C.P.Lond., Junior Obstetric House Physician at St. Thomas's Hospital.

GAMLEN, R L., M.R.C.S., L.R.C.P., Resident House Surgeon at St. Thomas's Hospital.

GARDEN, W. SIM, M.B., B.Ch. Aberd., Second Assistant Medical Officer at Menston Asylum, near Leeds.

GRIMWADE, S. W., M.R.C.S., L.R.C.P.Lond., to the Children's Surgical Department at St. Thomas's Hospital.

HAY, K. R., M.B.Camb., M.R.C.S., L.R.C.P.Lond., Honorary Physician to the Westminster General Dispensary.

HOWITT, A. B., M.B., B.C. Cantab., Junior Casualty Officer to St. Thomas's Hospital.

HUGGINS, G. M., M.R.C.S., L.R.C.P.Lond., House Surgeon to Out-patients at St. Thomas's Hospital.

HURLEY, JAMES, L.R.C.P., L.R.C.S.Edin., L.F.P.S Glasg., Medical Officer for the Magor District by the Newport (Mon.) Board of Guardians.

HUSTLER, G. H., M.B., Ch.B.Leeds, Medical Officer to Hospital Ship (Royal National Mission to Deep Sea Fishermen.)

ILES, A. J. H., M.R.C.S., L.R.C.P.Lond., to the Electrical and X-Ray Department at St. Thomas's Hospital.

LINDSAY, D. LAUDER. L.R.C.P. and S.Edin., L.F.P.S.Glasg., L.M. Surgeon to the Police at Aldershot, Hants.

MACDONALD, S. G., M.B., B.C. Cantab., Resident House Surgeon at St. Thomas's Hospital.

NEILD, F. M., M.R.C.S., L.R.C.P.Lond., House Surgeon to Out-patients at St. Thomas's Hospital.

NIGHTINGALE, H. J., M.R.C.S., L.R.C.P.Lond., House Surgeon to Out-patients at St. Thomas's Hospital.

PAGE, C. M., M.B., B.S.Lond., Resident House Surgeon at St. Thomas's Hospital.

PHILPOTT, H. A., M.R.C.S., L.R.C.P.Lond., Resident House Physician at St. Thomas's Hospital.

POLLOCK, W. B. INGLIS, M.D.Glasg., Consulting Ophthalmic Surgeon to the Ayr County Hospital.

READ, H. W., M.R.C.S., L.R.C.P.Lond., to the Dental Department at St. Thomas's Hospital.

RODGERS, J. W., L.R.C.P. and S.Irel., Certifying Surgeon under the Factory and Workshop Act for the Dorking District of the county of Surrey.

SANKEY, W. O., M.B., B.S.Lond., Resident House Physician at St. Thomas's Hospital.

SCOTT, H. M., L.R.C.P. and S.Irel., Certifying Surgeon under the Factory and Workshop Act for the Enniscrone District of the county of Sligo.

Marriage.

MITCHELL—THOMAS.—On March 9th, at the Parish Church, Weybridge, Annie Gladys, eldest daughter of J. Edwin Thomas, Esq., Adelaide, South Australia, to Charles Martin Mitchell, M.R.C.S. Eng., L.R.C.P.Lond., of Oakfield, Lydney, Glos.

Deaths.

FINCH.—On March 16th, at 2, Western Terrace, St. Marychurch Torquay, Thomas Finch, M.B.

GREENWAY.—On March 12th, at Llandrindod Wells, Alfred Griffith, Greenway, M.D., M.Ch., second son of the late William Partridge Greenway, of Moseley Court, Bushbury.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIV. WEDNESDAY, MARCH 27, 1907. No. 13

NOTES AND COMMENTS.

The Thaw Trial Still.

THE interminable Thaw case drags on from day to day and week to week, and even the American quidnuncs have lost interest in it. So, too, have the British. All possible moral garbage and pathological sludge having been duly displayed to the eye of the world, the actual result of the trial seems little further to concern them. As a matter of fact, the medico-legal, and, we believe, the sociological, importance of the case increases daily. This trial, owing to the wealth of the Thaw family, is a concrete *reductio ad absurdum* of the legal theories of criminal responsibility, and if its lessons are taken to heart there is no saying what result it may not have on the attitude of civilised countries towards crime. Thaw has shown himself, and been shown by the expert witnesses, to be a rather under-average man of dissipated tastes. Being well-supplied with money and, like Dolon, the victim of an adoring female household, these deficiencies were in no way corrected and counteracted in his upbringing, and he had a free rein to indulge in the pursuits he desired. There are, of course, hundreds such in London, New York, and every large city, and they do not attract much attention; indeed, except in a few cases, they eventually become decent citizens and sit in the House of Lords or on the county bench. By force of circumstances, however, Thaw found himself involved with White, and nursed his grudge till a good opportunity of killing him presented itself. When it occurred, with considerable deliberation, Thaw produced a revolver and shot him. In all, a painfully commonplace crime, such as happens in its scores in every country in every age.

Its Real Significance.

Now, judged by the ordinary criteria, there is no doubt whatever that Thaw knew he was doing what was wrong in the eyes of society, and also, no doubt, that he was possessed of sufficient control to have prevented himself from committing the murder had the circumstances proved inauspicious. He was under no delusions—in the technical sense—about White; for whether White was the sensual monster he was supposed to be or not, the evidence on which Thaw rested his belief was sufficient and reasonable. On the theory of poetic justice, the crime was justifiable, and on poetical grounds, appeal is certain to be made to the sentiment of America if all other pleas fail. As the American law courts deal in prose—and that very plentifully—the plea for Thaw escaping the penalty of his action is that of insanity. After many days of expert evidence, the Court has practically decided that it is incapable of judging on this point. Medical men have given evidence on both sides, the gist of which, stated in plain language, is that crime being abnormal is itself evidence of mental abnormality, and that the question is really one for society. Does it wish judicially to execute abnormal people? The Thaw legal expenses will not be wasted if they can get an answer to that point, which is really what civilisation has long been working up to without realising it. Thaw is abnormal, but probably no murderer was less abnormal than he.

Mrs. Osler's Death.

THE death of the venerable mother of Professor Osler will call forth general sympathy from the medical profession in this country. Quite recently we had the pleasure of commenting on the rejoicings that accompanied that lady's hundred-and-first birthday, when children, grandchildren, and great-grandchildren were assembled from all over the world to congratulate their common parent on her extraordinary vitality. And now she has passed away. Mrs. Osler was remarkable for more than being the mother of her distinguished son; she was a woman of great industry and accomplishments, and to the end of her long life took a keen personal interest in all matters of pith and moment. May her longevity prove as hereditary as her good qualities!

"Doctor's" Crime.

IF registration is to confer on medical men a mark whereby they may be known, and if no man can use a title implying that he is registered when he is not, it ought to be possible to prevent the terms physician, surgeon, doctor, and medical practitioner, being applied to charlatans and unqualified practitioners. For instance, last week in the *Daily Telegraph* there was reported from the Central Criminal Court the case of a Caleb Charles Whitefoord, who was indicted on a charge of performing illegal operations on women, and eventually found guilty and sentenced. Now this man was struck off the *Medical Register* years ago for this same offence, and yet we find the report headed "Doctor Sentenced," and the prisoner himself described as "medical practitioner." Naturally, all the people who read the *Daily Telegraph* have come to the conclusion that "another doctor has been found out," and very likely "they are all the same, only they are not all caught." The profession has to bear a heavy enough burden without being saddled with injustices of this description, and we think it is time that leading dailies should have learned to distinguish between qualified registered medical men engaged in legitimate practice, and unregistered practitioners who dabble in fraud, crime, and conspiracy. The distinction demands as little perspicacity as is required to distinguish between a jeweller who keeps a shop and a thief who robs it.

A Union of Hearts. The fissiparous character of anti-vivisectionist societies is a phenomenon of sufficient significance to deserve some study; it is extraordinary how toilers in the same vineyard cannot manage better to agree among themselves, but the fact is sufficiently witnessed to by the number of societies that now appeal for support. A more than ordinarily diverting instance of this dissension was made public last week in an action tried at the Lancashire Chancery Court. It appears that Miss Frances Power Cobbe left a legacy of £5,000 to the British Union for the Suppression of Vivisection, the organisation with which she was connected for many years, and which naturally looked to her for support. However, when the estate was wound up and money was ready for handing over, lo! no one could tell who was competent to receive it. It appears that the union, after the master-spirit of Miss Cobbe was withdrawn and before the money was ready, had divided into two sections, and no agreement could be patched up as to who was to get the spoil. According to the report in the *Manchester Guardian*, there was a great array of counsel, all sorts of interests being represented. There was evidently a fine fighting spirit abroad, as the Vice-Chancellor was anxious to make a settlement lest all the money should be spent in litigation. But, as he told the minority to watch the majority, and to take proceedings in Court if they thought the money was not properly spent, there may yet be trouble in the wind.

LEADING ARTICLE.

THE TUBERCULOSIS ROYAL COMMISSION.

THE appendix to the second Interim Report of the Royal Commission appointed to enquire into the relation between human and bovine tuberculosis records the elaborate series of experiments conducted by Dr. Arthur Eastwood, the head of the Commissioners' laboratory at Stansted. Like the postscript of a lady's letter, it contains by no means the least important matter of the communication of which it forms part. The conclusions of the appendix are clear, conclusive, and founded on apparently unassailable observations, although in the light of previous experiences individual experiments must always be received with a certain amount of caution. The two main points emphasised by Dr. Earlwood are: (1) The marked difference in the severity of the morbid processes produced by different viruses; (2) the underlying histological unity which characterises all these processes, from the mildest to the most severe, as typical of tuberculosis. With regard to the first-named condition of activity, it is hardly possible to insist too strongly upon its importance as a pathological factor. The introduction of a virulent virus into the system is followed by tissue reaction which, however vigorous and sustained, is sooner or later overcome by the invading bacilli, and large numbers of bacilli gain access into the general circulation. On the other hand, with a less virulent virus, the invaded tissues are able to offer a resistance that is not only vigorous but effectual. To quote the words of the Report:—"At the site of inoculation (of a mild virus) the tissue reaction is, within a few weeks, completely successful, and a dense, leathery, fibrous zone is formed which completely debars the entrance of the great mass of the inoculated material into the body. The bulk of the inoculated culture, in fact, is as much external to the body as it would be if it were enclosed in a test tube." The second point alluded to, namely, the histological unity of all degrees of tuberculosis, is obviously a matter of vital concern to the ultimate object of the Commission. Dr. Eastwood states with confidence that there is no valid reason for doubting that human and bovine tuberculosis belong to the same family, a fact that was never seriously disputed before the year 1901. The inter-communicability of infection is similarly and consequently accepted. Dr. Eastwood remarks that his work has been especially concerned with the endeavour to ascertain how far it is possible to recognise tubercle bacilli isolated from the human body as being of bovine or other animal origin. The proof that bovine bacilli are a danger to man he regards as established by his researches on evidence that is conclusive and final. As to the identification of human and of bovine bacilli by bacteriological tests and microscopic examination of morbid processes produced experimentally, he points out that the bovine virus when inoculated, produced severe disease with definite histological characters, but it appears that there are many human viruses which are not completely identical with them. The difference, in point of fact, appears to be one of degree. Altogether, Dr. Eastwood's five years of devoted work have resulted in conclusions of incalculable importance to the human race. For obvious reasons it has been out of the question to do more than indicate in the merest outline the scope of his investigations, but all who are interested in the subject will naturally study the original document with minute and careful attention.

Apothecaries' Hall, London.

THE following candidates having passed the necessary examinations, received the L.S.A. Diploma of the Society, during March, entitling them to practise Medicine, Surgery, and Midwifery:—F. A. Bainbridge, A. E. Blythman, A. F. Palmer and W. F. Skinner.

CURRENT TOPICS.

The Development of British Health Resorts.

The neglect of our own spas and seaside places by fashionable folk who are given to visiting foreign resorts, has long formed a subject of regretful comment among medical journalists. Some day the tide of popular favour may happily set in the direction of our own beautiful coast and inland health resorts. If it be patriotic to befriend colonists who fall in under the broad banner of our vast empire, it is surely not a whit less desirable and infinitely more practical to spend our holiday money upon our own spa and seaside countrymen. A first step towards a better understanding is clearly to secure the support of the medical profession, which naturally has a good deal of influence in matters of the kind. From this point of view the work of the Balneological Society deserves the hearty support and co-operation of local seaside and spa authorities. A recent visit of that body to Hastings aptly illustrates the mutual advantages of such an event. A large number of medical men visited that fine old Sussex town and were entertained by the Mayor and by the local medical practitioners. In the course of excursions, receptions, dinners, and other hospitality, a vast amount of the right sort of information was pleasantly conveyed to the visitors. The Balneological Society is full of energy and enterprise, and has already visited many of our most notable spas and seaside towns. Their work is worthy of hearty support by every well-wisher of our national prosperity.

Milkmen and Street Noises.

Of all the curses of modern town life, that of noise is perhaps, from the medical point of view, the most baneful, at any rate so far as the nerves of mankind are concerned. Noise is more than a nightmare to the literary man whose thread of thought is apt to be rudely snapped by every passing jar. Hence the diabolical hotchpotch of discords that makes up the sum-total of street sounds has been again and again delineated in terms both forcible and picturesque. It may be doubted, however, if any single pen has ever done justice to the milkman's contribution to the infernal din. His carts rattle, his cans jangle and crash, and his work goes on from early morn till dewy eve to the accompaniment of a villainous street cry worthy of his flagrant disregard of all the common decencies of life. Why should not the milk-cart have rubber-tyred wheels? Why should not the cans be deposited quietly on the pavement? And why should the milkman have a discordant cry, when the butcher and the baker are silent? Why, in short, should he not conform as far as possible to the rules drawn up by the Society for the Suppression of Street Noises. The indictment against the milkman is already heavy enough without the knowledge recently given to us by science that this noisy tradesman is to a great extent responsible for the tuberculosis in our midst. When we bring the contents of the milk-cans under control it is to be hoped that steps will be taken at the same time to secure distribution of the supply in a reasonably quiet fashion. With some simple but efficient bye-laws in that direction and the general substitution of wood paving for reverberating stone, we may look forward to a quieter and saner future.

The Crime of Abortion.

Last week an ex-medical man was sentenced at the Central Criminal Court to ten years' penal servitude for the crime of procuring abortion. The man in question, Caleb Whitefoord, was an old offender, for some time ago he underwent a sentence of five years' imprisonment for a similar illegal act, and his name was subsequently struck off the *Medical Register*. Happily this particular offence is rare among medical men, although there is no reason to doubt that it is of extremely frequent occurrence in other classes of society. One curious fact is the immunity with which abortion may be practised for many years by persons who are in some instances of notorious reputation in that direction. The police are naturally loth to act unless they are able to secure evidence likely to lead to a conviction, a state of affairs that is often extremely difficult to compass in dealing with this kind of criminal. At the same time it is somewhat of a mystery how certain well-known offenders, sometimes within, but more often without, the pale of the medical profession, are allowed to escape scot free for many years together. There can be little reasonable doubt that the modern revolt against child-bearing expresses itself to no small extent in the prevalence of this medico-legal crime.

"Doctors, Limited."

It is much to be hoped that the two Bills introduced into the House of Lords this session by Lord Hylton will have a good chance of reaching the Statute Book. These Bills are designed to prevent persons in the one case from trading as doctors and in the other as dentists, under cover of the Companies Act. It is a serious scandal that unqualified persons have only to band themselves together, form a bogus company, and register it, for them to be able to carry on business under the title of doctors, dentists, surgeons, or whatever title they wish, without the General Medical Council or any other power being able to touch them. The Board of Trade should have power to refuse to register an obviously fraudulent company, and any company trading under medical titles obviously is fraudulent. Lord Hylton's Bills simply ask Parliament to declare that whatever would be an offence under the Medical Acts when committed by an individual person shall also be an offence when committed by a number of persons formed and incorporated into a company—surely a very modest request. The British law, as a rule, regards an offence to be aggravated when brought about by conspiracy instead of by individual sin, but with that delightful paradoxical way in which the law as regards medicine is laid down, it is not wrong to do by agreement what is wrong if done alone. If Parliament has any sense of humour, to say nothing of that of justice, these two useful little Bills will glide through without opposition. But the quack companies are sure to have secured some Parliamentary sympathisers to oppose them.

Suffragettes and Hysteria.

IT is noticeable how little the word hysteria has been used in connection with the suffragettes. Two reasons might account for this. Either the relationship between screaming and struggling women and hysteria is too obvious to be worth mentioning, or the already terrorised male fears to deflect the current of their wrath from the broad chest of the policeman to his own unlucky head. But where man fears to tread, an angel has slipped in in the person of Miss A. E. Bertram, a lady who has put forward the physiological argument that owing to the hysterical nature of women it is undesirable that they should sway the national destinies. Naturally a flood of hysterical letters have descended upon her, either denying that women are hysterical, or asserting that men are hysterical. Miss Bertram, however, is a philologist as well as a physiologist, and she points out that whereas it is no crime for a woman to be hysterical, man is etymologically absolved from any association with the complaint. The special calls on the nervous system of woman, she says, are such as to excite in a special degree those peculiar functional disorders of the nervous system, characterised by increased irritability to physical and psychical stimuli. There is a remarkable amount of good sense and good physiology in these words, and we think it a healthy sign of the Home Secretary's nervous stability that he has not opposed hysteria by hysteria, but has been content to undo metaphorical stays and pour metaphorical cold water on those hysterical women whose psychical irritability culminates in unseemly gymnastics in the precincts of Westminster.

Coventry Dispute.

WE sincerely trust that the splendid fight being waged at Coventry between the medical staff of the Dispensary and the Committee will end in a complete and signal triumph for the doctors. The point at issue is a vital one, namely, whether the profession is to be the tool of interested laymen or whether it is to determine fair conditions of practice for itself in conjunction with its patients. In no town probably does systematised contract practice prevail to the extent that it does at Coventry, there being no less than 18,000 members of the Provident Dispensary. The medical men are claiming a wage limit, the abolition of a privileged staff, and proper medical representatives on the management. If contract practice is to be carried on under anything like fair conditions these points are of the most urgent and the most necessary, and the medical men are having a long and tough fight for them. They may rely on the hearty approval of their confreres all over the Empire. The latest phase of the struggle is that five members of the staff, Drs. Pickup, Hird, Fenton, Heal and Arch—all honour to them—have resigned their appointments. It is not clear why the two remaining ones, Dr. McVeagh and Dr. London, have not done so too. In this great struggle for justice we hope we can confidently depend on the honour of the profession not to supply any "blacklegs." Any medical man seeking to undermine the work of the local members of his profession by offering his services to the Dispensary under the present conditions would deserve the severest reprobation from all right-thinking people. United we stand; divided we fall. May Coventry herald a new era of fair dealings between the profession and the public!

Ammanford Collieries Fight.

ANOTHER fight is in progress with the Ammanford Anthracite Collieries Branch of the South Wales Miners' Federation. Here the points are much the same, the wage limit being as much to the fore as ever. It is a curious and, we may add, disturbing factor in the industrial situation that the Trade Unions who have fought for justice for their own members, and in the main obtained it, treat with dislike and opposition any similar demands on the part of the medical men. Competition has its good points, but unrestricted competition can only lead to sweating and oppression. Combination or trades unionism in one form or another is the obvious and proper remedy, and we cannot conceive how those who have found out its blessings can wish to deny them to their best friends in times of ill-health and sickness? Their sense of fair play should be sufficient alone to restrain them from withstanding medical unity and reasonable conditions of service. In the district under notice one medical man is reported to have said that he has to attend a farmer, possessed to his knowledge of £12,000, for half-a-crown a year, each visit entailing a journey of over four miles. Can the trades unions produce a fact to compare with that for meanness?

Women and Public Health.

THE movement inaugurated by Her Excellency the Countess of Aberdeen to interest the women of Ireland in matters of public health is one that deserves the best support. In these questions medical men can only direct the way; no advance can be made without the formation of a sound public opinion. In Dublin probably more than anywhere in the Kingdom is there room for the exertions of an association endeavouring to rouse public opinion, for nowhere else would the present scandalous condition of public health be tolerated with equanimity. It is possible, however, that the enthusiasm roused by the starting of Lady Aberdeen's Health Association is a sign of better things, for it is not often that the College of Physicians is able to give hospitality to such a large and interested meeting as the inaugural meeting held last week. His Excellency, the Lord Lieutenant, in the regretted absence of Lady Aberdeen through illness, explained the objects of the association. We are glad to see in the forefront the subjects of consumption and infantile mortality, for it is precisely in reference to such questions that the work of women can be most effective. We are glad to note, too, that the new association wishes to make it clear that it intends to run as a colleague and not as a rival to existing associations whose objects are in any way similar.

Medical Men under the New Compensation Acts.

THERE are many interesting problems under the new Workmen's Compensation Act, and it seems not improbable that some of them at least will have to be settled in the Law Courts. The question of whether a practitioner is to be liable for accidents to his locum tenens arising in the course of the employment of the latter is one of them. If the payment is at the rate of £250 a year, in all probability the question of liability will not arise, as anyone receiving that amount of wages cannot claim. If, say, the rate is at £150, then an assessment of value of board and lodging will probably bring the sum up to the minimum £250. A locum at £100 might reasonably claim under the Act. The majority of qualified assistants, house surgeons, junior medical officers, and so on, would be clearly entitled to compensation provided their total honorarium in money or in kind did not exceed £250 per annum. In some of the leading London hospitals it is the custom to give an honorarium of 50 to 100 guineas to members of the visiting medical and surgical staff. It is interesting to speculate as to the responsibility that would be incurred by the hospital authorities under these circumstances should any of the staff thus receiving money be injured in the performance of duties connected with the work of the institution. Doubtless many shrewd difficulties will arise in the administration of this drastic but evolutionary Act, which, readers may be reminded, comes into force on July 1st next.

The Marriage of Consumptives.

AMID the rush and excitement of modern scientific progress, there is a constant tendency to forget old friends in our worship of new and strange gods. In the case of tuberculosis we find the problem attacked from every possible coign of vantage afforded by the bacteriologist and the sanitarian. Latterly we have been advocating the rigorous control of dairies and of flesh used for human consumption in order to exclude the ubiquitous bacilli of tuberculosis. But, of all obvious predisposing causes of the malady, the marriage of tuberculous persons is perhaps the one most neglected. In the days before bacteriology was born, our less scientific ancestors attached an exaggerated value to the heredity of the disease. Nowadays all that is changed, and medical men readily pass many candidates for life insurance who have a family history of phthisis. Sometimes a man with an early history of undoubted pulmonary tuberculosis is able to secure a life policy. Professor Karl Pearson has recently pointed out that the elder offspring of tuberculous stocks appear subject to tuberculosis at a far higher rate than the younger members. This observation would be of practical use in any attempt to limit the marriage of persons having a marked tuberculous history. Probably in the light of modern knowledge, no serious proposal would ever be made to prohibit marriage to any but those showing evidence of active tubercle. Before the world has educated itself up to so exalted a pitch of philosophy, however, it seems highly probable that tuberculosis will have been stamped out of existence. The broader question of the prevention of marriages among the insane, the syphilitic, and the otherwise unfit, remains to be considered. Some day in a remote future the serious problem of race degeneracy may be partially met by a more scientific control of the processes of generation. So far social reformers have barely touched the fringe of the subject.

PERSONAL.

HER MAJESTY THE QUEEN has kindly intimated that she will attend on June 13th to perform the opening ceremony of the Fete for Crippled Children at the Mansion House to be known as "The Queen's Fete."

H. R. H. THE PRINCE OF WALES will preside at a dinner to be held at the Hotel Cecil on May 14th in aid of the National Sanatorium for Workers suffering from Tuberculosis.

DR. E. B. HURST HUGHES has been appointed Resident Medical Officer of the Swansea Workhouse Infirmary.

SURGEON LIEUT.-COLONEL G. J. COATES, R.A.M.C., has been selected for charge of the Military Hospital, Cork, taking over the duties forthwith.

MR. WILLIAM HENRY POWER, C.B., F.R.S., medical officer of the Local Government Board, has been appointed to be chairman of the Royal Commission on Tuberculosis, in the room of the late Sir Michael Foster.

D. F. M. SANDWITH has been appointed Gresham Professor of Medicine in place of the late Dr. E. Symes-Thompson.

THE news of a fanatical outrage has just come from Morocco, in which a French medical man, M. Mauchamp, was the victim. He erected a pole and hoisted a white flag in front of his house, a large crowd gathered and ultimately stoned the unfortunate. Dr. Manchamp was formerly for five years official French physician at Jerusalem.

THE authorities of St. Mary's Hospital Medical School (University of London) having had under consideration the proposal to concentrate the preliminary and intermediate medical studies at an institute of medical sciences at South Kensington, have decided not to participate in this scheme, but to continue to maintain as hitherto complete courses of instruction in these subjects in the medical school.

A Clinical Lecture
ON
POINTS OF INTEREST CONNECTED WITH TROPICAL SANITATION. (a)

By RONALD ROSS, C.B., D.Sc.Dub., LL.D., F.R.C.S.Eng., F.R.S.,

Professor of Tropical Medicine in the Liverpool University.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

The subject of tropical medicine is a very large one, and it is difficult to select the particular points which will interest you most. Nor do I know what amount of detail I ought to give. It is always difficult to know how deeply one ought to go. And obviously you are not all experts, or you would not be here. I think it will be better to assume that you have a moderate knowledge of the subject, and the best way will be to speak to the lantern slides, a large number of which I shall show you dealing as much with the points of scientific interest as the time will allow. I shall confine my remarks chiefly to three points: First, the disease known as sleeping sickness; secondly, yellow fever, thirdly, malaria in various parts of the world, and its prevention. Of course, I shall devote attention to that aspect which interests you most—prevention.

Sleeping sickness occurs in animals and in man in Africa, and it is due to a parasite called the trypanosome. It lives in the blood, and is carried from one animal to another by the tse-tse fly. Closely allied parasites, though not quite the same, are also found in beasts and in birds. Closely similar ones are also present in fish and in insects. The disease is a very important one, and is becoming more so, not only because of the mischief it does to cattle and domestic animals, but because it is killing large numbers of men in Africa at the present moment. It is very much "in the air," so to speak, like influenza, and therefore you may be interested in hearing one or two points about it. I show you photographs of an animal and of an African native suffering from the disease; the pictures are those of Colonel Bruce, who is now in London. For the purpose of studying the disease, the Royal Society has sent out several Commissions, and the Liverpool School of Tropical Medicine has sent out many. Professor Koch is also studying it now. The parasite causing the disease in man is now generally accepted to be the Trypanosoma gambiense, and was discovered by Ford and Dutton, of the Liverpool School. Dutton, I regret to say, lost his life, a martyr to his researches. A patient with this disease is sleeping constantly, and can hardly be roused. This, however, is the terminal symptom of the disease; at first, the patient hardly feels anything at all. The parasite is found in only small numbers, comparatively, in the human blood; but in animals it is very plentiful. Later on, the parasites cause enlargement of the glands, at the back of the neck especially, so that this presents a ready means of detection in a comparatively early stage, before the sleepiness becomes pronounced. Later on, the parasites find their way into the cerebral fluids, and cause this symptom. The pathology of it, however, is not quite so simple as that. Finally, the patient falls into a condition of almost absolute coma; he becomes more or less emaciated; then suddenly the temperature, which had been above the normal, falls, and the patient sinks and dies. We are studying the tse-tse fly very minutely in Liverpool, where we have a special entomologist, Mr. Newstead. It would occupy several lectures to give you the whole anatomy of the fly; but we know as much about these flies as we know about ourselves, if not more. Still, their bionomics are not known as well as they ought to be. They only produce one young, which is a larva, and shortly becomes a pupa, and takes five weeks to develop into a mature fly. I show you a photograph of trypanosomes, taken by the "thick film" method. What is spoken of as the nucleus is, I think, more than the nucleus. A few weeks ago, Professor Moore, of our University at Liverpool, and myself, published a note in the *British Medical Journal*, in which we drew attention to this point concerning the nucleus. I show you drawings of trypanosomes made by Professor Moore, the cytologist on the Cancer Research Committee in Liverpool. The "wet" method of preparing and staining is probably the best and more correct, and we should use for parasites the same stains, &c., which cytologists find best. An authority on the subject spoke to me of the "dry" method as "barbarous," and I am inclined to agree with him. I show you also a photograph presenting a dividing nucleus, but whether it is by spindle or by amytotic division I cannot say.

With regard to the cure of the disease, it is often remarked that prevention is better than cure; but we are beginning to find out, in several instances, that the only way of preventing a disease is to cure it. One way in which to reduce the prevalence of the disease trypanosomiasis in man is to cure the patient by killing the parasite in him by appropriate drugs. He then ceases to spread the disease, and thus cure becomes a part of prevention. In malaria, the same thing is done. According to Koch, one way to prevent the spread of malaria is to kill the parasites in man by quinine. In trypanosomiasis we cannot get rid of the carrier of the germ; the fly cannot be got rid of so easily as can the mosquito, apparently. The important thing to sanitarians is, How are we to prevent this disease? Remember it is prevalent among the poorest natives, and over large areas of almost wild country. You can hardly get the natives to protect themselves from the bites of the insects, and they cannot spend their lives in mosquito nets, they must frequent the edge of the water to draw water and do their fishing, and go about in canoes. The result of the consideration of how to prevent the disease has been almost to cause despair, and the other day a certain Committee, almost decided to give it up. There was only one way in which to prevent it, and that is to cure it. We are at a loss to know how to kill the parasite in man. If you kill the parasite you may kill the host also. Professor Koch has been using atoxyl, which was first suggested by Drs. Thomas and Breinl. It has a great effect on the parasites in the experiments conducted on animals. Dr. ——, of Liverpool, has been at work on the subject in Liverpool, and I hope he has now got a better drug than atoxyl. It is difficult to tell what is the effect in human beings, because they may live as long as eight, nine, or even ten years with these parasites in their blood—that is, in the peripheral blood and yet such patients may ultimately die of sleeping sickness. But atoxyl should be used because it produces great temporary alleviation. There is a method which has been recommended by Dr. Todd, that is, quarantining the trade routes.

(a) Delivered at the Royal Sanitary Institute, London, on Friday, March 1st, 1907. The Chair was occupied by the President of the Institute, his Grace the Duke of Northumberland.

The disease is now spreading quickly in Africa chiefly owing to our civilization, which enables large areas to be traversed by caravans, where formerly it moved very slowly. It is easy to diagnose the early stage of the disease by the enlarged glands in the neck, which I referred to, and Dr. Todd's scheme is that no caravan shall be allowed to take a native who has these enlarged glands from village to village. In a few months we shall be sending an expedition out to attempt this method, and we hope it will lead to something promising. There is already a frightful loss from the disease, as it kills nearly every patient, and some districts are almost depopulated by it. Nevertheless it does not cause so much sickness as do dysentery and malaria throughout the world.

Now as to yellow fever. This disease is known to be carried by the tiger mosquito, so called because its legs are banded like a tiger, and because it bites like a tiger. Though this is found nearly everywhere in the tropics it is curious that yellow fever is carried by it only in certain parts of America (Central), the West Coast of Africa, and Spain. The history of the discovery of this mosquito as the carrier of yellow fever is a startling and dramatic one. The disease exists chiefly on the Island of Cuba and in the district of Panama, whence it spreads to other parts, and the mortality from it is, roughly, one in four. Naturally the prosperity of the Island has been much impaired by the disease, and up till 1883 nobody could conceive how the disease was carried. In that year a British subject, Dr. Finlay, of Havana, suggested that the disease was carried by the mosquito, and he also carried out a number of experiments directly on human beings. Spaniards coming to Havana went to a medical man to be inoculated against the disease; as if they were going to be sick they would prefer to be so in Havana where they could be properly treated and looked after. And Dr. Finlay availed himself of that fact to indicate that the mosquito carried it. The discovery is of the utmost importance to the New World, and I hope that some day the British people will do something to thank or reward Dr. Finlay, who has not had a "Thank you" for his work up to the present. In the year following the conquest of Havana by America, the Americans set to work to study the disease, and sent out a Commission. One of the members of it—Dr. Lazear—watched a mosquito biting his hand, and said: "I wonder if this mosquito is infected. If so, I shall have the disease." Sure enough, he acquired the disease in a few days, and died. They made some admirable experiments on human beings, and Spaniards volunteered for the purpose. They built a house, and brought Spaniards in and tried to infect them with the clothes worn by yellow fever patients, but not one of them caught the disease. Another seven they caused to be bitten by this mosquito, and six of them were attacked. Twelve days is the extrinsic incubation period. A repetition of the experiments produced the same results. At New Orleans one and a half years ago, there was an outbreak of yellow fever, and the Americans set to work at it with great energy and broke the back of the epidemic. The Americans are very active in an emergency and when danger threatens. Surgeon-General Wyman sent a whole army of naval and army officers and men to cope with the disease, and with admirable results. I wish the Americans were as good sanitarians always, but those who have visited such cities as Baltimore, or even Chicago, will know that they are not nearly equal to ourselves in these matters. The Municipality must keep an efficient army of workers, and pay enough for the work; and they must attack the evil from every point of view. The mosquito which carries the disease lives largely in the roof, and I show you a photograph of men spraying a house which is infected. It is necessary to destroy every mosquito possible. This may be done by fumigating the whole house, first filling up with paper all cracks and crevices. A very good mixture for this purpose is equal parts of carbolic acid and camphor put on a heater, from which the fumes rise. A doctor in the district visited by the epidemic did not believe in the mosquito theory, and refused to obey the instructions, so he was promptly carried off to jail. Wire gauze is very largely used in Central America; it, of course, also protects the inmates from ordinary mosquitoes, as well as from flies and wasps. I only wish wire gauze was more used in British dominions. However, it is being used more now than formerly. I always recommend that wire gauze should be used in the tropics. It is costly in Panama; what costs us 2d. here costs there about 1s. The mortality from the disease at Panama while the French were working there was frightful; I was told by the British Consul that 50,000 persons died of it there while the French were working at Panama. When the Americans took up the work, they saw that the first thing to do was to get rid of the disease. They appointed Colonel Gorgas to tackle it, he having already done such good work in Havana, though he has had very little reward for it. There has been a gradually diminishing mortality since the Americans conquered the country in 1898. The disease was first attacked by ordinary methods of sanitation—isolating contacts, &c.—and they thought they had produced an appreciable result. But after that the yellow fever came back the same as ever. So General Wood, who had command of that Colony, gave the order that the mosquito must be attacked. General Wood was originally a medical man, and he knew the value of scientific methods. He said that no expense was to be spared. The table I show you presents the results. The period is not carried further because there were no cases. But last year, I am sorry to say, fifty or sixty cases occurred, probably because, having conquered the disease, they got a little sleepy over their work. The same methods are being adopted in Panama against malaria and against yellow fever, and the returns for November and December show that the numbers of cases have been greatly reduced. Americans feel confident that they can keep down the disease, and it is well under control, in spite of newspaper scares. One of our principal allies is a little fish not quite threequarters of an inch long, which, when put into puddles eats up the larva. They actually have a "mosquito engineer" there—Mr. le Prince.

Dr. Laveran discovered the parasite of malaria; he is working at the Pasteur Institute, and he has also done much work in connection with trypanosomiasis. Probably the mortality from malaria in India approaches five millions, but you must remember that the population of the country is 300 millions. There must be a very large death-rate from malaria seeing the large number of children who are infected. It is not a disease which kills directly; it does so by enfeebling the patients. One can get a good idea by studying the admissions to hospital of soldiers and convicts. Many people who fall sick with malaria do not come to hospitals. On the whole I estimate that the number of attacks of malaria during a year equal about half the population. Cholera attacks a smaller number of people, but the death-rate is much higher. Probably the death-rate from malaria is higher than it seems because many of the deaths really due to it are returned under intercurrent affections. Amongst the European troops in India 710 men on the average are constantly in hospital for the disease—or equal to a whole regiment. Besides that hundreds of troops are taken ill when going on active service, largely through relapses. This is a large item of expense in connection with military expeditions. Sometimes cases of ankylostomiasis and kala azar are included under malaria. If a patient has chronic malaria through not having been properly treated and is then dosed with quinine, an attack of black-water fever is precipitated, as was shown by Koch and others. I show you a number of slides illustrating the subject. The anophales mosquito sucks up the parasite, which passes through the stomach wall into the body cavity, and then the spores find their way into the salivary glands. They get into the lumen of the salivary duct, and are projected into the skin of the patient when he is bitten. They live in the mosquito nine days, whereas in the case of yellow fever the period is twelve days. We have not discovered the yellow fever parasite. The ancient Romans understood the value of drainage in reducing malaria, for we find Mark Antony, when a candidate at an election, promised to drain the Pontine marshes if he got into power. When he got into office, he forgot all about it, and the marshes remained undrained. The anopheles breed principally in stagnant water, natural collections. The great outstanding principle in tropical sanitation is, have no puddles or stagnant water in your town area. Sierra Leone is known as the "White Man's Grave," and I show you a series of photographs by which you will see the enormous number of puddles in the streets; the rainfall there is very heavy. There are several ways of dealing with the disease — draining away or filling in the puddles, killing the parasite in the patient, having proper gauze mosquito nets. The advantage about draining the puddles is that it does not involve taking a nauseous drug, nor covering one's house so that it looks like a meat safe. A gentleman gave £2,000 towards this work in Sierra Leone, and we sent an expedition out there. I went with Dr. Logan Taylor. I do not think the authorities backed us up enough. A good deal of work has been done at the mathematics of the mosquito, and Professor Karl Pearson has been dealing with the subject. People have asked whether the insects will not come in from the outside and spoil the effect of the drainage, and perhaps be blown in by the wind? It is a statement which is made by those who have not carefully considered the matter. Every mosquito which may come into a given area is lost from the outside. Moreover, a wind which will blow mosquitoes into a particular area will also blow them out again. Professor Karl Pearson has shown, in what he calls the problem of the "random walk," that, except for some special attraction, the chances of a mosquito continuing always in one direction is almost infinitely small; the chances are that a mosquito starting from a particular spot will end up not far from where it started. A great effort is being made to lessen the amount of malaria in Greece. Greece is the birthplace of civilization, and the carrying out of this great work will constitute a fitting climax to the antimalaria campaign. We sent them £200 towards their work. There is a great deal of drainage being done, and a determined band of men are at work in the country. Although malaria is rife in Italy, there is said to be half as much again in Greece. The question of disease and history is a very important one, and I do not doubt that malaria has sapped the national life in Greece; which has waned since the time of Pericles.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by F. J. Poynton, M.D., F.R.C.P., Lond., Physician to University College Hospital, London, Assistant Physician to the Hospital for Sick Children, Great Ormond Street, on "Observations on Arthritis." The lecture was delivered at University College Hospital, and will be illustrated.*

A petition has been forwarded to the Home Secretary and to the President of the Local Government Board by the Women Sanitary Inspectors' Association opposing Mr. Ramsay Macdonald's Home Work Regulation Bill, on the grounds that the sanitary regulations are unnecessary, being already provided for in the Public Health and Factory Acts; that the proposed licences would prove a hindrance to the sanitary authorities in carrying out their duties with regard to infectious disease; that the placing of autocratic power in the hands of one individual, whether an officer of the State or of a municipality, is strongly to be deprecated; and that the intervention of the magistrate is necessary in revoking licences as a protection both to the licence and to the inspector.

ORIGINAL PAPERS.

A CASE OF
CANCER OF THE OVARY,

INVOLVING THE SIGMOID FLEXURE. REMOVAL OF BOTH OVARIES AND EXCISION OF PART OF THE SIGMOID, WHICH WAS UNITED BY END-TO-END ANASTOMOSIS.

By FRED. BOWREMAN JESSETT, F.R.C.S.,
Senior Surgeon, Cancer Hospital, Fulham.

Mrs. W., widow, æt. 48, was sent to me by Dr. Wickham on August 3rd, 1905, suffering from vaginal discharge.

She had had four children. Menopause occurred about six months previously. Since April she had been suffering from an irregular vaginal discharge, sometimes sanguineous and at other times watery.

She was a healthy looking woman, well nourished and very active. No tenderness or fulness on abdominal examination was found.

Per vaginam, the os is seen to be eroded and thickened; bimanually a small tumour can be felt, apparently connected with the posterior surface of the uterus. The uterus is somewhat enlarged, but quite mobile. There was no discharge coming from the uterine canal. I considered the discharge came from the eroded os uteri and advised some local treatment with douches, at the same time impressing upon her to let her medical man see her from time to time. The small tumour which I took to be a fibroid caused her no inconvenience, so I recommended her to leave it alone, but if it increased in size it would have to be dealt with

She improved rapidly under treatment, and I saw no more of her until the first week of November of 1906, or about fifteen months after she first consulted me. She had then seen Dr. Wickham again, who found a good-sized tumour in her abdomen, and sent her on to see me at once. I found her with a tumour extending nearly to the umbilicus and somewhat fixed. *Per vaginam.* The os was found to be quite healthy, but a tumour was felt connected apparently with the posterior wall of the uterus in the pouch of Douglas. Bimanually this tumour was evidently one with that felt by the abdomen. The whole tumour was somewhat fixed, but seemed to be connected with the uterus. I advised early operation, looking upon the case as a rapidly growing myoma of the uterus.

On November 3rd, with the assistance of Dr. Wickham, I operated through an incision in the middle line below the umbilicus; on the abdomen being opened a large tumour presented itself, to which the omentum and intestines were adherent. These were separated fairly easily, but on passing my hand down behind the tumour to lift it out of the pelvis I found it was firmly connected with the sigmoid flexure, which it had pushed across from the left side. There was no ascites. The adhesions were so strong and the intestines so intimately connected with the tumour that I found it impossible to separate it without tearing its covering. As the tumour had all the appearance of being malignant I was loathe to cut any of it away and so release the bowel, and so I excised a portion of the intestine. Having

---

(a) Read before the British Gynæcological Society, March 14, 1907.

done this I was then enabled to lift the tumour out of the pelvis. This proved to be the left ovary. I ligatured the pedicle and removed it. I then examined the other ovary, and, as that was unhealthy, I removed it as well. Subsequently Dr. Paine, whose report I append, pronounced both ovaries to be malignant, *vide infra.*

I then proceeded to unite the sigmoid flexure by end-to end anastomosis, which was a very difficult matter, as I had neither bobbin or intestinal clamps, and the portion removed was very low down, almost at the junction of the rectum.

I however succeeded in uniting the two ends. For safety sake I anchored the part to the abdominal wound, so that in case of accidents it could be found readily. The abdominal wound was then closed in layers, and the patient returned to bed. She bore the operation very well, and all went well for the first forty-eight hours. But we could not get any action of the bowels and the abdomen was becoming very distended. On the third day, as the patient was becoming more and more distended and no action of the bowels had taken place I thought it wise to open the abdominal wound and see if there was any knot or other reason for the bowels not acting. I found the anastomosis quite intact, and so far as I could see there was no other reason than paresis of the bowel to account for the non-action. I took the precaution, however, of fixing a portion of the sigmoid in the proximal side of the anastomosis to the abdominal wound so that in case the bowels did not act an opening might be made for their evacuation. Happily, however, this did not become necessary and first flatus and then liquid fæces passed *per viam naturalem.* All went well for a fortnight, when the temperature commenced to rise and the patient complained of pain in the abdomen. In the course of a few days pus escaped at the lower angle of the wound, followed by fæces. This continued open for some weeks, but gradually became smaller and smaller. In the meantime some of the sutures which connected the ends of the intestines came away, though the wound and the sinus rapidly closed. Bowels acting regularly. This is an interesting case in many points of view. In respect to diagnosis, the small tumour when first seen appeared to be intimately connected with the uterus,. There was no pain or discomfort caused by it, neither did digital examination nor pressure cause pain, which one would have expected from an enlarged and diseased ovary. Yet I cannot but regret I did not advise operation at that time. The case emphasises the necessity of early operation in small tumours connected with the uterus. It also is interesting as showing how frequently if one ovary is the seat of malignant disease the other will also be found to be similarly affected. According to Olshausen the disease is bilateral in 50 per cent. of cases.

The greater number of recorded cases are usually secondary, but there is no doubt that cancer may arise primarily in the ovary.

Steffeck was able in one instance to trace to his satisfaction the origin of the cancer to the epithelial lining of the Graffian follicles, thus proving conclusively the possibility of a primary origin of the disease of the ovary. Doran has also recorded cases.

Pathologist Report by Dr. Paine.

DOUBLE OVARIAN TUMOURS.

Both ovaries were found microscopically to present the characteristics of an alveolar carcinoma of the ovary, but in different stages.

The larger of the two which was solid and rather soft was seen to be cellular and growing actively. The growth had become atypical, the aggregated masses of epithelieum showing in parts tendency to degeneration (mucoid in character). The fibrous stroma which was ill-developed being infiltrated with a large number of inflammatory cells.

The smaller growth was less advanced and more typical; in it the arrangement of the ovarian tissue could be more readily traced; and there was less tendency to degeneration.

PRIMARY CARCINOMA OF THE VAGINA. (a)

By H. MACNAUGHTON-JONES, M.D., M.A.O.

The patient from whom the growth shown was removed was a woman, æt. 65, a widow, who had been thirty-eight years married. There had been four pregnancies. She had a vaginal discharge for two years. The growth had not, however, been discovered until one week before I saw her, when she had come a long distance by train, and was carried into my study. I found a fœtid mass inside the vulva; the bladder was distended, and I drew off some four pints of water. The patient was too exhausted to make a complete examination, as she had been suffering from sciatica, and the pain she felt on movement of the limbs made it most difficult.

On the fourth day, I removed the growth under the scopolamin, morphia and chloroform method of anæsthesia. Part came away as a slough. I found it grew from the lower border of the lateral wall of the vagina, and that it descended deeply into the connective tissue and encroached on the bladder. It was botryoidal in character, and the deeper part was pedunculated—so that I thought it was of sarcomatous type, being similar to a case of sarcoma of the vagina which I brought before the society on a former occasion.

Neither the uterus nor any other part of the vagina was involved, nor were the inguinal glands affected. Severe neuritis in the left thigh was the only other trouble. I ablated the growth, going as deeply as I could into the cellular bed, and then used the cautery freely. She left the home shortly afterwards, as there was no use in detaining her further. (*b*)

"Dr. Cuthbert Lockyer's report was as follows: Malignant growth, made up of branching columns and masses of squamous epithelial cells. The latter are burrowing cell nests, and lie in alveolar spaces, the stroma around consisting of coarse fibrous tissue. There are also present blind tubules lined with columnar epithelium, actively proliferating in a malignant manner. The presence of two types of epithelioma in genital carcinomata is common in elderly females."

Roger Williams, in his paper on vaginal cancer in the *New York Medical Record* (November 30th, 1901) says, that of 9,226 tumours tabulated,

---

(*a*) Read before the British Gynæcological Society, March 14th, 1907.

(*b*) I have now learned that the patient died ten weeks after operation from implication of the bladder.

there were 40 of cancer of the vagina, and 2 of sarcoma. He considers that "notwithstanding its rarity, cancer of the vagina is by far the most common form of vaginal neoplasm. According to Friedl, the medical journals up to 1896 contain records of 130 cases. Roger Williams himself has met with five examples. He places the proportion at 4.3 per cent. of all cases of cancer in women, taking his statistics from the chief London hospitals. Gurlt, from the Vienna hospitals, gives it at 1.6 per cent. In Hamburg, of 7,498 cancer deaths tabulated by Reiche, only 29 were from the vagina —that is, 0.38 per cent., and of Reiche's 4,507 cancer cases, 1.1 per cent. were vaginal. Williams, averaging these latter results, comes to the conclusion that some one per cent. of all cancer in women is of vaginal origin. Williams notes some interesting clinical and histological facts in connection with vaginal cancer. Briefly stated these are :—

(*a*) Vaginal irritation does not appear to play a part in its production. Pessaries exert no influence.

(*b*) Nearly all primary vaginal cancers appear to partake of the squamous epithelial or epidermoidal type.

(*c*) Having discussed the histological features of the vaginal membrane, in the comparative absence of pigment and glandular structure, as also its embryological development, he divides the forms of vaginal cancer into two—tubular and lobular.

The tubular begins "in proliferating cells of the inter-papillary region of the rete mucosum, or its aberrant extensions growing into the adjacent stroma." Multiplication and development proceeding, knobby projections and ingrowing columns result ; these may grow slowly, and there may be no dissemination. This gives the chronic type of the disease.

The lobular, and much more usual form, is on the other hand, marked by the formation of nests ; rapidity of growth is common by branchings and anastamoses, and this causes dissemination.

(*d*) Regarding its clinical characters, the posterior wall and upper part of the vagina is the most usual seat ; it may commence either as a papillary excresence, an elastic nodule, or an infiltration, and then follow the usual characteristics of the disease, with all the consequences of dissemination and pelvic involvment of organs.

The initial symptoms vary; pain, discharge and menorrhagia may be present, though before the existence of the disease is discovered it may have made considerable progress. The dissemination may be associated with and followed by metastases in different organs, and suppuration may occur in the inguinal glands (as in Herman's case), which are frequently involved. Death usually occurs from asthenia.

(*e*) The most common period of occurrence is after the menopause. Nulliparæ are as prone as multiparæ.

I have written to a few colleagues on the Continent asking them to give me the results of their experience in regard to primary carcinoma of the vagina. I have had the following replies :—

Professor Fritsch.—During the thirteen years in the Bonn Frauenklinik has not seen one single case of primary carcinoma. In Breslau he had seen four cases.

Professor V. Kronig.—During the two and a half years he has been at Freiburg has not seen a single case of primary carcinoma. Speaking from memory (as the results of his work at Jena and Leipzig were not available) he could only remember having operated on four cases in all, and with the exception of one case the disease quickly recurred.

Professor Jacobs (Brussels) says that in his experience primary carcinoma of the vagina is very rare. He has only met with four cases.

Professor Bumm (Berlin) says that he has only seen carcinoma of the vagina twelve times amongst 433 cases of carcinoma of the female genitalia. In these cases there was only one in which the carcinoma was primary. Cancroid of the portio, and cancroid of the vulva encroaching on the vagina, were not included in this number.

Professor Schottlander (Heidelberg) says that of 150 cases of carcinoma of the uterus he found 44 primary of carcinoma of the vagina. This is above the usual average—2 per cent. is probably excessive.

Professor Franz (Jena) says that of 125 cases of carcinoma of the portio, which he has had in the klinik since October, 1904, there have been two of primary carcinoma of the vagina.

Professor Zweifel (Leipsic, says that in 1906, out of 1,400 cases of carcinoma, there were four of primary carcinoma of the vagina.

Professor A. Martin (Griefswald) regards carcinoma of the vagina as a disease of great rariety. Some of the cases are undoubtedly metastatic and occur after operations for cancer of the portio or for chorio epitheliomea. Operative results are unsatisfactory.

ON THE TREATMENT OF
INVETERATE CASES OF MÉNIERÈ'S COMPLEX OF SYMPTOMS BY HYPNOTIC SUGGESTION,

WITH REMARKS ON THE NECESSITY OF INCLUDING HYPNOTISM AMONG OUR SCIENTIFIC REMEDIAL AGENTS.

By T. WILSON PARRY, M.A., M.D.CANTAB.

ABOUT two years ago I published in THE MEDICAL PRESS AND CIRCULAR (*a*) the case of a man, æt. 44, who had suffered from distressing attacks of Ménierè's Symptoms for eight years, and who had been most successfully alleviated by hypnotic suggestion. The case was the first of its kind that had ever been recorded, and I feel sure it will be of no little interest to such of our profession who may have similar chronic cases coming under their care to hear how this patient has fared during the now nearly two years that have elapsed since it first was published.

The attacks had become so frequent and formidable that the patient had been rendered quite unable to follow his employment. When he presented himself for examination on September 8th, 1904, he was noticeably bald, and he volunteered to me that he attributed this period of ill-health, due to these frequent attacks of Ménierè's Symptoms, to be the cause of his profuse loss of hair, and that it had also aged him much in other ways.

(*a*) THE MEDICAL PRESS AND CIRCULAR, May 3rd, 1905, pp. 445-448; May 10th, 1905, pp. 476-478.

He had also lost over a stone in weight during the previous three months. To use his own words: "The constant attacks I have had during the past eight years have much depressed me, and I am willing to undergo any treatment that may give me even partial relief."

On September 29th, October 7th, and December 1st, 1904, the patient was hypnotised by Dr. A. E. Jones, and the suggestion that there should be no more attacks of vertigo was impressed upon him. He was only hypnotised these three times, and each of these three ocasions only occupied a few minutes. From the dates abovementioned it will be observed that the treatment only covered a period of two months. The results were amazing. From September 29th, 1904 (the date of his first being hypnotised), to April 25th, 1905 (when I went to press), there had been no attack of giddiness, the vomiting had entirely vanished, and even the tinnitus, that had been an exceedingly trying accompaniment of the other more formidable symptoms, had ceased to trouble him as formerly and had become at length quite bearable.

Being anxious to learn whether this favourable condition of things had been maintained, I recently wrote to him, and received the following reply, dated February 6th, 1907:—

"I am in receipt of your letter and very pleased to say that I have been fairly well in health. I have only had slight attacks of giddiness and vomiting at long intervals since I last saw you (if I had done so I should have let you know). I am, however, still suffering from the hissing in the left ear, but that does not affect my health, and so long as the giddiness, &c., keep off, I must not complain, as you and Dr. Jones did me so much good (before seeing yourself and him I was in a very bad state). I may add that the attacks I have had have only lasted on and off for a few hours. I have not had occasion to see any other doctor since I last saw you and Dr. Jones. I suffer a little from nervousness, and after I have done my outdoor work in the morning I have to rest in the afternoon before resuming work; but considering I was under several doctors before seeing you and Dr. Jones, and they did me no good, I have much to be thankful for."

(I must here repeat that the whole honour of this case belongs to Dr. Jones and none to myself. I am merely the scribe.)

Remarks.—I am quite convinced that the value of this method of treatment cannot be overestimated. The general practitioner looks for results. In this case the results were all that could be desired. This case stands out not only on its own merits but as a type of that class of kindred nervous affections of obscure origin which often defies treatment by drugs or such other recognised rational system of treatment that may have done good in similar cases. It is this kind of case that often brings so much discredit upon the medical profession. It is well-known that patients suffering from complaints of this nature often spend their whole lives going from hospital to hospital, practitioner to practitioner, specialist to specialist, as their means will allow, always seeking rest but finding none. Can one wonder that if some practical cure be not effected the patient may often ultimately find himself, though perhaps most unwillingly, in the hands of the quack or Christian scientist? Is it not for us, as a strong, fearless, honourable profession, to lift hypnotism out of the hands of the charlatan and employ it, as a method of treatment, in such cases as are likely to be benefited by it, and have already refused to be ameliorated by all the ordinary recognised methods employed? To this the medical profession should give answer. To my mind, it is as important that there should be classes for practical psychology, where students can learn the art of hypnotism, as there are schools for teaching the essential elements of massage and electricity.

CLINICAL RECORDS.

CASE OF SARCOMA OF THE PAROVARIUM.

By W. D. Spanton, F.R.C.S.Eng. and Edin.,

President of the British Gynæcological Society; Consulting Surgeon North Staffordshire Infirmary, &c.

The patient was a woman, æt. 42, who had been married sixteen years, had two children born alive and one miscarriage twelve years ago. General health very good, never had any illness until five years since, when neuritis of the limbs and head appeared. Catamenia regular about every three weeks up to two years ago, since then had only four or five periods. She was seen by Dr. Dawes on December 15, 1906, thinking herself pregnant, and having noticed enlargement of the abdomen for twelve months. He examined her, and thought she had an ovarian or some other form of cystic growth, which had much the sensation of hydatids from its mobile flaccidity.

I saw the patient with Dr. Dawes on December 15, 1906, and found her looking ill with an enlarged abdomen, containing a fluctuating and apparently cystic tumour. To the right side of the uterus a hard mass could be felt, movable like the base of a multilocular ovarian cyst. The uterus was normal.

On December 20, I opened the abdomen and found a very thin parovarian cyst, which contained about two gallons of clear, straw-coloured fluid, and at its base a solid growth springing from the outer extremity of the left Fallopian tube The growth was removed, the base ligatured, and the ovary left behind. She made an uninterrupted recovery.

The pathological report states the tumour is extensively infiltrated with a spindle-celled sarcomatous growth, which is probably of endothelial origin. It has a capsule of fasciculated fibrous tissue, and the periphery is more or less alveolated by strands of unabsorbed stroma. Towards the centre there are more alveoli and less stroma. No ovarian tissue can be detected.

The interest of the case lies in the sarcomatous tumour forming the base of a simple cystic one, having all the characters of a rapidly growing parovarian cyst. The extreme thinness of the cyst wall is unusual for one of such size. It appears to be quite independent of the ovary.

CASE OF LARGE MYOMA, WITH SARCOMATOUS OUTGROWTH, ABDOMINAL: HYSTERECTOMY.

By W. D. Spanton, F.R.C.S.,

President of the British Gynæcological Society, &c.

A widow, æt. 49, who had one child twenty years before, saw me on January 24, 1907, on account of almost constant metrorrhagia, with a good deal of general abdominal pain and frequent sickness. I found a large, solid tumour, which had been growing for several years, now reaching half way between the umbilicus and ensiform cartilage, and was freely movable. The cervix was small and apparently normal. She was very thin and feeble, but anxious for an operation.

I performed abdominal hysterectomy, leaving the cervix on February 5, without any complications. The interest of the case lies in the fact of the different nature of the uterine tumour and that of the outgrowth, to which the omentum was attached. The report by Mr. J. H. Targett of the uterine tumour was as follows :—"It has the naked eye and microscopical structure of a uterine fibroid, undergoing hyaline and mucoid degeneration. There is nothing suggestive of sarcoma. Here the two conditions are combined, but whether they are related is a very difficult question to decide." That of the outgrowth is "this tumour is a spindle-celled sarcoma. The tissue is dense, with areas of hyaline degeneration in places, and one or two foci of mucoid softening."

We have here an excellent illustration of the association between a simple and sarcomatous growth, and it is a question whether the latter is not simply "matter in the wrong place" and too much of it?

OPERATING THEATRES.

NORTH-WEST LONDON HOSPITAL.

EPITHELIOMA OF THE FLOOR OF THE MOUTH WITH EXTENSIVE SECONDARY DEPOSITS IN BOTH SUB-MAXILLARY TRIANGLES.—MR. MAYO COLLIER operated on a man, æt. 42, who was the subject of a large epitheliomatous growth in the floor of the mouth on the right side with excessive deposit in the neck on both sides. Mr. Collier said that the case came under his care at an extremely late stage, the affection having lasted already some five months, and it had proceeded to a condition which several surgeons had considered hopeless on being consulted. The case had come under Mr. Collier's care four days previously, having been sent to the hospital for an opinion as to the possibility of removing the secondary deposits in the neck. Mr. Collier said that having regard to the otherwise healthy condition of the patient and the mobility of the large masses under the right sternomastoid and at the angle of the left jaw he thought it was justifiable to attempt removal, as the alternative would be a painful and horrible death within at most a few months. The gravity of the procedure about to be adopted was fully explained to the patient, as well as the alternative of a painful and miserable ending if the disease were left alone. The patient being only 42, it seemed a pity to let him drift to destruction without affording him a helping hand. Mr. Collier said that in very few cases were these secondary deposits irremovable; a man who knew his anatomy thoroughly and had trusty assistants could certainly undertake the removal of a large percentage of these growths with a fair prospect of the patient recovering from the immediate effects. With these few explanatory remarks he proceeded to ligature the lingual and to clear out the left submaxillary triangle by the usual curved incision. The patient, who was of very short stature, and who had a thick bull neck, was not a very promising subject for a speedy ligation of the linguals; however, in the course of some thirty minutes the clearance of the whole of the glands and the ligation of the lingual were effected. During the whole of this time extreme difficulty was experienced by the anæsthetist; the patient's breathing had become very difficult and his colour was ominous. At this point of the operation things came to a climax; the patient ceased entirely to breathe and was almost of coal black colour. All attempts on the part of the anæsthetist to draw out the tongue and bring forward the epiglottis, which had apparently collapsed over after opening of the larnyx, were unavailing. Mr. Templeton, who was present and very kindly assisting, most promptly and skilfully opened the trachea and inserted a large tracheotomy tube through which artificial respiration was maintained for a few minutes. The natural breathing and pulse action promptly returned and the operation was proceeded with. Mr. Collier next attacked the right side, and the enormous mass which extended from the side of the larynx almost to the cervical vertebræ was removed. The details of this procedure were carefully and skilfully carried out and in the course of an hour and twenty minutes the whole mass was removed and the lingual safely tied. The patient having now been two hours and a half on the table, the later step of removing the tongue and the floor of the mouth was postponed to a future date, when the man would be in a condition to stand the procedure. Mr. Collier remarked that it would be quite impossible to complete the whole operation in one stage; in these cases, experience has taught that the removal of the tongue and the floors of the mouth may be safely undertaken some fortnight or three weeks later. It was the practice of some surgeons, he said, to remove the tongue and floor of the mouth first and the glands at a later stage, but he pointed out that the patient was much more likely to stand the extensive dissections which are requisite to remove the secondary deposits if he is able to feed and sleep comfortably with an intact tongue and floor of the mouth.

TRANSACTIONS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

MEETING HELD MARCH 22ND, 1907.

The President, Mr. CLUTTON, in the Chair.

Mr. H. H. CLUTTON showed a case of

CONGENITAL HYPERTROPHY OR GIANT GROWTH OF FEET.

The patient was a girl, æt. 17. The deformity, which was noticed by the mother at birth, slowly increased up to the age of fourteen. During the last three years the growth had been much more rapid, producing particularly a greater inequality in the length of the two lower extremities. The feet were enormous, but fairly equal in size, the distal parts being rather larger than the proximal.

Mr. F. W. FORBES ROSS showed a case of

PANCREATIC CYST, OPERATION AFTER RUPTURE OF.

Rupture of the cyst had occurred a fortnight after an operation for rectal prolapse. The contents were purulent.

Administration of hydrochloric acid produced a ready flow of pancreatic juice from the sinus.

Dr. H. BATTY SHAW, and Mr. R. HIGHAM COOPER showed a case of

HYPERTROPHIC PULMONARY OSTEO-ARTHROPATHY OCCURRING IN THE LOWER EXTREMITIES ONLY, IN ASSOCIATION WITH CONGENITAL CARDIAC DISEASE.

The patient was a woman, æt. 21, The patient was cyanosed, and there was well-marked clubbing of the fingers, toes and nose. A systolic murmur was heard over the precordium. The lungs were free from signs.

There was obvious swelling of both legs, largely due to thickening of the bones.

Radioscopic examination.—There was considerable enlargement of the tibiæ and fibulæ of both legs, more especially the right, when compared with the corresponding bones of the patient's sister, who was quite healthy and of similar height. There was uniform thickening of the lower two thirds of the tibiæ and fibulæ, and irregular bony deposits were present at the attachment of the periosteum to the interosseous membranes. The upper halves of the shafts of the femora appeared to show the same changes, but in a more marked degree, especially in the right leg; the head, neck, and lower halves of the femora appeared to be normal.

Dr. G. A. **Sutherland** showed a

CASE OF OSTEOGENESIS IMPERFECTA (? SYPHILITIC).

A male infant, æt. 8 weeks, a first child. He was born after an easy labour, and "the left wrist was seen to be broken and the arm to hang as if dislocated The thigh and leg bones on the left side were broken." Multiple fractures in the long bones were shown in a skiagram taken seven days later. No fresh fractures had occurred.

On admission, four weeks ago, great pain and tenderness were present in the extremities, which were the seat of periosteal swelling, especially around the epiphyses. A condition of pseudo-paralysis existed, movement being limited to the fingers and toes. Signs of fracture were manifest in all the long bones of the extremities and in many of the ribs. A swelling was present over the right parietal bone with a large irregular gap in the osseous tissue. There was general peeling of the skin over the trunk and extremities. Under observation improvement had occurred. Mercurial treatment has been carried out.

Dr. **Leonard Guthrie** thought that some, but not all of such cases were due to syphilis. The cases might be divided into two groups according to whether the fractures were found only at birth, or occurred at a later period. He read the notes to a case similar to the present one, including an account of a careful *post-mortem* examination. He also mentioned two cases that had first shown signs about the age of two years.

Mr. W. G. **Spencer** suggested that the condition might be due not to disease, but to an arrest of development. If this were so, later improvement might be wrongly attributed to mercurial treatment.

Dr. **Sutherland**, in reply, said that in his opinion the present case was probably syphilitic; the spleen was large, there was ulceration about the arms, and the case had responded to mercury. If so it should not be placed in the idiopathic osteogenesis imperfecta group.

Mr. A. H. **Tubby** showed

A CASE OF FACIO-HYPOGLOSSAL ANASTOMOSIS FOR POST-OPERATIVE PARALYSIS.

Patient was a male, æt. 19. An abscess was opened on April 27th, 1905, and when he recovered from the operation he found the left side of the face paralysed. On admission to Westminster Hospital there was facial palsy, and the patient had lost all taste on the anterior part of the left side of the tongue. On October 16th an anastomosis was carried out. An incision was made with a tenotomy knife deeply into the hypoglossal nerve, and the distal ends of the facial were implanted into it laterally. On October 23rd it was noted that the palebral fissure was lessened in size, and the eye could be temporarily closed. On October 28th the patient began to move the left angle of the mouth. At present movement was almost perfect; there was slight atrophy of the left side of the tongue.

Mr. A. H. **Tubby** showed

TWO CASES ILLUSTRATING THE TREATMENT OF COMPLETE PARALYSIS OF THE GASTROCNEMIUS AND SOLEUS WITH TALIPES CALCANEUS, BY NERVE-GRAFTING.

The patients were both æt. 9, and had old standing poliomyelitis. The nerve branches to the muscles had been isolated and implanted into the external popliteal nerve. The results were excellent.

Mr. W. G. **Spencer** thought that physicians should decide on a limit beyond which spontaneous recovery was impossible in these cases, and then call in a surgeon.

Mr. **Tubby** said that the distinction was not always clearly made between the direct effect of muscular paralysis and the secondary effects of contractures. If this were done surgical measures would often be resorted to earlier.

Dr. F. **Parkes Weber** showed a case of

ACUTE THYROID SWELLING, WITH ACUTE HÆMORRHAGIC ŒDEMA OF THE RIGHT SIDE OF THE PHARYNX AND LARYNX.

The patient was a man, æt. 54. He was under treatment for interstitial nephritis, and had a blood pressure of 230 mm. On the afternoon of March 4th his neck suddenly began to swell. On admission to the German Hospital at 7 p.m. the whole thyroid gland, but especially the right lobe, was much enlarged, tense, and tender. There was likewise considerable general swelling of the neck and over the upper part of the sternum, and there was great œdema of the right side of the pharynx and larynx. The pharynx was scarified and the patient was much relieved by a morphine injection, rest in bed, and the external application of ice to the neck. The swelling gradually subsided. Eventually (March 17th) the man felt almost in his usual condition again, but the thyroid gland was somewhat enlarged, and the skin of the neck (especially the right side), and the upper front part of the chest was discoloured, as if from extensive bruising. The skin of these parts presented various shades of green, greenish-yellow, and purple, and there was still much ecchymosis of the mucous membrane of the pharynx and larynx.

Dr. **Forsyth** said that the anatomical structure of the thyroid gland made it improbable that a hæmorrhage occurring therein would produce symptoms such as those described. At present the gland had preserved its normal shape.

Dr. **Weber**, in reply, said that the gland had certainly been tense and swollen.

Mr. H. **Betham Robinson** showed a case of

ENLARGEMENT OF THE CLAVICLE AND LOWER JAW.

The patient was a boy, æt. 13, with chronic inflammatory swelling of right clavicle and left side of lower jaw, dating from a fall six months before. There was some nodular enlargement of right half of thyroid gland. There had been some reduction in size under potassium iodide.

Mr. **Tubby** remarked that he had once seen a growth, secondary to a thyroid tumour, situate in the clavicle.

Dr. **Harry Campbell** showed a case of

DISAPPEARANCE OF THE SUBCUTANEOUS FAT ABOVE THE REGION OF THE LOWER EXTREMITIES.

Girl, æt. 21. The disappearance especially marked in the face, chest, and abdomen, including the region of the *mons veneris*. There was no disappearance of fat from the mammary glands or the orbits. There was an abundant deposit of subcutaneous fat in the buttocks and lower extremities generally. The patient was said to have been perfectly normal up to the age of seven. From this time until the age of fourteen there occurred a gradual disappearance of fat from the affected regions.

Mr. **Clutton** compared the condition to morphœa.

Mr. **Donald Armour** showed a patient from whom

A LARGE POLYCYSTIC KIDNEY WAS REMOVED TWO AND A HALF YEARS AGO.

The patient was a woman, æt. 29; had been quite unaware of the tumour, and there were no urinary symptoms.

Dr. **Parkes Weber** wondered whether the opposite kidney was also cystic. He referred to a recent case in which a French surgeon had removed what he took to be a cystic kidney, but which proved at autopsy to be a polycystic pararenal growth of Wolffian origin.

Mr. **Armour**, in reply, said that there were no evidences of affection of the other kidney.

Mr. W. G. **Spencer** showed a case of

OBLITERATION OF BILATERAL PSOAS ABSCESS.

The patient, a woman, æt. 25, had recovered, apparently completely, after several operations.

Mr. **Warren Low** referred to the advantages of closing the wound after operation in such cases.

Mr. **Spencer**, in reply, said, that that was at first impossible in this case, as the sac was already septic when he first saw the case.

Mr. A. H. **Tubby** also showed a case of "Congenital Dislocation of the Hip."

Mr. A. E. J. **Barker** showed a case, in a woman, æt. 24, of "Fixation of the Jaw." The left masseter was fibrous.

ROYAL ACADEMY OF MEDICINE IN IRELAND

Section of Medicine.

Meeting held Friday, March 1st, 1907.

The President, J. M. Pedmond, R.C.P.I., in the Chair.

A CASE OF MANIACAL CHOREA.

The President of the Royal Academy (Dr. J. Magee Finny) read a paper on maniacal chorea, and based it on the clinical report of a case which had lasted nine days from the onset of the chorea, and which had been preceded by an attack of rheumatism of a fortnight's duration. The patient, a girl, æt. 17, was admitted to Sir Patrick Duns' Hospital on June 14th, 1906, with chorea minor, and presented a distinct systolic apical murmur. This murmur was audible up to her death, and was considered probably due to organic disease of the mitral valve. The day following her admission the choreic movements became very violent, and one or two nurses were necessary to keep her in bed and prevent self-injury. With the access of the muscular movements maniacal symptoms set in, and so greatly did they overshadow the motorial disturbance that the house surgeon was about to send the patient into the lunatic asylum, believing it to be a case of acute mania. The temperature was not raised for five days, but on the sixth it reached 103.4° for a few hours, and the pulse from 80 shot up to 130 on the day of her death. I never saw a human being so tossed about and agitated in every limb as this girl. The skin of her lips, back, arm, and legs was rubbed off from the violence and suddenness of the movements, as no appliances of wadding, bandages and stockings, &c., could be kept on; and at times it required four to eight persons to restrain her in bed. Calm was obtained—but very temporarily—by chloral inhalation of chloroform, and the hypodermic of hyoscin hydrobrom gr. 1-200 or 1-100. Death was preceded by semi-coma of six to eight hours' duration. Curious to say, all through (except for last day or two) intelligence was retained, and she could occasionally answer a question in a few words. At the autopsy, made by Dr. O'Sullivan, the brain showed very little gross alteration beyond engorgement of the vessels of the cortex, and there was an absence of meningeal inflammation of brain or cord. On microscopic examination some small vessels of the cortex in the Rolandic area were thrombosed; in others collections of cells with oval nuclei lay heaped up in the perivascular lymphatic spaces. The spinal cord presented nothing abnormal. The cerebro-spinal fluid was examined bacteriologically for Wassermann's coccus (*Diplococcus rheumaticus*), but with negative results. The cultures remained sterile. No other organ presented any abnormality, except the heart, which was small and in an atrophied condition. The mitral and other valves were not inflamed. He called particular attention to the agreement between *clinical observation* that rheumatism and chorea are due to the same poison, and the *recent bacteriological* work of Poynton and Holmes, which demonstrates that the diplococcus of rheumatism is present in the brain and membranes of the cord as well as in the fringe of vegetation around the mitral orifice and in the mitral valve itself—so commonly found in chorea and in rheumatism. Thus, the same micro-organism has been found in various organs —brain, spinal cord and heart. This organism, termed the "*Diplococcus rheumaticus*," has been found in rheumatism and in chorea, and the toxin produced by it in proportion as it attacks the psychical or the motorial centres of the human subject so the case will be one showing great mental disturbance (mania) or violent choreic muscular movements, or both.

Dr. J. Craig said that chorea had scarcely yet got its proper place in the text-books. Some few years ago it was described under the head of diseases of the articulations; now it was described, rightly, as a specific fever. Associated with the toxæmia produced by the micro-organism, there was always a certain amount of acute dilatation of the heart in the early stage, with a cardiac murmur that would subsequently disappear. The communication had tended to associate in their minds the great connection there was between chorea and rheumatism; he had shown that chorea was merely a complication or manifestation of the rheumatic state. In treating cases of chorea he had retracted considerably from his belief in the administration of large doses of arsenic.

Dr. Spencer Sheill recalled a communication of his dealing with two cases of chorea, both associated with pregnancy, one of which ceased when the uterus was emptied, and the other of which was perfectly described by Dr. Finny's case, with the exception that there was no rheumatic history. He regretted that in the latter case the autopsy was incomplete and unsatisfactory.

The President of the Academy, in replying, said if they were agreed that the poison of rheumatism and chorea were identical, and affected different parts of the body through the toxin, it would help very much to explain some otherwise very difficult phenomena of clinical experience; it would make them very cautious of making little of cases of chorea which came into hospital. Choreiform movement was only a small expression of a serious poison which was intoxicating the patient and injuring the nervous and muscular system.

MOVABLE SPLEEN, WITH ACCOUNT OF A CASE.

Dr. Moorhead read an account of a case of movable spleen. He also gave a *résumé* of the literature of the subject.

BRITISH GYNÆCOLOGICAL SOCIETY.

Meeting held March 14th, 1907.

Mr. W. D. Spanton, F.R.C.S., President, in the Chair.

Specimens.

The President exhibited specimens of

(1) Sarcoma of the parovarium.

(2) Myoma of uterus with sarcomatous outgrowth removed by abdominal hysterectomy.

(Which will be found on page 337).

Dr. J. A. Mansell Moullin exhibited a fibroid uterus containing a fœtus of four months, removed by sub-peritoneal hysterectomy. The patient was æt 26, and pregnant for the first time.

The diagnosis was somewhat obscure. The patient complained of great abdominal pain during the last few days, and the tenderness on examining the tumour suggested that the gestation might be ectopic.

A large fibroid developing in the cervical region, rendered the possibility of delivering at full time very doubtful.

Under the circumstances Dr. Mansell Moullin decided to remove the tumour at once instead of waiting until the fœtus was visible. No obvious cause for the pain and tenderness was found. The patient was doing well.

Dr. Heywood Smith considered the pain might be due to compression. Fibroids of the uterus situated in the pelvis gave more pain than those which rose above it. When such a tumour became jammed it did not necessarily follow that it was adherent.

Dr. J. A. Mansell Moullin said there was no compression of the tumour at all. Moreover there was no sign of peritonitis or degenerative change.

Mr. Bowreman Jessett, referring to the second specimen shown by the President, said the outgrowth was sarcomatous and the tumour itself was not. This was an interesting point, as he believed that cases of fibroid uterus became sarcomatous far more frequently than was supposed.

Mr. Alban Doran said they were absolutely uncertain about those quasi-malignant or semi-malignant or entirely malignant fibroids. In 1902 he removed a fibroid that looked very malignant, and a few months later another. Dr. Cuthbert Lockyer made out that endothelioma was invading the fibroid in either case. In one case the patient died within five months from recurrence. The other patient was now alive and perfectly well, and had not had a stormy menopause.

Dr. C. H. F. **ROUTH** said he thought great credit was due to men who had the courage to remove these tumours and obtain a recovery afterwards. In his opinion, however, one of the greatest questions to discuss was not so much the structure of tumours as how to prevent their growth. In connection with these myomatous tumours and how they became infected with carcinoma he heard it stated that no instance was recorded in which cancer ever invaded the ureters, though it might surround them. He thought that probably there was in the ureters a particular element which prevented their being attacked by cancer. If that were true, then by the use of a serum obtained from the ureters the disease might possibly be prevented or cured. He thought that this question of trying to provide such a serum was one which should be investigated.

Dr. **MACNAUGHTON-JONES** read notes on a specimen which he showed of

CARCINOMA OF THE VAGINA,

which will be found on page 335.

Dr. J. H. **DAUBER** said squamous epithelioma of the vulva was sometimes seen on both sides of the vulva as if one side had infected the other, and he wished to know if carcinoma of one side of the vagina infected the opposite one.

Dr. **ETHEL VAUGHAN** thought the growth was an endothelioma and not a carcinoma, judging both from the naked eye appearance and the microscopic appearance which she had just seen. One reason why she thought that the specimen was an endothelioma and not a carcinoma was that in some of those cell masses there were definite spaces lined with endothelium. The cells were rather angular and characteristic of endothelioma. Secondly, there was no small cell infiltration which was usually present in rapidly growing carcinoma of the vagina.

Dr. S. **JERVOIS AARONS** said that many fibroid tumours which appeared to be malignant were not so. On the other hand there were many tumours which looked like ordinary fibro-myoma, but were found to be sarcomatous.

The **PRESIDENT** said the more they heard about cases of simple sarcomatous tumours the more they had to come to the conclusion that a microscopical appearance *per se* was not authoritative. They must watch the clinical progress of such a case before they could come to a definite decision.

Mr. **ALBAN DORAN** asked if it was not the case that they might take what was normal for what was abnormal. In fibroids of the uterus there was an enormous number of blood vessels and spaces. Then again there was a great deal of endothelium about, and they might mistake what was not a new growth for what might be a new growth.

Dr. H. **BECKETT-OVERY** said he examined one case of carcinoma of the vagina associated with a very definite adenoma of the kidney.

Mr. J. H. **TARGETT** said that he thought the first tumour shown by Dr. Macnaughton-Jones was probably glandular carcinoma. They knew that the vagina had no glands, but possibly the tumour might have originated in an acinus of the vulvo vaginal glands. It might have had its origin in some gland connected with the ureter. There was one other possible source of origin. The patient had carcinoma of the ovary, which they did not know about till a long time afterwards. But she presented herself as a case of carcinoma of the vagina. It was thought to be primary to the vagina, but it was really secondary to growth in the ovary. Endothelioma was not an uncommon event. One was as young as 36, and at the time she was examined the rectum was already invaded by the disease. In the other case the endothelioma was removed, but after about two years there was a recurrence of the malady in the iliac glands.

Dr. **SMALLWOOD SAVAGE** said he had a case under his observation some two years ago of sarcoma of the vagina. It was one in which there was a friable growth in the lower third of the vagina on the posterior wall. The growth bled profusely, and he removed it as far as he could, but he saw at the time that its removal would not prove of any great value. The patient died not long after the operation. On microscopical examination he found the growth to be a small round-celled sarcoma.

Dr. H. **MACNAUGHTON-JONES**, in reply to the various criticisms passed on his first mentioned specimen said, it was really most difficult to say whether a growth in the ovary or in the vagina or in the uterus was really primary or not, until a certain time had elapsed. Mr. Targett had described the carcinoma as possibly of glandular origin. In the vagina there were columnar tubules which Dr. Lockyer had referred to in these growths. He would say that to Dr. Mary Dixon Jones, of New York, was due the credit of having been the first to describe endothelioma of the ovary over twenty-five years ago. He himself had seen specimens of it, and he would not have thought that there was any difficulty in recognising an endotheliomatous tumour. He did not know there was any case on record of primary carcinoma springing from both sides of the vagina. He proposed that the specimen should be referred to a Pathological Committee.

Mr. F. **BOWREMAN JESSETT** seconded the proposition which was unanimously agreed to.

Mr. **BOWREMAN JESSETT** read notes on a specimen of "Carcinoma of the Ovary involving the sigmoid flexure."

This will be found fully reported on page 334.

Mr. E. **STANMORE BISHOP** read a paper on

MOBILE KIDNEY,

with a description of an operation for anterior nephropexy.

Mr. **HURRY FENWICK** said he had had about 500 kidney cases. One of the greatest bugbears was the movable kidney. He had never been satisfactorily able to fix it. He had come to the conclusion that in many cases the symptoms were not due to the mere mobility of the organ, because they fixed movable kidneys sometimes extremely well and yet the symptoms continued. He had had to remove some of them, and after removal the pain had gone on, which was a severe indictment against fixing certain cases of movable kidney. When he had a case of movable kidney he usually advocated, as a palliative measure, the wearing of a belt. If a patient was suffering from frequency of micturition he generally fixed the kidney. He found out the value of picking off the anterior layer and fixing it over to the incision and stripping the whole of the posterior layer.

Dr. **PARSONS** remarked that bad cases of floating kidney did have symptoms, and it was astonishing how well some of them became after operative treatment. He was interested to hear this new method of operation, and thought it was a thoroughly scientific one.

Mr. **CHARLES RYALL** said that some years ago he did a great many operations for movable kidney. But a great many of those cases had been most disappointing. One had to be careful in recommending operation in cases of floating kidney because if the operation did not cure the patient the surgeon had better not attempt a second operation. He was convinced that only where there were definite grave kidney symptoms should it be fixed. The conditions where an operation was indicated were severe renal pain, hæmorrhage, intermittent hydronephrosis, and renal colic. He himself certainly preferred the posterior or lumbar incision for most of the kidney operations.

Mr. **CHRISTOPHER MARTIN** said he believed that in the great majority of cases the dropping of a kidney was not the cause of a neurasthenic condition, but the neurasthenic condition was the cause of the dropping of the kidney. With regard to treatment he never advised operation unless palliative measures had failed. He had tried the use of belts, but had not found them beneficial at all, excepting a double belt was employed. In cases requiring operation he generally used the posterior vertical incision. At the present time he had in his private hospital a patient from whom he removed a kidney which had been operated upon in London some two years ago by a London surgeon, who put the stitches right through the kidney substance. The patient had three big stones in her kidney, and one stone was around the end of the suture. So that he thought it was very bad surgery to put sutures through the kidney substance; they should only go through the capsules. He did not see the object of stripping off the capsule from the lower end of the kidney. The capsule would have to support the kidney, and that, of course, could not be if it was stripped off. The sutures that Mr. Bishop put through the kidney would help to hold it up. The capsule should be stripped off towards the upper end of the kidney, so as to get adhesion between the raw surface on the kidney and the fascia at the back.

Dr. **Macnaughton-Jones** would like to know what were the permanent results in that operation as compared with those of the usual posterior operation. At the same time they must make a beginning in anything, and the operation brought before them that night was distinctly a new departure and therefore ought to receive full consideration. As regards movable kidney, if any woman came to him with any disease below the ensiform cartilage, the first thing that he examined her for was movable kidney. It occurred in a large number of women. He entirely and totally disagreed with the view put forward by Sir Frederick Treves that operation for movable kidney was one which should be discarded and was not a scientific surgical procedure. He believed that the loss of fat and the want of support to the kidney had a great deal to say to movable kidney, as patients were kept in bed for several weeks, fed and massaged, and they got up with the kidney in its proper position in certain cases, and yet no operation had been done. Whilst he believed in operation he was equally confident that there were some cases which would disappoint them. He tried belts in cases where there was not complete dislocation of the kidney. He showed a belt which he had used for years and found most satisfactory. A woman with a movable kidney should be measured for it or its position and the support adjusted accordingly. He knew people with loose kidney who were using that belt at the present day and had never been operated on.

Dr. **Heywood Smith** said that an important factor in the production of movable kidney was tight lacing, and it would be instructive to compare the results observed in different countries whether it was injurious or not.

The **President** said it was a recognised fact that tight lacing had a good deal to do with movable kidney. He thought a protest ought to be made against ascribing symptoms of the most varied type to mobile or movable kidney, the latest being that of insanity.

Mr. **Bishop** replied to the various criticisms, and the meeting adjourned.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

Meeting held in the rooms of the Medical Society of London on Friday, March 15th.

Dr. G. A. **Sutherland**, in the Chair.

Mr. G. **Russell Howard** read a paper on

Tuberculosis of the testis in infants.

The condition, he remarked, is rarer in infants than in adults, the percentage compared to all surgical cases in the London Hospital during ten years being .07 per cent. in infants and .33 per cent in adults. The disease is primary in the epididymis and spreads to the body of the testis, while the resicular seminales and prostate are rarely affected in the early stage. It affects chiefly the left testis, and is rare in the undescended testis. Hydrocele occurs in a third of the cases. The diagnosis from syphilitic disease is difficult and chiefly rests on other evidence and the result of treatment. Tubercular peritonitis is a frequent complication. If only one testis be affected and general treatment be not successful the testis may be removed without bad effect on the mental and bodily growth; if both testis are diseased they must only be removed as a last resource, owing to the impairment of mental and bodily vigour produced by their ablation. Concluding notes on a case of biliary cirrhosis was read by T. E. Holmes.

A specimen of teratoma from the back of a child, æt. 6, was shown by J. Russell Howard. The tumour was 5 inches by 3 inches and extended from the upper part of the saccum to the tip of the coccyx. The upper part of the tumour consisted of a collection of small cysts and a quantity of vascular fibrous, fatty and cartilaginous tissue. Bone was also found. In the lower part of the tumour was a mass lying in a serous sac which was reflected round it. This mass was of the size and shape of an adult kidney with a semblance of a pelvis, but the microscopic examination showed none of the normal kidney structure. The tumour was evidently derived from all the three layers of the embryo, the ectoderm, mesoderm and endoderm, and therefore must be considered a teratoma.

A large abdominal tumour in a boy, æt. 3 years, was shown by Dr. Cantley. It was probably a congenital hydronephrosis.

He also showed a boy, æt. two years, with a large solid tumour in the left lower quadrant of the abdomen. The spleen and liver were somewhat enlarged. He regarded it as sarcomatous in character.

A case of central tumour in a girl, æt. 7 years, was shown by Dr. Porter Parkinson. There was a history of general convulsions on and off for eighteen months. Two months weakness of the right side of face and limbs. Latterly headache and vomiting had occurred. There was double optic neuritis. In one fit which had been observed the movements were chiefly of the right limbs. Dr. Parkinson considered that there was a subcostical tumour on the left side, probably gliomatous in nature, and he proposed to have the child trephined with the object of preserving the sight.

The case of multiple lupus vulgaris in a boy, æt. 10 years, was shown by Mr. G. Pernet. The patches which were on the chin and right shin followed an attack of measles. The disease had improved considerably by three months' treatment by X-rays, preceded by scraping.

Specimens of infective endocarditis was shown by Dr. Cantley, and of cirrhosis of the liver with obliteration of the bile ducts by Dr. Porter Parkinson.

Cases were also shown by Mr. Sydney Rumbolt, Mr. Milner Burgess and Dr. Sprigge.

CENTRAL MIDWIVES' BOARD.

Meeting held March 21.

The President, Dr. **Champneys**, in the Chair.

At the commencement of the meeting the President expressed his great regret that Dr. Dakin, owing to professional engagements, could no longer be on the Board. His help had been much appreciated. Dr. S. B. Atkinson, Barrister-at-Law, had been elected in his place.

The **Secretary** then read a letter from the Privy Council as to the Board's power to remove names from the Roll without allegations of misconduct—*i.e.*, when old or infirm.

The **President** said this was a power which had long been required. They had many such nurses on the list with old age, defects of hearing, seeing, &c.

It had been decided by the Standing Committee to refuse the application of the Leeds Maternity Hospital as a training centre, and on this being confirmed, Miss Paget proposed that some reason for refusal be given, in order that failures to meet requirements might be mended.

Mr. Parker Young answered he did not think it wise to give reasons. They were not obliged to, but it was agreed when, as in this case, the only reason being that the hospital was new, to request the Secretary to forward reasons for decision.

The following applications for teaching were granted: Mr. S. Craddock, of Bath, and Dr. G. M. Fox, but Miss Wilson rose to protest against the acceptance of some teachers when others had been waiting months and were equally well qualified. The acceptation was therefore postponed for re-decision, as the President considered it only fair to deal first with men who were in suspense.

With regard to the situation of the Board with the Privy Council Mr. Fordham will move at the next meeting that a sub-committee, consisting of the President, Mr. Fordham and Miss Paget prepare a statement concerning amendments to the 1902 Midwives' Act to be laid before the Council.

THE BOARD'S POSITION IN REGARD TO POOR-LAW INSTITUTION.

Mr. Parker Young then moved that question should be put to the President as to the exact position the Board stood in reference to training in Poor Law institutions. There had been many meetings *in camera*, but it was his opinion some explanation, even one for the public, should be given.

The President answered he was quite prepared to say how far matters had progressed and proceeded to do so on the points of matrons of Poor Law institutions signing certificates, compulsory notification of birth by midwives, &c., and points on which the Board did not yet see their way to agree to. The principal points are contained in a memorandum, an abstract of which is appended.

Before the meeting adjourned the Secretary asked if a special meeting could not be held for the hearing of penal cases? These were ever increasing, and there were now fifty waiting.

Abstract of Memorandum on the Course of Negotiations between the Privy Council and the Board on the subject of Training in Poor Law Institutions.

On May 9, 1906, the C.M.B. submitted their revised rules to the Privy Council for approval. Rule D 1 omits the special exceptions in favour of Poor Law Institutions contained in the present rule. These exceptions permit the matron or a superintendent nurse (being certified midwives) of a Poor Law institution to sign the certificates of attendance on cases and attendance during the lying-in period, without requiring the approval of the Board. Rule E 24 limits to certain specified cases the exemption of Poor Law institutions from the whole of Section E as conferred by the present rules.

On July 24, 1906, the Privy Council replied transmitting certain amendments "that are deemed necessary." These alteration transfers are the supervision of the course of training in a Poor Law institution from the Central Midwives' Board to the Local Government Board. They permit the duly appointed chief medical officer of a Poor Law institution to sign the certificate of instruction without requiring the approval of the Board. The Privy Council added that they thought that the existing exemption of Poor Law institutions from the whole of Section E should be maintained.

On October 4, 1906, the C.M.B. resolved that they "do not see their way to acquiescing in the amendments suggested by the Privy Council," and asking for a conference.

On January 24th, 1907, the Board amended Rule D 1 so as to authorise training in a Poor Law institution originally approved by them, where the Local Government Board declare the training to be carried on in conformity with the rules of the Central Midwives' Board. They accepted the duly appointed chief medical officer of a Poor Law institution as qualified to sign the certificate of instruction without requiring their approval. A new rule (E 25) was also framed exempting Poor Law institutions from the whole of Section E, with a note declaratory of an undertaking by the Local Government Board to carry out the rules of the Central Midwives' Board in institutions under their authority. The Board unanimously resolve that special treatment of Poor Law institutions would be detrimental to the efficient training of midwives.

On February 26th, 1907, the Privy Council replied transmitting the observations of the Local Government Board on the revised Rules. With regard to Rule D 1 the Local Government Board accept the approval of the Central Midwives' Board as a condition of the recognition of a Poor Law institution as a training school, provided the Central Midwives' Board "will consent to approve, for the purpose of this rule, every Poor Law institution the arrangements of which are certified by the Local Government Board to be satisfactory." With regard to Rule E 25 the Local Government Board object to the note binding them to carry out the rules of the Central Midwives' Board in institutions under their authority. The Lord President concurred with the Local Government Board on both the above points.

On March 8th, 1907, the C.M.B. resolved that they are unable to delegate the duties imposed upon them by the Act "to secure the better training of midwives," and regret that they are unable to give the Lord President their assurance of approval of "every Poor Law institution the arrangements of which are certified by the Local Government Board to be satisfactory." They also deleted the note to Rule E 25, objected to by the Local Government Board.

FRANCE.

Paris, March 23rd, 1907.

Asthma or Cardio-Sclerosis.

In text-books distinguishing certain characters separating true asthma from other forms of dyspnœa, such as uræmic, cardiac, pseudo-asthma, patients are frequently considered as asthmatic who suffer in reality from anything but true asthma, and this error may be attended with disastrous consequences, says Prof. Huchard.

To a toxic phenomenon is attributed a nervous affection. and a series of sedatives and anti-dyspnœic remedies are prescribed, adding their baneful action to the intoxication, the very cause of the trouble. The symptom is taken for the cause and alone treated. The patients' breathe with difficulty, consequently opium, belladonna, bromide of potassium are prescribed. To guard against the exhaustion produced by the attacks, a substantial regimen is advised. But the desired effect is not produced, on the contrary cardiac troubles set in and digitalis is prescribed. Thus the patients succumb more as victims of the treatment than of the malady.

However, a little attention would be sufficient to avoid the therapeutical error. Asthma is hardly ever a malady of advanced age. It is exceptional to find it for the first time after forty or fifty years of age. It is above all observed in adolescents or even in young children, in whom it is frequently overlooked, and yet asthma is distinctly hereditary.

Consequently each time that a patient of a certain age presents attacks of dyspnœa resembling asthma, and to which he was not previously subject, the cause must be sought for elsewhere. Prof. Huchard insists strongly on this fact. A patient, he says, does not become asthmatic at fifty or sixty years of age, he suffers rather from arterio-schlerosis, which provokes attacks of toxic alimentary dyspnœa resembling much true asthma. It is not the lung that is at fault, but the kidney (arterial tension, bruit de Galop, albuminuria, retention of chlorides).

The indications of treatment consequently are very simple :—Diminish the existing intoxication by diuretics (theobromin) drastic purgatives (tincture of jalap) blood letting or wet cupping. Prevent as much as possible a repetition of intoxication by placing the patient on a strict lacto-vegetarian diet, meat being absolutely prohibited. Under the influence of this treatment the condition of the patient improves very rapidly, giving him rest for many months.

ENTERO-COLITIS.

Muco-membranous colitis should not be considered as a malady, but as a clinical syndroma characterised by disorders bearing on the triple domain of the function of the large intestine—mobility, sensitiveness, and secretion. The affection is essentially constituted by abdominal pain, habitual spasmodic constipation with periodic diarrhœa and by the presence of mucous in the excretions. Concurrently exists also hyperæsthenic gastric dyspepsia with spasm of the pylorus and glanular hyper-secretion. The provoking cause of the dyspepsia is the irritation of the colic of the mucous membrane which in its turn is under the influence of the nerve supply irritated from some central cause (neurasthenia) or a peripheric cause where it, by a kind of mechanical reflex, as in certain lesions of the visceræ (uterus, kidneys, liver, etc.).

The medical treatment of the muco-membranous entero-colitis is not very complicated, and if the patient observes faithfully the prescription of his attendant he may be assured of success.

One of the main points lies in the regimen. During the attacks milk alone should be taken, but in the interval a mixed diet may be permitted to the exclusion of soups, pork, shell fish, game, hard eggs, omelettes, salads and all kinds of sauces and spices; pure wine, spirits, coffee, tea. Otherwise the food may be taken in quantities.

The patient, where possible, should spend a few weeks in the country and preferably in the mountains. Dry friction, or with lavender spirits, is useful in asthenic patients, while the warm bath or douche has a good sedative effect. Enemas should be used with caution, either with pure water or with water to which has been added bicarbonate of soda. Enemas of warm olive oil administered at night, where constipation exists, have a very salutary action on the intestine. Purgatives should not be abused ; castor oil in small doses (one or two teaspoonsful) should alone be tolerated. But small doses of belladonna given every day are frequently sufficient to regulate the bowels.

Ext. of belladonna, Powder of belladonna	āā gr. 1-5.

For one pill, to be taken at bed-time.

To relieve the pain during the attacks of colic a half a grain of cocaine might be given, or one of the following pills :—

Ext. of belladonna, gr. 1-10.
Ext. cannabis indica, gr. ½.
Ext. of hyosciamus, gr. ½.
Powder of valerian, q.s.

GERMANY.

Berlin, March 24th, 1907.

At the Medizinischi Gesellschaft Exc., v. Bergmann showed a young woman with

SARCOMA OF THE SKULL.

The tumour was very vascular and showed fluctuation in every part. There were no signs of central pressure, notwithstanding the size of the tumour. In another case, the preparation from which was shown, the tumour was extirpated. At the operation, in spite of the use of Esmarch's bandages and the great rapidity with which the operation was performed, the loss of blood was so great that the patient bled to death. In spite of this danger, there was really nothing else that could be done.

Hr. Muskat showed two cases of

ISCHIAS SCOLIOTICA.

In both cases the scoliosis arose through the sciatica, the degree of it was excessive, the spinal column being flexed and stiffened in that position. The treatment consisted of suspension, massage, exercise, and the wearing of a supporting corset. In this way, at least, the pain might be mitigated.

Hr. Davidsohn showed a woman, æt. 71, who, thirty years ago, was suddenly attacked with loss of breath and cardiac spasms, which even extended to the muscles of the face. After that she lost her speech for a long time. Then her speech returned in a jerking fashion, but from time to time she had her attacks of shortness of breath. These attacks came on now only when she exerted herself in talking, or was otherwise excited, or when the laryngoscope was being used. The voice was even now peculiarly hoarse. The internal organs were sound. So long as the breathing was quiet the laryngoscopic appearance was normal ; on phonation, however, spasm of the muscles of the fauces came on, the vocal cords lay so close together that nothing below could be seen at all. The case was one of spastic dyspnœa and aphonia, and the origin of all was hysteria. The question was whether in this case there was spasm of the glotins contraction or paralysis of the glottis dilators. The first supposition was the more likely to be the correct one, as the condition was entirely changed under narcosis.

Hr. Lassar showed two cases of

PERMANENT RECOVERY FROM CANCROID OF THE LIP

by means of Röentgen or Radium Rays. Both cases were still free from glandular swellings. They were treated three years ago, the parts had cicatrised, and there was no sign of recurrence.

CONTUSIONAL PNEUMONIA. (*a*)

Hr. Finbringer said that he had seen scarcely half a dozen cases, but he had passed about thirty "opinions" under the Acts. They were, of course, all very severe cases. He must emphasize one point, viz., the significance of the period between the injury and the commencement of the pneumonia. Stern, in his well-known book, gave from a few hours to three to four days. The speaker at first was in accord with this but he had now recognized that there might be a longer interval—five to six days. No time could be fixed as exception occurred as they also occurred in other infectious diseases. In rare cases the injury might furnish a soil suitable for the development of germs already present, but the interval must not be stretched too far. The condition under which he should be in favour of a longer interval would be some weakness on the part of the patient, especially some chest trouble during the period. Sometimes some contusional trouble lasted weeks before the pneumonia appeared, as in one of his cases, when there was an interval of eight weeks before the pneumonia developed.

Hr. Westenhoeffer said that the most important material for a decision lay in examination and not in the Acts. Laceration of the lungs with hæmorrhage was frequently predisposed to by already existing disease of the vessels. The medical expert could not give a decision, we could only place the authorities in a position to give one.

Hr. Plehn said there was not much difference between injuries to the lungs from overstrain of direct violence. With a closed glottis and compression of the throat considerable lesions might take place.

Hr. Stadelmann, in forming a judgment of cases, always found himself on uncertain ground, so much was left over for subjective estimation. Different people thought differently. The length of time between the injury and the pneumonia was of the greatest importance. The ten days given by Litten could not be accepted as a rule. The individual case must be considered in the light of the sequence of events followed, and if the continuity could not be strictly proved, no decisive judgment could be given. But even after

---

(*a*) Discussion on Hr. Litten s Paper, March 4th.

a still longer period, a continuity might be proved as in Finbringer's case. A second question was how soon could a pneumonia develope on a contusion. There might be coincidence to time without there being any connection between the two. This was seen not infrequently in drunkards, who sometimes wandered about or worked whilst suffering from the disease. A man was carrying a heavy beam of wood on his back; he felt pain in his left side, and on the eleventh day after the accident died of pneumonia. He therefore had pneumonia whilst at work, and it was made worse by the injury.

Hr. Keans thought it best to take a stand midway between Westenhœffer's "Skeptizismus" and Litten's "Optimismus." Compression of the thorax might cause hæmorrhage, as was seen in the case of youthful healthy epileptics who, from their attack, had hæmorrhage in the neck and from the lungs. In this case mentioned by Litten, in which V. Leydon and Kraus had delivered "opinion," he could even now give no decisive judgment, he could only concede the probability of a connection between the trauma and the pneumonia.

Hr. Litten, in reply, did not know why he should be accused of optimism. He had only stated that in proper cases a connection between the trauma and the pneumonia should be conceded, and for this the physician was a more proper judge than the lawyer. When pneumonia was diagnosed only a few hours after the accident, it was probable, but it already existed before the injury was inflicted.

AUSTRIA.

Vienna, March 24th, 1907.

Multiple Fungoid Swellings.

At the "Gesellschaft" Goldreich showed an infant, 7 weeks old, with fungoid swellings over the joints, which appeared to be of a hereditary character. Over the twelfth dorsal vertebra a soft livid-coloured swelling about the size of a five shilling piece formed a "cold abscess." The right leg was œdematous; over the instep of the right foot a similar abscess had formed and was discharging serous pus. Over the malleolus medialis another livid fluctuating tumour was present, while the third, tce, of the left foot had another boggy swelling.

Such a state of affairs in a 7-weeks' child forced us to conclude that the primary cause was tubercle as Baumgarten had pointed out some time ago in a monograph on intrauterine tuberculosis, wherein he pointed out that the infecting tubercle bacilli must be transmitted to the germ in utero. This condition is certainly rare and possible only in a latent stage of the disease. This opinion is supported by the seat of the disease being situated on the fœtus most distant from extrauterine infection, viz., the legs and lower part of the spine.

Facial Asymmetry.

Rie showed a child with progressive hemiatrophy of the left side of the face, which he said was unusual inasmuch as the process was an inhibition or arrest of growth after birth. The right side had all the convexity of a child of its age, but the left was infantile from the left side of the nose over the same side of the head. The zygoma and bony portion of the left side, even the teeth, with the ear, were equally arrested in growth.

This asymmetry he affirmed was central, although the sensibility and motility were normal. The child was brought to hospital on account of chorea and for this defect. In discussing the aetiology he was firmly of opinion that only two causes were reasonable, viz., primary cerebral aggenesia, or an intra uterine lesion of a mechanical nature such as an ammotic band.

Neurath thought the difference in the sides of the head did not amount to more than a dysplasia. If we accept of the larger side as normal, the lesser may be accepted as a partial atrophy, or the opposite may be accepted making the right slightly hypertrophic, which frequently occurs in other parts of the body. and is everywhere borne out by testimony often repeated in medical literature. The extremities frequently suffer from this dysplasia.

Rie thought this opinion could not be supported in this case, as the asymmetry was so general, even the half of the tongue, teeth, and jaws were involved—not one single member as Neurath suggests.

Gall Stones.

Bakes gave the members a long account of the spontaneous fracture of gall stones in the gall bladder. In many operations he has found stones recently fractured, but whether this has been done by chemical or mechanical means he would not venture to say. He showed a gall bladder with stones taken from a patient which could be easily broken by pressing the bladder. This friable condition was not confined to the gall bladder, but was often met with in the urinary bladder as well.

He also recounted the history of a recurring gall stone in the bladder. A female, æt. 38, came to him suffering from cholecystitis hæmorrhagica, for which he operated on the 23rd of January, 1906. The gall bladder was found to have a normal calibre, which was opened and the bladder sounded. A few concretions and gall stones were found, that were easily removed, and the whole carefully washed out.

She recovered speedily, and remained perfectly well till January in the present year, when all the typical symptoms of cholelithiasis recurred. The pain was so excessive that another operation was inevitable. After narcotising with ether and opening the gall bladder, a number of small stones and a few larger ones about the size of hazel nuts with four other concretions were found blocking up the canal. His object in bringing this case forward was his conviction that this was a genuine recurring case. He suspected this in others he had operated, but always supposed he had left a nidus that provoked recurrence. In this case he was perfectly convinced that no concretion or any part of a concretion was left in the first operation.

He related an idiopathic retention cyst he met with in the gall duct of another case, where an anomaly of the valve in the canal existed. It was a congenital malformation, and the first he knew of that had been successfully treated by operative means or by performing chole-duodenostomy.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

BELFAST.

Belfast Ophthalmic Hospital.—The annual meeting of this hospital was held last week, the President of the Hospital, the Earl of Shaftesbury, K.C.V.O. in the chair. The medical report was read by Dr. Cecil Shaw, and spoken to by Dr. Walton Browne. It showed an increased number of patients, both in extern and intern departments, the former numbering 2,246, and the latter 174, while the total visits numbered 7,011. An appeal was made by Dr. Cecil Shaw for the sum of £250 or £300 for renovating the extern department, and Dr. Walton Browne in supporting this appeal said that he had a promise of £50 to start with. Lord Shaftesbury very generously offered another £50, and expressed the hope that the balance would soon be raised.

A Curious Poisoning Case.—At an inquest held near Portadown last week some curious facts transpired concerning the drinking habits of the deceased, a labourer, 45 years of age. He had been in the habit for the past twelve years of drinking methylated spirit, which he mixed with tea, and for some weeks seemed to have drunk this mixture constantly, with the result that he was found dead by his wife on Sunday morning, lying in the kitchen, where she had left him asleep on Saturday night. The verdict was death from excessive use, and an overdose of methylated spirits. Ether drinking is a recognised form of dissipation in parts of Counties Antrim and Derry, but methylated spirit has not yet been recognised as a popular drink.

The Health Commission.—Owing to the Assizes being on the Commission did not sit this week as had been intended. They held one evening sitting to allow members of the working classes who might wish to give evidence to appear. but only two persons came forward, and their evidence was not of much general interest. Next week the morning sittings will be resumed, and some important medical evidence is expected.

Cerebro-spinal Meningitis.—The epidemic of this disease continues to spread slowly, a few new cases occurring each day last week. The total number of cases in Belfast now reaches 207, with 110 deaths. There have also been a good many cases in the smaller towns of Ulster and in the surrounding country districts. In Lurgan, for instance, there have been five cases, two of which have proved fatal.

Nothing more has been heard of the serum treatment, the material for which was procured from Switzerland, and it is to be presumed that it has not proved a success.

Ulster Eye, Ear and Throat Hospital.—The annual meeting of this Hospital was held last week, being presided over by the Lord Mayor, the Earl of Shaftesbury, K.C.V.O. The report showed that 2,170 new cases had been seen in the extern department, and 340 treated in the wards, of whom 38 were private patients. The late Dr. McKeown advocated this system of having a certain number of private wards in the hospital, and his successors, Drs. Killen and Allen adhere to it, though most of the Belfast surgeons prefer to send private patients to some of the many private hospitals or nursing homes. It is one of those questions which admit of a good deal being said on both sides. for there certainly is a class of patients who can pay enough to repay the hospital for their keep and nursing, but not enough to yield a profit to the proprietor of a nursing home.

LETTERS TO THE EDITOR.

THE PALL MALL GAZETTE ON INSANITY.

To the Editor of The Medical Press and Circular.

Dear Sir,—The notice in the *Pall Mall Gazette* took me by surprise, but I thought that the wording of it was quite sufficient to indicate that I had nothing to do with it. It is the journalistic tendency of the age to create " sensations," hence any apparent novelty is seized upon, and it is for the Ethical Committee of the British Medical Association to consider what steps can be taken to prevent such occurrences.—I am, Sir, yours faithfully,

Bernard Hollander.

THE DEATH OF DOWIE.

To the Editor of the Medical Press and Circular.

Sir,—The papers of last week announced the death of Dowie, the self-proclaimed " Divinely commissioned First Apostle of the Church "—to use the least blasphemous of his titles—the founder of Zion city on Lake Michigan. and the renowned wholesale medical miracle monger. If ever there were cases in which the usually respected maxim " de martriss se " should be set aside they must be those in which blatant impostors like Dowie end their career. Dowie was the most prominent among the army of pretenders who find an inexhaustible field for their enterprises in the United States ; and we may be certain that so long as the game continues profitable, successors capable of working on a similarly large scale, if not in the same position, will always be forthcoming. If men of Dowie's pretensions led lives of poverty and self-sacrifice they might be chargeable only with religious fanaticism, but there exists always an easily discoverable sordid side to their lives which makes plain the true aim of their performances. The exposure in Dowie's case which led to his downfall and death proved, among other amazing things, that since 1899 he had used $84,000 a year for his personal expenses, and that these expenses were incurred in extravagant living, and in " the teaching of polygamy." The interesting questions for the psychologist and the sociologist—questions I should much like to see fully discussed in your paper— seem to me how to account for the gross credulity of masses of the people at this period of the twentieth century in a nation supposed to stand in the very front of civilisation and enlightenment. Grotesque forms of theological and medical quackery flourish more in the United States than among any other people of European blood ; nowhere are there to be found multitudes so ready to subject themselves to, and sacrifice themselves for, impostors who will not stand the superficial scrutiny of the average man of the world, much less the scientific tests that might be so easily applied to them. The sale of quack medicines (the belief in which is hardly less gross than the old belief in witchcraft) is vastly greater in the United States than in these Islands, enormous as this is, yet the Americans have the best school education in the world. They have what ought to be the best character education through the strenuousness of the natural life, and the necessity for every citizen to be able to take care of himself if he is to remain erect in the struggling crowd. The enormous scale on which schemes of imposture are worked, often under the mask of religion and the cloak of hypocrisy is suggestively referred to in Mr. Wells's recent book " The Future in America." What do these things all mean as phenomena in the process of evolution (or is its decay) which we are witnessing among all the leading nations of our time ?

I am, sir, yours truly,

A Student of Psychology.

March 15th, 1907.

POLITICIANS AND ANTI-SCIENTIFIC FANATICISM.

To the Editor of the Medical Press and Circular.

Sir,—At a large meeting of the Liberal Party in this district last week Mr. W. Tebb was to have taken the chair. In a letter excusing his absence the following was the most important passage :—" I should like to have said a few words on two burning questions—the twin monsters, vivisection, with its unspeakable tortures of animals in the name of science, and the other the State blood-poisoning of helpless and defenceless children, known as vaccination. High authorities maintain that no benefit has ever come of vivisection, and the evidence of all trustworthy statistics show that vaccination is no preventive of smallpox. In the epidemic of 1871 the *Lancet* reported ten thousand deaths and 122,000 cases of smallpox amongst the vaccinated. Here were 122,000 failures ! At the same time it must not be forgotten, as proved before the Royal Vaccination Commission that vaccination has often been attended with the inoculation of repulsive and incurable diseases. No amendment of the law will render it tolerable. It must be swept from the Statute Book." The reading of this letter was " punctuated with applause." Mr. Harry Brodie, the member for the Reigate Division, then delivered a lengthy address in which he dealt with every prominent question of the day with the exception of the two broached by Mr. Tebb. These he passed over in complete silence. The inference is that Mr. Brodie does not sympathise with the grotesque utterances of his fanatical supporters, but has not the courage to express his opinions. He is afraid to lose a few votes, and gives tacit support to views which very probably are odious to him. In a constituency of upwards of 15,000 electors Mr Brodie won the seat by some 30 votes only. If he imagines that his attitude on the questions I refer to is likely to increase his slender majority I fancy he may be disappointed at the next election. I enclose my card.

I am, sir, yours truly,

A Surrey Doctor.

Near Reigate, March 15th, 1907.

SHOULD RAYNER BE EXECUTED?

To the Editor of The Medical Press and Circular.

Sir,—In common I hope, with many other medical men who believe that we are approaching a more scientific and a more humane ideal in the treatment of criminals, I was surprised and shocked to read the words addressed by the Lord Chief Justice to the unfortunate Horace George Rayner, when the jury returned the verdict of "Guilty." His lordship said that he could hold out no hope of reprieve; words of ominous significance, and words which in his judicial capacity he had no right to utter. The quality of mercy is one to be exercised by the people of this country through their elected representatives, and it is a cruel and shameful thing that the Lord Chief Justice should allow his great position to prejudice opinion in a matter of life and death, even if the victim is an unimportant unit in the great mass of humanity. And what of this unfortunate victim? What has he done that he should be coldly and deliberately executed? What chance has he ever had of becoming a decent citizen? An illegitimate child, the offspring of the sportive lust of a rich man who disputes his paternity and an alcoholic mother, brought up in a coterie of harlots and in an atmosphere of vice, flung into the world without position or principle, and left to fend for himself—what chance has such a one to acquire the bearing and moral ideas of civilised man? His heredity was nearly as bad as it could be, there was a strong alcoholic taint in his mother's family, and it is a matter of doubt whether his maternal grandfather did not destroy himself. His environmental influences were likewise execrable, and his mind had early been set against the rich tradesman who gave up a wife's love to seduce his employée. The lad was reduced by bad luck and adverse circumstance to a state of depression, which bordered on, if it did not cross the line of insanity, and in his desperate state, determined on self-destruction, he was sneered at by the very man of all others whom he believed he had the greatest claim on. If he had succeeded in killing himself, there is no doubt that the coroner's jury would have pronounced him temporarily insane, as so, Sir, he undoubtedly was. As his intention was frustrated by chance, he is considered fit to be the object of a society sensation—and in a thronged court he is coldly sentenced to death for becoming in a mad moment the instrument of death to a dissolute millionaire. Can you, Sir, not do anything to rouse your readers to put the scientific aspect of his case before the Home Secretary?

I am, yours truly,
M.D., D.P.H.

THE MENTAL CONDITION OF "DR. DOWIE."

To the Editor of The Medical Press and Circular.

Sir,—There can be no doubt, I think, that this remarkable case of mental aberration to which you so pertinently refer, would be regarded by the majority, if not all, lunacy experts as one of those unfortunate instances of genius and insanity at play in the same mind, and which agitate and administer to the weaknesses of common humanity. When criminal or moral perversion strongly taints a mind such as the deceased appeared to possess, the prejudices of the general community become so inflamed and exasperated, except such as bestowed by the veritable dupes themselves, that all commisseration is absorbed in emotions of recrimination and indignation (*De mortins nil nisi bonum*). Nevertheless a case of this character affords to the psychist and alienist, if not to the theologian, hints which the world at large can ill afford to lose sight of, because we see how easily the public mind even at the present hour is betrayed and readily falls a victim and prey to fanaticism, be it in any shape or form, whether such find vent in Welsh revivals, spiritualism, Christian science, the "New Theology," and may be tossed about by any other conceivable wind or doctrine. It cannot therefore be wondered that they are amongst the community, and it is an open secret that the majority of our profession represent those who possess minds which insist upon definite and coherent thought, urging that this can only be attained through the medium of the special senses, beyond which physical science and human capacity does not venture to encroach. Such as these regard all extraneous ideas as spurious, relegating all other ideas to the region of poetry and imagination.

I am, Sir, yours truly,
Clement H. Sers.

Brighton, March 23rd, 1907.

OBITUARY.

HENRY ST. JOHN BROOKS, M.D., D.Sc. (Dublin).

It was probably with a feeling of surprise that many to whom his name was familiar fifteen years ago read of the death last week of Henry St. John Brooks. He had lived of late years in such complete retirement, except for a small circle of friends, and had so completely severed himself from his scientific work, that he seemed almost of a past generation.

A native of South Africa, Brooks was educated at Trinity College, Dublin, where he had a distinguished undergraduate career, culminating in a Senior Moderatorship and Gold Medal in Natural Science in 1881. A pupil of Professor Macalister's, he soon became Chief Demonstrator of anatomy, and for the next ten years he devoted all his time to that branch of service. As an anatomist he combined in an unusual degree an enthusiasm for accurate detail learnt from Macalister, and an interest in comparative anatomy at that time somewhat uncommon. As a teacher he had the gift of inspiring keen interest in his subject, and his pupils learnt from him the great importance of thorough work. During this period he made many contributions to knowledge, of which perhaps the most important were those bearing on the minute distribution of nerves in the hand. He also wrote the chapter on the Nervous System for the first edition of Morris' *Anatomy*. In 1891, on the death of Dr. Thomas Little, he succeeded to the post of University Anatomist, which at that time combined duties in the dissecting room with surgical work in Sir Patrick Dun's Hospital. The clinical part of his work proved, as his friends expected, uncongenial, and a few years showed him that he had undertaken work for which he was unfitted. His health at the same time giving reason for anxiety, he determined on going to Australia, where for some years he worked in general practice. Unfortunately, his health became worse, and some six or seven years ago necessitated his complete withdrawal from active work. He therefore returned to Ireland, spending his time since in the study of languages, for which he had a marked aptitude.

There is no doubt that had fortune been kinder, Brooks would have obtained first rank as an anatomist. His gifts were for original research, and the necessity which forced him to undertake surgical work, blocked his career. As a teacher he is still kindly remembered in Dublin, and not a few Trinity men throughout the world remember with gratitude the ready help given them by a keen man of science at the outset of their medical career.

SPECIAL ARTICLE

THE UNIVERSITY QUESTION IN IRELAND.

A series of meetings have been held during the past week at most, if not at all of which, resolutions opposing the present scheme of the Government were adopted. The most important of these meetings was held in Trinity College on Friday last, and consisted of the graduates of the University. Owing to the very large numbers of graduates who attended, the meeting was divided into two sections, one of which occupied the Examination Hall, the other the Dining Hall.

The principal speakers were the Provost, the Right Hon. James H. Campbell, K.C., M.P.; the Right Hon. Sir E. Carson, K.C., M.P.,; the Bishops of Ossory and Derry, Lord Iveagh, Lord Ashbourne, Sir James Henderson, and the Rev. Dr. Prenter.

The following resolutions were unanimously adopted at both meetings, and copies were ordered to be sent to the Prime Minister, the Chief Secretary, and other members of the Cabinet:—

"That this meeting protests against the scheme put forward by Mr. Bryce in his speech of January 25th, 1907, as a grievous injustice to this University, and disastrous to the best interests of higher education in Ireland."

"That the prestige of the University of Dublin would not survive a process which abolishes the old University of 300 years, and transfers its name to a new and different institution."

"That the enforced alliance, within the same University, of Trinity College and a College specially designed for Roman Catholics, would be followed by sectarian strife, and must entail serious limitation to liberal education and free inquiry, not only in the University, but in Trinity College, the educational ideals of the two Colleges being incompatible."

The Provost who presided at the principal meeting in the Examination Hall announced that 3,866 graduates had signed a protest against Mr. Bryce's scheme. He also referred to a number of distinguished men who had also protested, and amongst these he mentioned Lord Kelvin, Sir William Crookes, Sir William Ramsay, Sir Archibald Geikie, Sir Joseph Hooker, Sir William Turner, Professor Bonney, Sir James Dewar, and Sir Robert Ball. He also stated that "resolutions, memorials, and protests on our behalf against any proposals which would hamper our teaching or destroy our autonomy have been extensively signed in Oxford, Cambridge, Manchester, Liverpool, Birmingham, and other English universities, the Scottish Universities, and the University of Wales. In five days since the protest was distributed, 127 signatures of Fellows of the Royal Society have been received, in addition to many letters of sympathy from Fellows, who are precluded by their relations with the Government from signing. A large additional number of Fellows have also signed in connection with academic protests."

Want of space prevents us from reporting at any length the remarks of the different speakers, but the following extract from the speech of Sir Edward Carson seems to us to place the case for Trinity College in the clearest light and with the strictest fairness to the claims for Catholics, which have been made on behalf of University Education for Roman Catholics in Ireland, that we believe it will be of interest to our readers. After referring at some length to the proposal of the Government, Sir Edward Carson continued:—

"Who has asked for this solution? I have gone through the evidence given before the Commission, and so far as I can see I can only find this solution, suggested by one single witness. And he was a noble lord, who never was at a University, and who prefaced his evidence by saying that he thought it right to say he approached the matter from a political rather than an academic point of view. The Presbyterians don't ask for it, the Methodists don't ask for it; Dr. Delany, the President of the University College, doesn't ask for it; on the contrary, he pointed out it was impossible. Nobody, so far as I know, asked for it in his evidence before the Commission, and certainly the demands put forward were of a far different character. To what then, do we owe this extraordinary evolution of the University question in Ireland? For what are we asked to do this? Not only are we asked to make concession to our Roman Catholic fellow-countrymen of endowing for them a separate establishment suitable to their needs, to which most of us, if not all of us, are willing to accede, but in addition to that, we are asked, to add to the difficulty, by mortally wounding the one institution in Ireland, of which every man, no matter what his religious or political views, is proud.

"I make an appeal solemnly to His Majesty's Government. A golden opportunity exists at the present moment for a settlement of this question. Not often has there been an occasion upon which so many minds differing to such an extreme extent have come together in a desire to appease those from whom they differ. Are the Government going to grasp the opportunity or are they bent on persisting in a course which, whatever the result, must lead to bitterness and sectarian strife, and at the end the ruin of this University by the success of the Government policy. And what out of that will arise for Ireland? Bitterness, hatred, all uncharitableness. Whereas, upon the other solution you may have a send off for education, which may lead to heights and delights for our country far away and above and beyond what any of us even dreamed of—a solution to which we will all give a willing accord, in which we will all, I think, unanimously join. If the Government adopt one and not the other, upon the head of the Government be the failure of their policy."

In the House of Commons on the 20th inst., Mr. Birrell, in answer to Mr. Sloan, said that he was not at present in a position to name a date for the introduction of legislation upon the subject of University Education in Ireland.

NEW BOOKS AND NEW EDITIONS.

The following have been received for review since the publication of our last monthly list:—

Sidney Appleton (London).
- Tics and Their Treatment. By Henry Meige and E. Feindel. With a Preface by Professor Brissaud. Translated and Edited by S. A. R. Wilson, M.A., M.B., B.Sc. Pp. 386. Price 9s. net.

J. B. Bailliere et Fils (Paris).
- Formulaire des Médicaments Nerveux. Pour 1907. Par H. Bocquillon-Limousin. P. 328.

Bailliere, Tindall and Cox. (London).
- The Röntgen Rays in Medical Work. By David Walsh, M.D.Ed. Part I.—The Electrical Apparatus. By H. Lewis Jones, M.D. F.R.C.P. Part II.—Medical and Surgical. By the Author. Fourth Edition, Illustrated. Pp. 433. Price 15s. net.
- Cancer: Its Treatment by Modern Methods. Being the Bradshaw Lecture for 1906. By Edmund Owen, Hon. LL.D., Aberdeen. Pp. 31. Price 1s. net.
- Antiseptic Methods for Surgical Nurses and Dressers. By Harold Upcott, F.R.C.S. Illustrated. Pp. 51. Price 2s. 6d. net.
- The Prevention of Cancer. By C. B. Keetley, F.R.C.S. Pp. 38 Price 1s. net.
- Aids to the Diagnosis and Treatment of Diseases of Children. By John McCaw, M.D., &c. Third Edition. Pp. 383. Price 4s. 6d. cloth; 4s. paper.
- Organic and Functional Nervous Diseases. By M. Allen Starr, M.D., Ph.D., &c., &c. Second Edition, thoroughly Revised and Illustrated. Pp. 816. Price 25s. net.

John Bale, Sons, and Danielsson, Ltd. (London).
- The Past, Present, and Future of the School for Advanced Medical Studies of University College, London. By Rickman John Godlee. Pp. 46. Price 2s. 6d. net.

Cassell and Co., Ltd. (London).
- Elements of Physics for Medical Students. By Frederic James M. Page, B.Sc. Illustrated. Pp. 288. Price 5s.

J. & A. Churchill (London).
- The Need, Objects, and Method of the Medical Inspection of Primary Schools. By Ralph H. Crowley, M.D. Pp. 24. Price 1s. net
- The Refraction of the Eye. A Manual for Students. By Gustavus Hartridge, F.R.C.S. Fourteenth Edition. Illustrated. Pp. 273 Price 5s. net.

Henry Kimpton (London).
- A Treatise on Orthopædic Surgery. By Royal Whitman, M.D. Third Edition, Revised, Enlarged and Illustrated. Pp. 871. Price 28s. net.
- Degeneration in Families: Observations in a Lunatic Asylum. By Fr. Lange, M.D. Authorized Translation from the Danish by C. Chr. Sonne. Pp. 207. Price 3s. 6d. net.

H. K. Lewis (London).
- Anæsthetics: Their Uses and Administrations. By Dudley Wilmot Buxton, M.D., B.S. Fourth Edition. Pp. 415. Price 7s. 6d.

J. B. Lippincott Co. (London).
- International Clinics: A Quarterly. Edited by A. O. J. Kelly, A.M., M.D. Vol. 4, Sixteenth Series, 1906. Pp. 322.

Longmans, Green and Co. (London).
- Notes on the Care of Babies and Young Children. By Blanche Tucker. With an Introduction by Dr. Hope, M.O.H. for Liverpool. Pp. 68. Price 1s.
- The Essentials of Histology for the Use of Students. By E. A. Schäfer, LL.D., Sc.D., F.R.S. Seventh Edition, Illustrated Pp. 507. Price 10s. 6d. net

Macmillan and Co., Ltd. (London).
- A System of Medicine by Many Writers. Edited by T. Clifford Allbutt, M.A., M.D., &c., &c., and H. D. Rolleston, M.A., M.D., F.R.C.P. Vol. II., Part 2.—Tropical Diseases and Animal Parasites. Illustrated. Pp. 1,055. Price 25s. net.

Some Points in the Surgery of the Brain and Its Membranes. By Charles A. Ballance, M.V.O., M.S., F.R.C.S Illustrated. Pp. 405. Price 15s. net.

Methuen and Co. (London).

The Drink Problem in its Medico-Sociological Aspects. By Fourteen Medical Authorities. Edited by T. N. Kelynack, M.D., M.R.C.P. Pp. 300. Price 7s. 6d. net.

The Evolution of Life. By H. Charlton Bastian, M.A., M.D., F.R.S. Illustrated. Pp. 319. Price 7s. 6d. net.

James Nisbet and Co., Ltd. (London).

Gall Stones and Diseases of the Bile-Ducts. By J. Bland-Sutton F.R.C.S.Eng. Illustrated. Pp. 233. Price 3s. 6d. net.

Young J. Pentland (Edinburgh).

The Diagnosis and Treatment of Intussusception. By Charles P. B. Clubbe. Pp. 92. Price 3s. 6d. net.

Rebman, Ltd. (London).

Monism: Thoughts Suggested by Professor Heackel's book, "The Riddle of the Universe." By S. Ph. Marcus, M.D., Translated by R. W. Filkin, M.D., F.R.S.E., &c. Pp. 144. Price 1s. net.

W. B. Saunders and Co. (London).

The Elements of the Science of Nutrition. By Graham Lush, Ph.D., M.A., F.R.S.Edin. Illustrated. Pp. 326. Price 12s. net.

A Manual of Pathology. By Guthrie McConnell, M.D. Illustrated. Pp. 523. Price 10s. net.

The Immediate Care of the Injured. By Albert S. Morrow, A.B., M.D. Illustrated. Pp. 340. Price 12s. net.

Atlas and Text-Book of Human Anatomy. By Dr. Johannes Sobotta. Edited with additions by J. Playfair McMurrich, A.M., Ph.D. Vol. II.—The Viscera, including the Heart. Illustrated. Pp. 194. Price 25s. net.

The Scientific Press, Ltd. (London).

The Care and Nursing of the Insane. By Percy J. Baily, M.B., C.M.Ed. Part I. Pp. 97. Price 1s. net.

Skin Diseases: Their Nursing and General Management. By G. Norman Meachen, M.D., B.S., &c., &c. Pp. 134. Price 2s. 6d. net.

A Manual for Nurses, on Abdominal Surgery, by Harold Burrows, M.B., F.R.C.S., Pp. 142. Price 2s. 6d. net.

Smith, Elder and Co. (London).

Saint Bartholomew's Hospital Reports. Edited by A. E. Garrod, M.D., and W. McAdam Eccles, M.S., F.R.C.S. Vol. 42. Pp. 463.

Elliot Stock (London).

The Functions of Food in the Body. By A. Rabagliati, M.A., M.D. Pp. 46. Price 1s. net.

John Wright and Co. (Bristol).

The Medical Annual: A Year-Book of Treatment and Practitioner's Index, 1907. Pp. 863. Price 7s. 6d. net.

The Year Book Publishers (Chicago).

The Practical Medicine Series. Edited by Gustavus P. Head, M.D. Vol. X.—Skin and Venereal Diseases, Nervous and Mental Diseases. Edited by W. L. Baum, M.D., Hugh T. Patrick, M.D., and Wm. Healy, A.B., M.D. Pp. 254.

REVIEWS OF BOOKS.

THE CHLOROFORM PROBLEM. (*a*)

Ever since Simpson demonstrated the anæsthetic properties of chloroform, just sixty years ago, this problem has been a fruitful source of discussion among medical writers. The aspect of the question has changed from time to time, but to this day the problem awaits solution. In the past the chief discussion was as to the relative merits of ether and chloroform as anæsthetic agents, and resulted in a compromise, each drug being granted its own sphere of usefulness. Recently the problem has assumed a form from which one may expect more instructive results, for workers are now endeavouring to establish the physiological properties of the drug and the proper method for its administration. In regard to the physiological action of almost any drug, there is still much to learn, and though one may regret, one should not complain because our knowledge is not complete. With chloroform, however, the case is somewhat different, for the anæsthetist who wishes for or seeks for a good working hypothesis as to the physiological action of this drug is at once met with a mass of conflicting statements, some of which, even when dealing with the most fundamental points, are directly contradictory of each other, though each appears to be vested with a reliable authority. If we take as an example the action of the drug on the heart, we are told by such respectable authorities as Gaskell, Shore, and Hill that chloroform has a direct paralysing influence on the heart and blood-vessels, while others assure us that chloroform has not been proved to act directly on the heart. Similar contradictions may be found between other statements concerning the physiological action of the drug and it is not to be wondered at if clinical anæsthetists sometimes look with grave suspicion on the statements of physiologists. Dr. Gill proposes in the volumes before use to examine the problem afresh from the clinical standpoint and using for his examination a strict logical analysis.

In the investigation of the phenomena attending the administration of chloroform three distinct actions of the drug may be recognised and must be differentiated. These three actions are its negative, its physical and its physiological action respectively. Chloroform vapour displaces air and consequently interferes with the function of aeration; this is its negative action. When present in excess in the airway its weight opposes abnormal resistance to the muscles of expiration; this is its physical action. When absorbed it is associated with a set of phenomena or a state which is the manifestation of its physiological action. According to Dr. Gill much confusion has been introduced into the study of the problem by not recognising these three factors and attributing to the physiological action of the drug results which are really due to one or other of the actions associated with it. Both the negative and physical action lead, of necessity, to a certain amount of asphyxia, and their effect will be markedly increased by anything which impedes free respiration or free circulation of the blood through the lungs. As soon as any asphyxial element is introduced into the administration it immediately becomes a most important causal factor of a set of phenomena which, though co-existing with those which result from the physiological action of the chloroform, are quite distinct from it, and should not be attributed to it. We can thus see how complex the problem is, and how much care is necessary before one attributes any phenomenon in the course of an anæsthesia to the physiological action of the drug used. In discussing the commonly received chloroform hypothesis, Dr. Gill has no difficulty in showing that this care has not been always taken, and consequently that the propositions on which this hypothesis is founded are not always reliable. Having in this manner cleared the way our author then proceeds to investigate the problem on the lines he has laid down. The state of unconsciousness induced by chloroform he divides into two degrees—"anæsthesia," *i.e.*, the lowest degree of chloroform unconsciousness, and "narcosis," or the deeper degree. The state of anæsthesia is sufficient for all the requirements of surgery, and the state of narcosis is to be avoided as tending rapidly to the region of danger. Anæsthesia is characterised by free respiration, normal colour, muscular relaxation and a contracted pupil. With a constant chloroform-air atmosphere this condition remains stable for a time, but in order to maintain this state constant the proportion of chloroform in the atmosphere must be methodically reduced, for some part or parts undergo a change of condition in the course of chloroform action in the way of opposing less resistance to its influence. The state of narcosis differs from the state of anæsthesia chiefly by a certain duskiness of the colour of the patient and by a dilated and sluggish pupil. In the former state normally the negative action of the drug produces little result and the physical action is compensated for by the increased action of the respiratory pump, but in the latter state both negative and physical actions produce important modifying results. Dr. Gill is no advocate for elaborate appliances for the administration of chloroform, but recommends the use of a twofold piece of lint turned into half a cone and so placed on the face that the apex is at the top of the nasal ridge and all communication with the external air shut off except at the base, which remains permanently open; on this lint the drug is dropped from a drop bottle.

We have said enough to indicate the nature of the solution which Dr. Gill is prepared to offer of the chloroform problem, and we believe he has done signal service in insisting on the complex nature of the problem to be solved and the necessity of taking into consideration all the factors and apportioning to each its proper place.

(*a*) "The $CHCl_3$ Problem." By Richard Gill, F.R.C.S., Chief Chloroformist to St. Bartholomew's Hospital. Vols. I. and II. 8vo., pp. lxxvi., 304, and 293. Edinburgh and London: William Blackwood and Sons. 1906.

How far his final conclusions will be accepted we are not prepared to say. He seems inclined to believe that the phenomena of chloroform anæsthesia are to be explained by the interference with tissue nutrition resulting from the deprivation of the blood of some of its oxygen by the chloroform, but it is difficult to accept this conclusion in view of his own admission that normal anæsthesia should not be accompanied by any apparent change in the colour of the blood. The book will well repay a careful study, but its length and the many repetitions which it contains will, we fear, prevent many from devoting the time to it which is necessary for mastering its contents.

SYPHILIS AND SMALL-POX. (*a*)

THE subscribers to the New Sydenham Society will have no cause to be dissatisfied with the volume presented to them by their council this year, for it contains a collection of papers which for scientific study, for practical importance, and (may we add ?) for romantic interest, would be hard to beat. For we have here the translations of all the original papers of Schaudinn and Hoffmann on the Spirochæta Pallida, and we are able to go through all the steps which enabled those investigators to make the most momentous pathological discovery of recent years. Then are given Metchnikoff's and Roux's four communications on their experimental inoculation of apes with syphilis, and the results they obtained. Then follow some studies on small-pox, which if not of quite the same sensational character, are at the same time profoundly interesting. The first of these is "The Life History of Cytoryctes Variolæ Guarnieri," by Professor Calkins, of Columbia University. This observer is convinced that he has worked out the parasitic cause of variola and vaccinia by tracing the development of the life-cycle of certain bodies observed in the lesions of those diseases by Guarnieri in 1892, and called by him Cytoryctes Vaccinæ. These bodies are regarded by Professor Calkins as sporozoa, and he gives in detail his grounds for the opinion. These conclusions are confirmed in the next paper, "Epicrisis," by Dr. W. T. Councilman, who brings additional evidence to support the view of Professor Calkins. A short paper of clinical observations on small-pox by Dr. I. R. Bancroft concludes the volume. We heartily thank the council of the Sydenham Society for this exceptionally valuable book.

THE YEAR-BOOK OF PHARMACY. (*a*)

THE small size of the present volume, which at once attracts the reader's attention, is due to the reduction in the number of pages of the Year-Book, which reduction the editor explains was necessary. But we regret to find that the parts deleted include the introduction which for forty odd years gave such an excellent summary of the progress of pharmacy and the collateral sciences during the year. The chemical abstracts are also abridged and the "Notes and Formulæ" left out. We would have preferred to see the price of the volume raised, say, to 10s. 6d., to this excision of so much valuable material. We have, however, to deal with the book as we find it, and we are free to say that in what it does contain, and it is two-thirds the size of preceding volumes, it remains unequalled as a Year-Book on the subject of Pharmacy. The selections are very happily made and the literature of Europe and America on the subject is laid under tribute. If we have a fault to find it is at the space given to the proceedings of the Congress ; by judicious deleting we think this action might be reduced one half and space found for the much more interesting preface the absence of which so many must regret.

HEBBLETHWAITE'S NOTES ON GENERAL PRACTICE. (*a*)

UNFORTUNATELY at the present time many men enter upon general practice without any real experience, save what has been picked up at odd times. Hospital training alone will not make one a good family doctor. The gold medalist of to-day may be a total failure to-morrow when confronted with a case of measles or a difficult midwifery case. To all such Dr. Hebblethwaite's little book appeals. Within its pages he gives an account of his own experiences, which after all are those of everyone of us. He starts with the consideration of what he terms "peritoneal catastrophies." In this chapter he deals with perforation cases and ruptured ectopic gestation. He emphasises the importance of sudden acute abdominal pain in such cases. The chapter of medical notes is brimful of useful hints, and contains many facts known only to the practitioner of long experience. Some are not to be found in text-books, and can only be gathered out of a vast accumulation of literature after much searching. His treatment of gastric ulcer is to be commended. It is simple and most explicit. He does not content himself with mere generalisations, but goes into detail, and states what exactly the patient is to have, when and why. Another useful paragraph is the one on the diagnosis between modified small-pox and varicella. He has also something to say on the subject of urine testing, and insists on the great importance of this in practice.

The chapter of surgical notes is also excellent, as may be said of that containing notes on infants and children. In the latter section we find directions for infant feeding which are sound and practical. The last chapter is devoted to midwifery and has but one fault: it is far too brief. In fact, this is the only defect in this interesting and instructive notebook, which book we have read with pleasure.

THE FROG. (*a*)

PROFESSOR MARSHALL'S wonderful little book on the frog is so very well known and so much appreciated that it is needless to comment on its merits. It has now reached the ninth edition, edited by Dr. Gamble, who has revised the chapter on development, and added some figures. Very fitting and amply justified is the tribute which the present editor pays to Dr. Marshall's capabilities: "The late Professor Marshall had so complete a grasp of the difficulties which confront the student of elementary zoology, and so great a sense of proportion and arrangement, that no substantial alteration can increase the educational value of his work." There are now thirty-eight illustrations, and we are glad to see that many of the fresh ones are given as plates, and being drawn on a large scale, the student is put to the minimum of trouble in differentiating the various features. The book is now provided with a most serviceable cover, which will stand an enormous amount of wear, and finally, there is a most comprehensive index. We think that everything has been done by Dr. Gamble and his coadjutors to render the book as valuable as possible, and the only direction in which we think an improvement possible is for the skeletal illustrations to be coloured so as to show the cartilage, cartilage-bones and membrane-bones, as some students are put to a considerable amount of trouble in ascertaining the nature and development of the various portions of the skeleton.

(*a*) "Selected Essays on Syphilis and Small-Pox." Translations and Reprints from various sources. Edited by Alfred E. Russell, M.D.Lond. M.R.C.P. With illustrations and charts. London : The New Sydenham Society. 1906.

(*a*) "The Year-Book of Pharmacy." Comprising Abstracts of Papers relating to Pharmacy, Materia-Medica, and Chemistry, Contributions to British and Foreign Journals from July, 1905, to July 1906, with the Transactions of the British Pharmaceutical Conference held in Birmingham, July, 1906. Editor of the Year Book, J. O. Braithwaite ; Editors of the Transactions, E. Saville Peck, M.A., and Edmund White, B.Sc., F.I.C. London: J. and A. Churchill. 1906,

(*a*) "Notes on General Practice." By S. M. Hebblethwaite, M.D. Lond., etc. London : The Scientific Press, Ltd. 3s. 6d.

(*a*) "The Frog : an Introduction to Anatomy, Histology and Embryology," by the late A. Milnes Marshall, M.D., D.Sc., M.A., F.R.S. Ninth edition. Edited by F. W. Gamble, D.Sc., Assistant Lecturer and Demonstrator in Zoology, University of Manchester. Price 5s. Pp. 172 and x. ; 38 illustrations. London : David Nutt. 1906.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT MEDICAL LITERATURE.

The Mechanical Effects of Lessened Atmospheric Pressure upon the Organism. Jacobi (*Deutsche. Med. Woch.*, 1907, No. I.), starting from the fact that all the influences of a mountain climate upon invalids and upon healthy persons cannot be explained as due to a lessened intake of oxygen, has investigated the above indicated problem. Weber had previously shown that the lessened air pressure at a height of 1,300 metres tended to increase the pliability of the muscles. By the help of some very ingenious apparatus, Jakobi now shows that of necessity important changes must similarly take place both in the lungs and in the circulation, more especially, as far as the latter is concerned, in the great veins. He shows that the increase of the red cells is the result of an impoverishment of the circulating blood of these cells, which in fact become accumulated in the dilated veins of the systemic circuit, and in the pulmonary circuit. From this it follows, as after a hæmorrhage, that a rapid new formation of red cells takes place. M.

Relation of the Thymus to the Reproductive Organs.—According to the investigations and experiments of several authors, there appears to be a certain functional relation existing between the thymus gland and the testicle. In fact, an antagonism appears to exist between the two organs in the sense that the development of the one hinders the development of the other. Soli (*Policlinico*, 1906, *Ser. Med.*, No. 12) reports the result of his investigations, made at the Institute at Modena, in connection with this matter, and formulates them as follows: (1) Under similar conditions the thymus of the capon is larger both in weight and volume than that of the cock; sometimes, indeed, it is double the weight in the former. (2) On the other hand, in young cocks, from whom the thymus gland has been removed, the testes become considerably less both in weight and size. M.

Dulness Behind the Inner Third of the Left Clavicle.—The current number of the *Archives of Pediatrics* (February, 1907, p. 92) contains a short paper by Dr. Hamill, in which he maintains that in normal children an area of dulness can almost invariably be found behind the inner third of the left clavicle. The authors' attention was first attracted to the subject by his endeavour to find evidence of enlarged bronchial glands in children with bronchopneumonia. He found in almost all cases the above-described patch of dulness, and then, on extending his observations, found it also in cases without pulmonary trouble. The area varies in extent, but usually is limited to the inner third of the clavicle, and the first intercostal space immediately below it. Dr. Hamill believes its presence to be accounted for by the posterior position of the lung in early life, which enables the great vessels to come into more intimate contact with the anterior chest-wall. M.

The Parathyroid Glandules in Paralysis Agitans.—**It has been suggested that the cause of paralysis agitans might be** found in some pathological alteration of the parathyroid glands, owing to the changes that are found in animals after removal of these structures. These changes consist, in the first place, of a fibrillary tremor, followed for some days by persistent clonic spasms in the voluntary muscles, and occasionally by symptoms of tetany. To settle the question, Thompson (*Journal of Med. Research* December, 1906) has examined the parathyroids obtained from nine cases of Parkinson's disease, and has compared the material obtained with the glands removed from forty other autopsies. As a result of this investigation, he is able to state that there is no morphologic ground for the assumption that the parathyroid glandules are insufficient in paralysis agitans. Although the glands in the nine cases were from individuals of advanced age, they did not show any alteration either macroscopic or microscopic, as compared with those obtained from individuals who had died of other diseases. M.

The Blood in Jaundice.—Morawitz and Biereh have investigated the blood in cases of icterus (*Archiv. fur Exper. Path. u. Pharm.*, Bd. 56). They point out that in the majority of icteric patients there is no tendency to the occurrence of hæmorrhages. In these cases the coagulation time of the blood is normal. When the tendency exists, the coagulability is greatly diminished, often down to one-third of the normal. This inhibition of coagulation is not attributable to the direct action of the bile salts, nor does it arise from any defect in the fibrinogen; but rather from the tardy formation of the fibrin ferment, perhaps due to some defect in the thrombo-kinase. In the severe types of the icteric hæmorrhagic diathesis, some defect of the blood vessels is also present. M.

New Researches on Treatment of Epilepsy.—Voisin and A. Rendue (*Archiv. de Neuralgie*, December, 1906) describe extensive experiences with the administration of bromides and deprivation of salt in the treatment of epilepsy. Their conclusions are to the effect that the interposition of a period of deprivation of salt and of bromide, in the midst of treatment with large doses of bromides, has a very beneficial effect in cases of "essential" epilepsy with numerous seizures. These brief periods of dechloridation rest the organism without entailing the inconveniences observed with other techniques. They also prevent too intense action of the bromides, which in time does more harm than good as the necessary nervous reaction becomes exhausted. Increasing the amount of the bromides on an ordinary diet gives the same results as are obtained with small doses of bromides on a salt free diet. They give four grammes of Pot. Brom. for ten days, then ten grammes for ten days, with the ordinary diet during these two periods, followed by ten days without either salt or bromide. These doses apply to adults, and generally also to young people from 16 to 18. The various details of their experiences are tabulated showing that this dosage was worked out as the basis of wide experience with larger and smaller doses—the former proving unnecessary, and the latter inadequate. D.

Rudimentary Eventration of the Diaphragm.—Hoffman, *Mun. Med. Woch.*, January, 1907). Eventration of the diaphragm is a condition in which, owing to weakness of the diaphragm, its position is very high on one side, usually the left, the lung is compressed, the heart displaced and tympany due to the stomach or intestines may extend up to the second rib. Hoffman has observed a number of cases in which this condition was present in a rudimentary form, and believes that it is not infrequent. The diagnosis is best made by means of the X-Rays, which shows the high position of the diaphragm, and just beneath it a rounded, bright area due to air in the stomach. The symptoms occur chiefly after meals, and consist of pain in the region of the stomach and palpitation. The treatment includes small frequent meals, and breathing exercises to strengthen the diaphragm. D.

Functions of the Pancreas and Influence of the Character of the Food.—Wohlgemuth (*Berlin, Klin Woch.*, 1907) reports the findings in the case of a young man left with a fistula into the pancreas after rupture of the organ in a bicycle accident. Experiments with various kinds of food to determine which kind induced the least secretion of pancreatic juice, and this had a tendency to promote the healing of the wound, showed that the production of the pancreatic juice could be readily controlled by care in selection of articles of food. Fats and albumin checked the production of the pancreatic juice, while the carbohydrates induced a copious secretion. The secretion could be further reduced in amount by frequent administration of moderate doses of sodium bicarbonate, especially during the meals. It was also found possible to substitute the loss of pancreatic juice through the fistula by administration of a pancreas preparation by the mouth several times a day. When the patient ate fat in the form of cream and milk the pancreatic juice ceased to flow from the fistula. After eating meat, it flowed again, but on a carbohydrate diet an actual stream poured out of the fistula. D.

The Reflexes During Sleep.—R. Kutner (*Deut. Med. Woch.*, January, 1907). It has been claimed that the tendon reflexes are decreased and often absent during sleep. Kutner found this was not the case. In a large proportion, however, of cases of general paresis and of delirium tremens he found a positive Babenski only during sleep. This he attributed to a slight lesion of the pyramidal tracts, not sufficient to cause a positive Babinski when the patient was awake. D.

Myxœdema Following Bullet Wound of the Neck.—Gottell (*Journ. R.A.M.C.*, March, 1907) describes the case of a man who was wounded by a bullet during the South African war, and who on recovery developed well marked symptoms of myxœdema. It does not appear that the bullet wounded the thyroid gland itself or damaged its blood supply, but there is evidence that it damaged the left inferior and probably the middle cervical ganglion, and many of the nervous connections of the left lobe of the gland. The symptoms of myxœdema appeared some six months after the injury and persisted for nearly six years, and then disappeared after a three months treatment by thyroid extract. K.

Use of X-Rays in Unresolved Pneumonia.—Esdall and Pemberton (*Amer. Journ. Med. Sciences*, February, 1907) record their experience of this form of treatment of unresolved pneumonia. Previous investigations of the effect of X-Rays had suggested the probability that their action was really due to some stimulant effect on the ferment processes normally resident in the tissues. It is now generally admitted that the resolution of the exudate in ordinary pneumonia is the result of some fermentation processes, and according to Flexner lack of resolution is often due to insufficiency or absence of this ferment. The authors point out the importance when estimating the value of this treatment to exclude those cases which are due to a persistance of the inflammation, or those in which resolution has been so long delayed as to permit of organisation of the exudate. In all five cases were submitted to the treatment, ten days or a fortnight at least having in each case been allowed to elapse after the disappearance of the fever and signs of toxæmia with the persistence of the signs of consolidation in the lung before the treatment was commenced. In the first case the affected area was exposed to the rays for five minutes on four consecutive days, and a week later the man left the hospital with practically no abnormality to be detected in the chest. The second patient was exposed daily for seven days, and three days after the completion of the treatment the merest trace of dulness was to be detected over what had been previously a completely consolidated lobe of the lung. In the other cases equally satisfactory results were obtained. In two cases elaborate metabolism experiments were carried out. In one of these cases after the first exposure to the rays, "the nitrogen increased to more than double what it had been before, and the chlorides showed an almost equally striking increase; the phosphates were somewhat less decidedly increased, while the uric acid showed relatively little change. The increase persisted in less marked degree, gradually decreasing coincidently with the decrease of the solidification, and when the latter had disappeared, excretion had reached about its former level." The other case in which metabolism experiments were made showed similar results. These effects on metabolism are very similar to those noted by these authors in a case of leukemia treated in this manner, in which there was extremely rapid improvement in the general condition, in the splenic tumour and in the leukocytosis. K.

A Case of Loss of Memory.—Burr (*Amer. Journ. of Insanity*, January, 1907) records an interesting case of loss of memory in a man of about sixty years of age. Some six years ago the man was found wandering about the streets confused and unable to give any account of himself. He knew his name and occupation, but did not know where he lived. He was sent to hospital, where for the first few days he was quiet and well behaved, and then suddenly became so violent that it was necessary to transfer him to the asylum. In a few days the attack of violence ceased and he passed into the condition in which he has remained ever since. At present he appears to be in perfect physical health, but has complete loss of memory of many years of his life, and an absolute inability to remember anything happening at the present time for even a few minutes. There is little evidence besides this of any mental disease, there being no disturbance of the moral sense and his conduct being irreproachable, and there is no failure in his knowledge of his personality. He appears to be able to reason correctly, and never starts from any false (insane) premise, nor has he any delusions or hallucinations. He reads aloud fairly well and understands what he reads, but forgets the beginning of a paragraph before he gets to the last sentence. K.

Medical News in Brief.

The Medical Golf Tournament.

We are asked to announce that this event will take place on Thursday, May 30th, and that application has been made to the Burnham Beeches Golf Club for permission to play off the event on their links. To secure the continuity from year to year of this popular fixture and to promote the interests of golf among practitioners, there has been founded a Medical Golfing Society with an annual subscription of 4s., the payment of this sum including entrance to the tournament. Any person on the medical or dental registers can join by sending 4s. to the Honorary Treasurer, Medical Golfing Society, 1, New Cavendish Mansions, New Cavendish Street, London, W.

Alleged Assault by an Asylum Nurse.

Bertha Ollier, of Lawton, Staffordshire, was summoned at Lancaster for assaulting Agnes Cooper, a patient in the County Asylum. For the prosecution, which was at the instance of the Director of Prosecutions, it was stated that whilst attempting to brush the hair of Cooper defendant was assaulted, and in a subsequent struggle lost her temper and struck the patient twice with a slipper. Bridget Dowsey, who until recently was a nurse at the asylum, said defendant struck the patient with a felt slipper, but only in order to release herself from the woman's grasp. Cooper was a violent patient, and this was not the first time she had attacked a nurse. Dr. Cassidy medical superintendent, stated that the defendant admitted to him that she had done wrong, and expressed her sorrow. He complimented her on telling the truth, and dismissed her on the spot. The reason the Asylum Court had not prosecuted in this case was because he advised them not to, deeming that summary dismissal was a sufficient punishment. Mr. J. C. Jackson, for the defence, submitted that he had no case to answer, and the Bench, after a short retirement, dismissed the case.

Ptomaine Poisoning.

On March 13th a case of fatal ptomaine poisoning as the result of eating tinned salmon came before the Manchester City Coroner. The victim was a four-year-old girl named Hilda Jackson, of Embden Street, Hulme. On Saturday week five members of the family and a friend had some salmon which had been purchased the same day. Four of them became unwell and the girl Hilda, after a week's illness, died on Saturday. The shopkeeper told the coroner that the salmon had been in stock three months, which was not considered a long time. Tinned goods could be kept in stock for years and still be all right. "Death from ptomaine poisoning," was the verdict.

Spotted Fever.

At the meeting of the Brampton District Council on March 13th, Dr. Symington reported that a girl had died from cerebro-spinal meningitis at Little Corby, midway between Brampton and Carlisle. The girl had come home ill from Whitehaven, where she had attended to a boy who had been unwell, and had since gone to school at Wallsend. After the departure of this boy for Wallsend she had occupied the bed in which the boy had slept at Whitehaven. No case of spotted fever had, however, been notified at Whitehaven. The Brampton Council decided to hold a special meeting to make spotted fever notifiable.

Asylum Doctor Threatened.

A German, named George Beck, living at Upton Park, was charged at Stratford on March 8th, with feloniously causing Dr. David Hunter to receive a letter threatening to murder him. Mr. G. E. Hilleary who prosecuted, said that towards the end of August of last year the prisoner's wife was admitted to the Goodmayes Asylum, and shortly afterwards the prisoner went there and demanded her release. He made serious allegations as to the ill-treatment of the patients, and said that horrible cruelties were practised at the asylum. Subsequently he sent letters to the infirmary in which, referring to the medical superintendent, he said, "Dr. Hunter . . . If he is not careful he will be in his wooden box soon. I am after his body." Prisoner, who contended that his wife was quite sane, was remanded.

Dublin Hospital Sunday Fund—Annual Meeting.

The annual meeting of the supporters of the Dublin Hospital Sunday Fund was held last week in the Molesworth Hall, Sir Robert Jackson presiding.

Mr. William Perrin, Hon. Secretary, submitted the report, which stated :—" The collections were made on November 11th, 1906, in 272 places of worship. Ten congregations, which in 1905 had collections, producing the sum of £28 5s. 3d., did not join in 1906. On the other hand, collections, amounting to £26 3s. 5d., were made in eight places of worship which had not any collections in 1905. The amount contributed to the Fund for 1906 was £3,767 11s. 3d. (which includes a generous donation of £100 from R.P.), being an increase of £2 9s. 4d. as compared with 1905. The Council observe that while there was a reduction in the amount collected in 126 places of worship, there was an increase in 136. In ten cases the amounts were the same as in 1905. The expenses for the year amounted to £234 0s. 10d., being £3 15s. 4d. less than in the preceding year, or 6.21 per cent. on the total sum collected. The total amount to the credit of the Fund for the year 1906 was £3,887 1s. 6d., including a balance from the previous year of £104 15s. 8d., and £14 14s. 7d., interest allowed by the Royal Bank.

Annual Meeting of the British Medical Association.

The local arrangements for the visit of the British Medical Association to Exeter in the summer are making satisfactory progress. The South Western Branch of the Association, by whom the invitation to hold the annual Congress at Exeter was given, have raised a guarantee fund, and the members of the profession are sparing no efforts to make the gathering a success. It is thirteen years since the Association visited the West of England, and its members have not foregathered at Exeter since 1842, ten years after the foundation of the Association. On that occasion Mr. J. H. James, the principal surgeon on the honorary staff of the Devon and Exeter Hospital, was president. In 1864 the annual meeting was held at Torquay, and Plymouth was the place of meeting in 1871. The 1894 assembly was held at Bristol, where the Association was started in 1833.

Malta Fever.

A further report of the commission appointed by the Admiralty, the War Office, and the Civil Government of Malta for the investigation of Malta or Mediterranean fever has lately appeared. In this Staff-Surgeon E. A. Shaw details experiments relating to various possible paths of infection by the micro-organism of the disease. Major W. H. Horrocks supplies a valuable contribution on outbreaks of the fever in Gibraltar and the general question of infection by goats. The opinion is expressed that the rapid disappearance of Mediterranean fever from the Rock, which commenced in 1885, was intimately associated with the greatly-lessened importation of goats from Malta. At the present time the goat-keepers introduce Spanish goats, but, in the interests of the public health, it is held that, notwithstanding the healthy conditions now prevailing, all goats brought to Gibraltar should be quarantined until examinations of the blood have shown them to be free from infection. Dr. J. W. H. Eyre describes experiments made by him with the object of obtaining a bacteriological serum suitable for therapeutic purposes in cases of Malta fever. The results were not, however, of a character to warrant belief that an "anti-serum" had been secured possessing the requisite properties. A useful bibliography of works and papers on Malta fever proceeds from the same writer.

Trinity College, Dublin.

During Hilary Term, 1907, the following candidates passed :—

Intermediate Medical Examination (Part I.).—Robert E. T. Tatlow, Victor B. Kyle, Hugh S. Metcalfe, William P. H. Smiley, Charles D. Hanan, Charles B. Jones, Desmond Drew, James D. Murphy, Alexander K. Cosgrave.

Final Medical Examination (Part II. Surgery).—Frank R. Seymour, John Gray, Ernest Jameson Edward C. Stoney, George G. Vickery, Francis W. H. Bigley, Henry P. Hart, Albert T. J. M'Creery, Arthur E. Knapp, Rev. Richard B. Bryan, John W. Lane, George H. Stack, John H. Morton.

Diploma in Public Health. (Part I.).—Cecil Scaife.

Previous Dental Examination (Anatomy and Institutes of Medicine).—Arthur A. Campbell ; Chemistry and Physics, George Elliott.

A telegram from Tangier dated Saturday last, mentions that Dr. Manchamp, a resident physician at Marrakesh, has been brutally murdered by natives. He had hoisted a white flag over his house in order to distinguish it, and the Moors, thinking it indicated an intention to install wireless telegraphy, went to the house in a body and stoned him to death, stabbing the body afterwards in their frenzied rage. The French Government is reported to be taking energetic action in the matter with the object of punishing the ring-leaders of the outrage and obtaining substanitial damages for those dependent on our ill-fated *confrere.*

NOTICES TO CORRESPONDENTS, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Original Articles or Letters intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

Contributors are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions, the same rule applies as to office; these should be addressed to the Publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s. Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

D.M.R.—It does not follow that because a patient is of good mental power that the cerebellum is not affected. In adults the mind is not affected in cerebellar disease, as a rule, though in children defective cerebellar development is a common cause or accompaniment of idiocy.

Jahr.—An anti-gonococcic serum has been prepared in America, where it has been employed by Dr. J. Rogers. He reports very good results from its use in small quantities. Twenty to sixty minims are injected subcutaneously every day or every other day in gonorrhœal rheumatism, and in early cases the acute symptoms are said to have subsided in a week or ten days. We do not know of any available serum manufactured in this country.

Coccus.—Sabourand's seborrhœa bacillus may be demonstrated by squeezing out the contents of a sebaceous follicle, squeezing them between two slides, dissolving the fat in ether and staining with methylene blue.

A Yorkshire Subscriber.—Your surprise is well founded; the strange part of it is that no one thought of writing on the subject in the same attractive way previously. We understand the success of the book is almost phenomenal.

THE FLOWING TIDE OF CHARITY.

According to the annual report of the Charity Commissioners, upwards of one thousand new recognised charities have been established in England and Wales during the past four years, with a cash value of £2,640,387 and producing a yearly income of £84,568. The total number of charities now under the control of the Commissioners is 26,497, with an aggregate value of £25,472,703. Of the objects to which the new charities are applicable, what may be called medical charities predominate, while a considerable proportion of the miscellaneous charities are applicable for nurses, nursing homes, dispensaries, and the like.

Mr. S. (Thomas's).—We quite agree with you that there is room for a book giving the student in a plain and practical way the fundamental principles upon which medical language is built, because many have had no real early training in Latin.

Dr. G. (Skye).—According to Conrath, the ileocæcal region is the seat of election of intestinal tuberculosis, and is affected in 85 per cent. of all cases.

M.D. (Ilford).—"Nature healers" are also included under the law in Germany. Dr. G. Siefart, Hardenbergstrasse 39 Charlottenburg is the editor of the anti-quack journal, "Gesellschaft zur Bekämpfug das Kurpfuschertums."

L. L.—We are much obliged for your kind compliments. The gradual establishment of correct scientific feeling on that subject and cognate ones is what we endeavour to promote, and evidence such as you supply that it is appreciated is very welcome.

First Edition.—Can any of your readers tell me where I can get a book by Robert Knox (1724), entitled "Great Artists and Great Anatomists," also a copy of "An Historical Sketch of the Edinburgh Anatomical School," by Prof. Struthers.

Meetings of the Societies, Lectures, &c.

Wednesday, April 27th.

Hunterian Society (Poplar Hospital Blackwall, E.).—4 p.m.; Clinical Meeting. Cases can be seen at 3.30 p.m.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. J. Cantlie: Clinique. (Surgical.)

North-East London Post-Graduate College (Tottenham Hospital, N.).—Cliniques:—2.30 p.m.: Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Out-patient (Dr. Whipham).

Central London Throat and Ear Hospital (Gray's Inn Road, W.C.).—5 p.m.; Demonstration: Dr. A. Wylie: Pharanx.

Thursday, April 28th.

North-East London Post-Graduate College (Tottenham Hospital, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques: Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson). 3 p.m.: Medical In-patient (Dr. Chappel).

Friday, April 29th.

North-East London Post-Graduate College (Tottenham Hospital, N.).—9.30 a.m.: Clinique. Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. Leslie).

Vacancies.

Royal Devon and Exeter Hospital, Exeter. House Surgeon. Salary £120 per annum, with board, apartments, and washing. Applications to Samuel S. Cole, Acting Secretary.

Leicestershire and Rutland Asylum.—Second Assistant Medical Officer. Salary £130 per annum, with apartments, board, and washing. Applications to W. J. Freer, Esq., New Street, Leicester.

University of Birmingham.—Demonstratorship in Anatomy. Salary £150 per annum. Applications to Geo. H. Morley, Secretary.

Wolverhampton and Staffordshire General Hospital.—Senior House Surgeon. Salary £100 per annum, with board, lodging and laundry. Applications to J. Stephen Neil, House Governor and Secretary, Wolverhampton.

Cornwall County Asylum. Bodmin.—Third Assistant Medical Officer.—Salary £140 a year, with furnished rooms, rations, laundry, and attendance. Applications to Medical Superintendent.

Staffordshire County Asylum, Cheddleton, Leek.—Junior Assistant Medical Officer. Salary 150 per annum, with board, furnished quarters, and washing. Applications to the Medical Superintendant.

Leeds Public Dispensary.—Two Junior Resident Medical Officers. Salary £100 per annum, with board and lodging. Applications to the Secretary of the Faculty, Public Dispensary, Leeds.

The General Infirmary at Leeds.—Resident Casualty Officer. Salary £125 per annum, with board, lodging, and washing. Applications to the Secretary to the Faculty, General Infirmary, Leeds.

Monaghan District Lunatic Asylum.—Second Assistant Medical Officer Salary £100 per annum, with furnished apartments, etc. Applications to R. L. Donaldson, Resident Medical Officer (See advt.)

Appointments.

Bergin, Frank Gower, L.R.C.P., M.R.C.S., House Surgeon at the Bristol General Hospital.

Blacket, James Francis, M.B., B.S.Lond., Assistant House Physician at the Bristol General Hospital.

Briscoe, William Thomas, M.D., M.Ch.Dublin, Medical Officer for the Pewsey District by the Chippenham (Wilts) Board of Guardians.

Carey-Evans, T. J., M.D. Brux, M.R.C.S., L.R.C.P.Lond, House Surgeon at the Royal Southern Hospital, Liverpool.

Coulson Thomas Edmund, M.B., Ch.B.Edin., Senior House Surgeon at the Bristol General Infirmary.

Elliott, William Harold Arthur, M.B., B.S.Lond., L.S.A., Medical Officer to the Bristol Dispensary.

Hughes, Edward Blythe Hurst, L.R.C.P. and S.Edin., L.F.P.S. Resident Medical Officer at the Newport (Mon.) Workhouse.

Miller, A. H., M.B., B.C.Cantab., Resident Medical Officer to Outpatients at Queen Charlotte's Hospital.

Pinniger, Wilfrid J. H., M.B., B.S.Lond., L.R.C.P., M.R.C.S., Casualty House Surgeon to the Bristol General Hospital.

Taylor, J. Francis, M.R.C.S., D.P.H., Medical Officer at Leyton.

Thompson, Theodore, M.D.Cantab., M.R.C.P.Lond., F.R.C.S.Eng., Assistant Physician at the London Hospital.

Wade, Reginald, M.R.C.S., L.S.A., Medical Officer of Health for the Highbridge (Somerset) Urban District.

Marriage.

Waugh—Young.—On March 20th, at Sarratt, Hertfordshire, John Waugh, M.D., J.P., of Conger House, Toddington, Beds., to Alice, second daughter of the late Geo. Young, Esq.

Deaths.

Casley.—On March 23rd, at Elmroyd, Park Road, Ipswich, in his 56th year, Reginald Kennedy Casley, M.D., C.M. (Edin.)

Leach.—On March 11th on the S.Y. Argonaut, John Comyns Leach, M.D., J.P., of the Lindens, Sturminster Newton, Dorset, aged 65.

O'Connor.—On March 15th, at 40 Grove End Road, St. John's Wood, London, Ignatius Jeremiah O'Connor, third son of the late William O'Connor, M.D., aged 59.

Smith.—On March 22nd, at Kent House Nursing Home, Torquay, Clement Madely Smith, M.D., of St. Enoder, Cornwall, and Argyll Hall, Torquay, late of 1st Punjaub Cavalry, in his 80th year.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIV. WEDNESDAY, APRIL 3, 1907. No. 14

NOTES AND COMMENTS.

The Reprieve of Rayner.

IN our last issue we published a letter from a correspondent on the desirability of commuting the death sentence in the case of Horace George Rayner, and we believe, though that letter was strongly worded, that in the main it represents the general feeling of the medical profession with regard to the case. The heredity of the unhappy Rayner was about as bad as it could be, and his environmental conditions since the earliest days were no better. He was born and brought up under anti-social conditions, and it is proposed to punish him for an anti-social act, committed in the depths of despair and probably in a moment of temporary insanity. The evidence of the medical witnesses at the trial, to the effect that at the time of his examination by them there was no insanity present, was doubtless correct, but it is equally certain that had he killed himself as he intended, the coroner's jury would have found him "temporarily insane." Rayner, the illegitimate outcast, and Thaw, the pampered millionaire, differ at least in this, that the former's act probably was not deliberately intentional, and certainly was utterly irrational as a method of clearing himself, while Thaw's was an act of premeditated vengeance against a man who had wounded his pride. It is difficult to see what useful social purpose the execution of Rayner would have accomplished; while the commutation of his sentence at least points to a discrimination on the part of society between the victim of circumstance, who has never had a chance, and the victim of sensualism who has thrown his chances away. The pardon granted in his case is not only the humane but the scientific course to follow.

Death Investigation.

AN influential deputation, composed of members of the London County Council and of the Medico-Legal Society, waited on the Lord Chancellor recently to point out some anomalies of the coroner's position, and of the faulty system under which deaths are registered. Sir William Collins, who has been chairman of both bodies, introduced the deputation, and with them laid before the Lord Chancellor the points in connection with death-recording and burial which medical men know well to stand in need of reform. For instance, it is preposterous that the preparation of a case for submission to a coroner's court should be in the hands of an officer who is not only uneducated, but too often venal as well; what evidence shall be sought if that laid before the Court is entirely in the hands of the coroner's officer? Then, too, money is notoriously wasted in the holding of unnecessary inquests, simply because there is so little elasticity in the law as relating to coroners. The cause of many a death could be cleared up quite satisfactorily by a medical man whose business it was to make the necessary inquiries and satisfy himself that the death was natural. And then, of course, no dead body should be buried without a certificate, even in the case of still-born children. The number of still-born murders is probably higher than is dreamed of by even well-informed people.

The Lord Chancellor and Caution.

THE Lord Chancellor gave a hearty welcome to the deputation and said he considered the matter one of real and great importance, adding that without loss of time he would personally look into the matter and take counsel as to what steps could be adopted to alter such a state of affairs as was laid before him. The decision of the Lord Chancellor is very good so far as it goes, and we hope that his characteristic energy will carry him through his task without loss of time; but at the same time we hope that in arriving at his decision he will be preserved from falling into a pitfall by the way into which, if unwary, he may be led. When we say that Mr. Troutbeck formed one of the deputation and gave forth his own views, the danger we allude to is very obvious to all medical men. Mr. Troutbeck urged the need of skilled medical advisers to supervise death registers, to make the preliminary enquiries in uncertified deaths, and to perform the necessary post-mortems. Now such an officer attached to a coroner's court would be a valuable one doubtless, provided that his duties were properly defined. It has been shown over and over again that to judge merely from a post-mortem examination as to the cause of death is to leave the whole of the most important evidence out of account, namely, the clinical history and appearances. These can only be supplied by the medical practitioner in attendance, and if any attempt is made to oust him in favour of a bureaucratic officer it will prove a fatal mistake. There is room for both family practitioner and medical investigator in their defined spheres for, in spite of the ignorant sneers of certain superior people, the medico-legal skill a busy general practitioner acquires in a lifetime is often of more practical service than the generalisations of many text-books.

Failure to Notify.

We have had occasion two or three times lately to call attention to the overbearing and stupid way in which many local authorities treat medical practitioners in their districts. In illustration of this principle we may cite a case tried in the Otley Police Court the other day, when Dr. Henry White, of Bradford, was summoned for failing to notify a case of diphtheria that he had attended in the neighbourhood. The facts, briefly stated, were that Dr. White was attending a child, and the Sanitary Authority got to know something of the nature of the case and suspected diphtheria. The clerk was instructed to write to Dr. White, and not getting an answer, another letter was sent later. To this an answer was received, Dr. White saying that he found the case was one of diphtheria after all, but that the girl was then convalescent, and he regretted not having reported it sooner. On this trumpery ground the local authority proceeded to summon Dr. White in the police court, and in spite of his defence that he had not notified the case because he was in doubt for a long time about the diagnosis, a fine of forty shillings and costs was inflicted. The chairman of the magistrates said "they were bound to support the local authority," and that presumably was the reason for giving such an unjust decision.

"In My Opinion."

Now it would be well if the local sanitary authorities would learn that they cannot have their cake and eat it too. A medical man has to certify that in his opinion a patient is suffering from diphtheria, scarlet fever, or whatever the disease may be. Till his opinion is formed, therefore, if he keeps to the strict letter of the law, he cannot certify, and every medical man knows that his opinion never is properly formed about many and many a case that passes through his hands. On the other hand, if the local authorities want the interpretation of the words varied, so as to cover all doubtful cases, as to which his mind is not made up, no medical man would object; but the number of notification fees would increase enormously and the consequent work thrown on the sanitary staff would be immense. It is only possible for the Act to work well by local authorities giving confidence to the medical practitioners, and leaving them to notify cases in which they are reasonably sure. Any other way, chaos lies.

Epidemic of Diphtheria in Lincolnshire.

Owing to an outbreak of diphtheria at Spalding, the medical officer of health has ordered the closing of the Spalding Central Schools. An emergency meeting of the managers was held on Saturday, and the closing of the schools was agreed to. The cause of the outbreak is unknown, but the sanitary arrangements of the school are in good order, and it is suggested that the disease had been introduced from outside. Up to the present there have been fifteen cases. Scarlet fever is also prevalent in the town, but the action of the medical officer in closing the schools was due to the diphtheria cases.

LEADING ARTICLE.

LONDON AND ITS MILK SUPPLY.

The scientific investigations of the Royal Commission on Tuberculosis, as all the world knows, have emphasised the absolute necessity of a rigorous control of the national milk supply. It seems probable in the light of the evidence thereby obtained that the major part of the terrible sum total of infantile tuberculosis and possibly a fair proportion of the disease in adults, arises from milk infection. The inevitable outcome of these clear-cut and incontrovertible propositions is that the State, whose duty it is to safeguard the public health, must enforce stringent sanitary control of farms, dairies, cows and byres, in short, of every detail concerned with the production and distribution of dairy produce. Clearly it is a feeble policy to attempt to cure consumptives by establishing palatial sanatoria such as those at Winsley and elsewhere, while we permit the careless or ignorant farmer to go on infecting the community with his tuberculous cows, and the dairymen to distribute tubercle bacilli systematically in his milk cans. Nor is the whole of the danger comprised in the spread of tuberculosis. There is no need to remind medical readers of the many epidemics of enteric fever, scarlet fever, diphtheria, foot and mouth disease, and other infections that have been traced to the agency of the ubiquitous and noisy milkman. It seems more than probable that he has a hand in the dissemination of that most fatal of infantile scourges, summer diarrhœa, just as he is probably implicated in epidemic disquamating dermatitis, otherwise known as "Savill's" disease. Under these circumstances all who have at heart the progress of the public health were rejoiced at the prompt and thorough nature of the control of the milk supply asked for in the General Powers Bill of the London County Council to be brought before Parliament this Session. Amongst other powers it petitioned for the following:—"To enable the Council to prohibit the sale of milk from any dairy situated within or without the county where the medical officer suspects that cases of infectious disease within the county occurring in more than one sanitary district are attributable to the milk supplied from such dairy. (Clause 32). To enable the Council to take samples of milk at railway stations and elsewhere in the county with a view to prevent the sale of milk unfit for human consumption. (Clause 33). To enable the Council's medical officer to require dairymen to furnish lists of sources of supply of milk and of their customers, with a view to prevent the spread of infectious disease. (Clause 34). To require dairymen to notify under penalty all cases of infectious disease among their servants, &c., and to prohibit any person suffering from an infectious disease from milking any animal whose milk is intended for consumption within the county. (Clauses 35 and 36). To enable sanitary authorities, with a view to prevent the spread of infectious disease, to require proprietors of dairies to furnish lists of their customers. (Clause 37)." The Bill itself stands for second reading on April 11th. It is somewhat alarming, therefore, to learn that the Parliamentary Committee of the London County Council report unfavourably to the foregoing proposals on the ground that they are highly controversial, and are opposed by a number of local authorities and other petitioners. This retrograde step in the face of a grave public health danger is the more to be regretted inasmuch as the entire change of political complexion in the recent election suggests that in this case the health of Londoners is not so much a matter of imperative and overwhelming importance as the trade and other private interests represented by various metropolitan local authorities. It is a thousand pities that matters of this importance should be imported into the domain of politics. The tubercle bacilli of the milkman's can infect conservatives and liberals alike, and the exclusion of so terrible and insidious a danger from our households should be the aim not alone of progressives or of moderates, but of the whole Council, grim, enthusiastic, and determined. The fight of the sanitarian has always been beset with difficulties. At every fresh advance he finds himself faced by vested interests prepared to defend their pockets at the cost of the health, or, if need be, the very lives of the community. We doubt whether in the history of the long struggle for the public health could be found a more typical instance of the contemptuous levity with which public bodies habitually treat measures advancing the public health when the latter threaten to clash with sordid petty interests. It is to be hoped, however, that the new London County Council will be warned in time, and will settle down into a wiser mood when the first flush of its exuberant success has somewhat passed away. At the same time, that august body may be reminded that in this particular matter it is acting as the pioneer, or the reverse, of an important movement affecting the policy and the lives of citizens throughout the length and breadth of the United Kingdom.

CURRENT TOPICS.

The Death of a Great German Surgeon.

News has come from Berlin of the death of Professor Ernst von Bergmann, the famous German surgeon. A few months ago we announced the public celebration of his seventieth birthday, and his visit to the Sultan of Turkey was quite of recent date. Von Bergmann was a Russian subject in Livonia, although of Teuton blood and education. He served on the Prussian medical staff in the wars of 1866 and of 1870-71, and afterwards as consulting surgeon on the Russian Danube force in the campaign of 1877. He was appointed Professor of Surgery in Berlin in 1882. He came into prominent European notice as surgeon to the late Emperor Frederick, upon whose illness he was the first to give a decided opinion as to its cancerous nature. He was generally understood to have inspired the attacks on Sir Morrell Mackenzie circulated in Germany after the Emperor's death. He also performed a slight operation some time ago upon the present Emperor. Of huge stature and blunt speech, he was one of the most familiar as well as the most popular figures in Berlin. His fame is founded on a sure basis as a scientific surgeon, apart from mere technical skill. For some five years past he has suffered from intermittent intestinal symptoms, which he himself recently diagnosed as malignant. A few weeks ago he was undergoing a cure for lumbago at Wiesbaden, when his old symptoms returned, and two operations were performed. On Monday, March 25th, however, the great surgeon died of shock and exhaustion.

"Carelessness" of a Royal Commission.

The coming extermination of tuberculous cattle has naturally fluttered the dovecotes of the farming and the dairy interest to a considerable extent. That fact was abundantly illustrated last week at a meeting of the Central and Associated Chambers of Agriculture held in London under the presidency of Lord Desborough. One of the speakers, Mr. H. Rider Haggard, maintained that it would be unfair to ask the farmers and dairymen to protect the public health by the huge sacrifice that would be involved in the systematic destruction of tuberculous cows. With regard to that attitude it may safely be assumed that no British Government would attempt to enforce such a measure except on the basis of compensation. Another speaker, Professor F. J. Lloyd, declared his belief in Koch's theory that tuberculosis in man and in the lower animals is not identical. He is reported to have said, further, that he was not proud of the scientific men of England because of the "carelessness" with which the Royal Commission's conclusions had been arrived at. We do not happen to know the precise faculty in which Mr. F. J. Lloyd fills the professional chair. Whatever its nature, however, he must surely know that to stigmatise the work of a Royal Commission as "careless" in a mixed public assembly where there is no chance either of maintaining or of refuting the charge, is to take upon himself a most serious responsibility. Fortunately "professors" who entertain doubts are, as a rule, more cautious in publishing their views and more precise in furnishing at the same time an adequate statement of their grounds of difference.

An International Standard Pharmacopœia.

The principle of *Tot homines tot sententiæ* applies to nations as well as to individuals. In habits, fashions, laws, religion and a thousand other ways one nation is sharply marked off from its fellows. Modern civilisation has done a great deal towards the development of a certain broad international cosmopolitanism. If there be need for a common understanding among the people, of the earth for one thing above all others it is for the acceptance of a common pharmacopœia with a standard method of estimation and universal drug formulæ. With a perfectly authorised Volapuk of the kind suggested, a traveller armed with his pet physician's prescription would feel safe whether it were compounded in the bazaars of Constantinople, of Calcutta, the Broadway of New York, St. Petersburg, or anywhere else in the civilised globe. For once in a way the Foreign Office has adopted a most sensible and advanced position in dealing with a socio-scientific matter. It has signed a convention, so we understand, together with the United States of America and the principal European countries, under the title of "A Treaty for the Unification of the Pharmacopœial Formulæ of Potent Drugs." The partial standardisation thus foreshadowed appears to be a step in the right direction, that is to say, towards the goal of an international pharmacopœia. By the way, is there any such technical vocabulary in Volapuk?

Poison in a Beer Bottle.

It would be interesting to find out, were such a thing possible, the number of persons who have died, say, within the last decade, from drinking poison retailed in beer bottles. Elsewhere in our columns will be found the facts of a case in which carbolic acid was sent out by the chemist in a pint black bottle bearing the label of a well-known firm of brewers. A baby of two and a half years took the bottle from the table and drank from it, causing death. A widow, who sold the carbolic, and was prosecuted under the 17th Section of the Pharmaceutical Act for selling a scheduled poison in a bottle not labelled with her name and address as seller. Defendant stated that she had carried on the business since the death of her husband, and had served the disinfectant on a statement that a child of the purchaser was suffering from fever. There was a narrow red label with the word "poison" on the bottle. As the magistrate, Mr. Cluer, pointed out, no matter how the bottle had been labelled, it would not have prevented a child of two and a half years from drinking from it. We cannot agree, however, with the further remark attributed to the learned magistrate that "it was no act of carelessness on her part which had contributed to the death." We should be inclined to say that to dispense carbolic acid in a beer bottle and without a proper label is a reckless proceeding deserving a heavy penalty. The accidental deaths from carbolic acid form a terrible death-roll every year, and in many cases the safeguards entailed by the law are grossly violated by the vendors.

Seasickness and Christian Science.

Of all the evils that have cursed mankind since the far-off prehistoric time when first they began to go down to the sea in ships that of seasickness is one of the most tragic, dramatic, and inevitable. Thousands of our fellow mortals have wrung their brains in the vain endeavour to circumvent this evil, but neither prevention nor cure has yet been attained. Icebags down the spine, drugs and patent medicines by the score, patent ships, patent cabins, patent berths, all are worthless in the face of a "choppy" sea and a rolling ship. The latest invention for steadying ships is the Gyroscope, which may, or may not, succeed where other devices have failed. It has occurred to us that in this unspeakably terrible malady of seasickness Christian Science might have a fine field for experiment. Let us take, say, two or three score miserable sufferers and put them in the hands of Christian Science healers, and make a minute and careful record of results. If faith healing be competent to perform half the wonders claimed for it by the Scientists, they will make short shrift of so slight a thing as a mere attack of *mal de mer*.

The Lord Lister Celebration.

The celebration of Lord Lister's eightieth birthday on April 4th will be of a somewhat novel character. Instead of the stereotyped dinners and presentations, it is proposed to form an International Committee for the publication of our distinguished countryman's scientific papers, prefaced by a short biography. Always a sparse writer, his contributions are scattered in many journals, and their collection will present an interesting survey of the development of one of the most momentous discoveries that has ever been made in the domain of medicine. One point that will be emphasised is the variety and originality of Lister's early researches in physiology, more especially perhaps in the direction of the coagulation of the blood, of non-absorbent ligatures and of the action of anæsthetics, the present scheme has been hailed with acclamation throughout the civilised world. Professor Elie Metchnikoff and Professor Championniere, who sat at the feet of Lister in the first days of the new discovery as representatives of the Pasteur Institute and of France, are on the list, together with Professor Ehrlich, the late Professor Von Bergmann, Professor Philip Welch, of the John Hopkins University, Professor Tilanus, of Amsterdam, Dr. Koch, Dr. Roux, Dr. Gaffky, Professor Fleuger, Dr. Franckl, Professor Poltauf, Professor Loeffler, Dr. Kossel, and Dr. Salamon, besides representatives from every British Colony, and a very large number of medical, surgical and bacteriological authorities in America. The Committee is now several hundreds strong. A meeting will be held shortly after Easter, and the form of the work, which will be published in two quarto volumes, will be decided on, and its editor and biographers officially chosen.

The Approaching Conquest of Seasickness.

"The long night of waiting is drawing to a close, and already over the hills appear the shafts of light which announce to the weary sufferer that dawn is at hand. Since the time that order came out of chaos the world has sat patiently waiting for a sign that it should master the deadly seasickness which holds it by the throat, chaining commerce with fetters of iron and hampering the interchange of friendly relations with nations over the sea. But the malady can no longer face the determined onslaught of science, and now we know how it may be wrapped in its own blanket and hoisted with its own petard. As we write there lies before us the account of an important meeting of the Institution of Naval Architects, at which Sir William White, K.C.B., late Chief Constructor to the Royal Navy, read a paper based on experiments conducted by Dr. Otto Schlick on the application of gyroscopic apparatus to control and limit the rolling motion of ships when exposed to the action of ocean waves. According to Sir William White, by means of a Gyroscope weighing half a ton the roll of the *See-bar*, the ship on which the experiment was conducted, was reduced from thirty degrees to one degree, without any shock or jarring of the ship. Professor Biles and other speakers pointed out that under certain circumstances the Gyroscope would increase the roll of the ship, but these criticisms are, of course, ignorant cavils. I have personally read the paper of Sir William White, and can assure my readers that they may rely on me. If sea-sickness can be conquered in Germany, why, in the name of the Eternal, not in this country, too? I have written on this subject for years, and it has not advanced the solution a scrap." This, or something like this, we may perhaps expect to read in the *Pall Mall Gazette* in the near future.

Vaccinated Veal.

Mr. Arnold Lupton has already established for himself fame in Parliament—not the fame of an orator or of a man of affairs, or for being possessed of any of the hundred-and-one qualities which are regarded with respect and esteem, but the fame of being what the French would call a *blageur*, and the English school a "rotter." For him there is felt little or no animosity, but a sort of curious interest as to what he will do next with regard to vaccination, for it is vaccination which (like King Charles' head) forms the subject matter and substratum of all his utterances. His last two attempts have been more than usually ingenious and disingenious. Of these the first was addressed in the form of a question to the President of the Local Government Board, asking him whether the "epidemic" of cerebro-spinal fever was due to blood-poisoning, and whether there was any frequently-occurring mode of introducing poison into the blood without its passing through the digestive organs other than vaccination? The suggestion that the present cases of cerebro-spinal meningitis are due to vaccination is nearly as far-fetched as the old anti-vaccination notions about vaccinated children being liable to low like cattle as the result of the bovine inoculation. The second of Mr. Lupton's efforts was made last week, and also took the form of a question, this time addressed to the Chairman of Kitchen Committee of the House, asking if any "vaccinated veal" was bought for the consumption of Members? Unhappily Mr. Jacoby was away, but the question is to be renewed after the Easter vacation. We shiver to think what the result on Mr. Lupton would be if the answer were "Yes." Perhaps it might frighten him out of the House altogether. Or is it possible that it is to his having partaken of vaccinated veal unawares that he owes the ox-like grace of his oratorical gyrations?

Eugenics in Practice.

A curious sect is said to be in existence in Chicago under the title of "The Architects," headed by an Austrian physician, Dr. Asher Gluck. The founder has laid down stringent rules for a simple life, and he declares that if followed strictly, perfect children will be born to his followers. The conditions, however, are, to say the least of it, somewhat trying. The day is divided into three periods of eight hours each, allotted to work, sleep, and study. Recreation is not provided for. Dietary excludes alcohol, tobacco, pepper, salt, tea, coffee, meat, candies or any animal product tea, coffee, meat, candies or any animal product. and women adopt men's dress. Neither shaving nor cutting the hair are permitted. They are not allowed to handle money, as they belong to a co-operative community, and any money they earn goes into a common treasury. The study is regulated by the wish of the parents for the future of their children. "If they wish him to be an artist they study art, and if a musician they must study music," and so on. Dr. Gluck is reported to claim that his new method will not only produce perfect children, but it will promote longevity, even to two or three hundred years; it will bring the human structure to a point of absolute perfection; abolish money and the competitive system in the world, and solve all social and economic problems. Curiously enough, a bride and bridegroom have been found willing to face the rigours enforced by this creed, which appears to form a strange hotch-potch of half-truths and fantasies strongly tinged with insanity.

The Polyclinic.

We are very glad to see from the report of its annual meeting that the Medical Graduates' College and Polyclinic is making such admirable progress. If it cannot be said the College fills a unique place in London medical life, it did so up to recently, but there are now two or three organised post-graduates' schools offering different advantages of one kind and another. But the Polyclinic is unique at least in that its cliniques are reserved entirely for consultation work, and patients are only received on the recommendation of their medical advisers. This is, of course, the arrangement that should be made at all medical schools, that is, if they are not to be brought into unfair competition with the practitioner outside. As it is, although the Polyclinic has no beds, it gets the pick of the clinical material of London for investigation and teaching, and this is what post-graduates want. It is sorely taxing to a man who has made great efforts, and, maybe, sacrifices, to get three months' study in London, to sit hour after hour in the out-patients' room of the hospital and see nothing but cases of anæmia in servant-girls and gastric ulcer in dressmakers, when his own practice comprises a dismally large number of similar cases. At the Polyclinic, at any rate, he will be kept constantly agog by the variety and interest of the cases. The laboratory attached to the institution is doing capital work, and the chief thing needed at present is money. No Government education grant could be given to a more directly and indirectly utilitarian object.

Sir Richard Douglas Powell has been re-elected President at an extraordinary Committee of the Royal College of Physicians of London.

Dr. H. P. Taylor, of Yell, Shetland, and his wife, have been presented with handsome testimonials by their friends and patients in the islands of Yell and Fetlar.

Dr. P. W. Kent, of Barry, was last week awarded £250 damages in an action for slander brought against Dr. Peter O'Donnell, another medical practitioner, of the same town. Dr. Kent's case was taken up by the London and Counties' Medical Protection Society.

A Clinical Lecture
ON
ARTHRITIS. (*a*)

By F. J. POYNTON, M.D., F.R.C.P.Lond.,

Assistant Physician to University College Hospital, London, and Physician to Out-Patients, the Hospital for Sick Children, Great Ormond Street.

Introductory.

In this short lecture I ask you to consider arthritis as a manifestation of diseased states and not as in itself a disease. The condition then becomes one of particular interest at the present time, for there are examples of its occurrence when there can be no doubt that it is by origin infective, and there are other examples which few believe can be so explained. No one, for instance, will dispute the nature of suppurative arthritis during the course of a pyæmia, when the staphylococcus aureus has been isolated from the arthritic exudation.

When, on the other hand, we are confronted with gouty arthritis, there is much doubt as to its nature, and some would have us believe that this arthritis is a mechanical result of the deposition of biurate of sodium in the articular structures. If we accept this explanation, then we must recognise, in arthritis, processes which range from the comparatively simple one of crystallisation to the formation of the most virulent toxins produced by bacterial growth in the human body.

It is to be expected that a minute and protracted study of infective arthritis of known origin will eventually throw much light upon all forms of joint disease. My belief in the truth of this has led me to maintain that the problem of the nature of *acute* gouty arthritis is at present better attacked by minute investigation of the processes of infective arthritis, than by theories based upon the far more difficult and less understood problems of the metabolic processes of the human economy.

Again, if our attention is confined to one such lesion as arthritis, we can the more easily keep in touch with some of the great difficulties which present themselves in general medicine.

Such difficulties, for example, as :—

(1) Determining what conditions are truly infective, and what are due not to infection but to disordered metabolism

(2) Again, in infective conditions, deciding which are the results of infection from without and which of infection from within ?

(3) Ascertaining, in an infective process, to what extent its peculiarities are dependent upon the infective agent, and to what extent upon the tissues of the individual infected.

(4 and lastly). Confining our attention entirely to the infective agent.

Investigating to what extent the *disease* is the result of the local lesions, viz., the arthritis—produced by that infective agent, and to what extent of the toxæmia caused by the poisons getting into the general system. These difficulties may be lost sight of in the difficult and complicated study of general medicine, but if we narrow ourselves down to one such lesion as arthritis, they can be very readily appreciated.

A considerable number of forms of arthritis depend upon infection from without, for example, among others, the tubercular, the pneumococcal, the gonorrhœal, those due to the streptococcus pyogenes, and staphylococci, and in my opinion also the rheumatic and some cases of rheumatoid arthritis. There are others which are uncertain. Such are hypertrophic pulmonary oste-arthropathy, "Charcot' joints," intermittent hydrops, and gouty arthritis, and the arthritis met with in colitis and dysentery. Among these there are some which are thought by many to be the result of an infection from within. Thus the pypertrophic pulmonary osteo-arthropathy, " Charcot's arthritis in colitis and some cases of hypertrophic pulmonary osteo-arthropathy are often looked upon as the result of an invasion by an infective agent, from an ulcerated colon or from a suppurating vomica in a lung.

It is correct nowadays also to lay stress upon auto-intoxication from the intestines as the cause of the gouty form, although the links in the chain of evidence are far from being complete, and it is still held by many that gouty arthritis represents an example of a condition not dependent upon infection from within or without but upon a disorder of the normal metabolism.

When we consider infective arthritis we cannot fail to see how prominent a part the infective agent takes in giving to it its peculiar stamp. Thus the ordinary form of tubercular arthritis is very different from the severe suppurative arthritis or the more transient rheumatic inflammation, and although there are exceptional cases in all these infections, we must judge of their usual effects from the common form.

Again, if we consider for a moment an arthritis resulting from rheumatic fever and an arthritis resulting from a virulent streptococcal infection, we see how in one case the general toxæmia, and in the other the local lesion comes into prominence.

The Synovial Membrane and Exudation.

It is very essential in a study of arthritis, to remember all the constituents of a joint; the synovial fluid, the synovial membrane, capsule, ligaments, bursæ, cartilages, bones, and muscles in the neighbourhood, for disease may attack them all. There is, as can be imagined, considerable difficulty in discovering with exactitude in which structure the process commences, but so far as the infective forms are concerned, the balance of evidence points to the *synovial membrane* as the starting-point in the majority of instances. The vascular supply is very considerable, and a synovial membrane in a condition of acute rheumatic inflammation demonstrates convincingly the great injection of the blood-vessels that occurs.

If the infective agent has invaded the system from some distant point—from the tonsil, for example—it is carried into the terminal capillaries by the blood stream, and, escaping, finds itself in the retiform tissue of the membrane. Anatomists point out that the synovial membranes have no perfect endothelial lining as have the pleura, pericardium, and other serous membranes, but it has always appeared to me that there is a superficial cellular layer under which the connective tissue is more retiform than elsewhere. These cells are phagocytic, and from the blood-vessels escape numerous polynuclear leucocytes which aid in destroying the bacteria. These facts seem to explain very reasonably the great difficulty there may be in demonstrating the bacteria in the synovial fluid. It is a difficulty which is prominent in acute rheumatism, but which was well recognised before this as occurring in gonorrhœal and tubercular arthritis. An increase in the synovial fluid is a very frequent and rapid response to many joint lesions, whether by bacterial infection or by mechanical injury; but an increase in the

---

(*a*) Lecture delivered at University College Hospital, London.

synovial fluid need not by any means imply that you will find numerous bacteria in that fluid. This fluid in any acute inflammation soon contains numerous leucocytes, which continue the bacterial destruction so active in the synovial membrane, and Dr. Seligmann has also brought forward some interesting points bearing upon the inhibitory action of some synovial exudations upon bacterial life—a point to which I shall again allude later. Moreover, this difficulty in demonstrating bacteria in the synovial fluid is not peculiar to human arthritis. In experimental arthritis also, it is sometimes surprisingly difficult to demonstrate the bacteria in the acute early condition or in the chronic forms, and you may meet with repeated failures. You may also meet with an exudation in which you see a few bacteria either free or in the polynuclear leucocytes, and yet the culture may be negative. I think, then, the interpretation is that these bacteria are living, or rather dying hard in a hostile fluid, and cannot rally even if put in a suitable medium outside the body.

The bacteriological results in arthritis are then uncertain, except in those particularly virulent types in which the bacteria overcome the resisting cells, destroy them, and escape into the synovial fluid destroying in that fluid also the protective cells, see fig. 1.

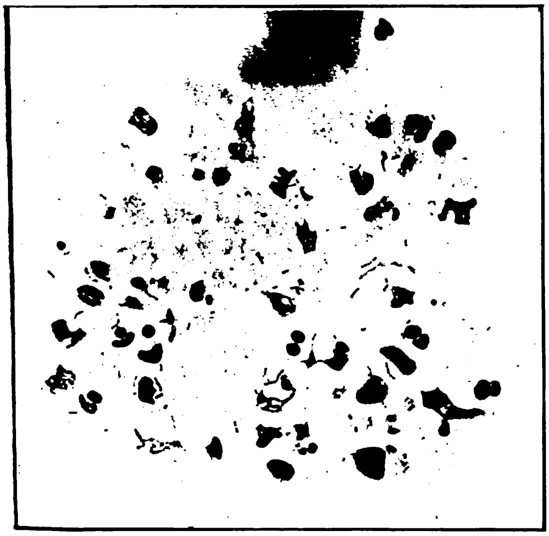

FIG. 1.

Synovial Fluid (Streptococcal Arthritis). The streptococci are present in large numbers in the exudation, and the cellular elements have been destroyed by their toxines.

When the struggle has been a severe one the condition is called suppurative arthritis, yet it must be clearly understood that this is not the most virulent toxic process. Even more virulent is that in which there is an absence of cellular reaction—dependent, as Sir A. Wright's researches tend to show, upon a deficient opsonic power in the blood—and the bacteria may then multiply in a fluid which may be almost clear. It will be readily understood from these remarks that the synovial fluid is not such a plain guide to the cause of arthritis as might at first sight be thought. It will, I think, also be clear that the correct way to study the synovial fluid in arthritis is to give as accurate an account as possible of its constituents. Such words as "septic" and "pus" are now no longer really helpful. It is not the dead cells in the pus that are harmful, but the victorious bacteria and their poisons, and as I have already mentioned, a clear fluid may mean exceeding virulence. The study of rheumatism has, in fact, been made more difficult by the rigid statement that suppuration does not occur in that disease. This gives the impression that some particular specific process, viz., suppuration, does not occur. Yet suppuration is not a rigid entity. It is on the contrary a phase of reaction to many different infections, and there are all sorts of kinds and degrees of suppuration. Among these I recognise a rheumatic suppuration, but quite admit that in rheumatic fever you do not see a staphylococcus or pneumococcus suppuration because the disease is a special disease and not the result of either of these infections.

Another cardinal point in the study of arthritis is a recognition of the fact that the great infective diseases, such as tuberculosis rheumatism, pyæmic infections and gonorrhœal infections, each and all run through various stages, one stage is more usual in one, another in another, but occasions arise in which you can trace all the stages in each disease. Take tuberculosis, for instance. Chronic tubercular disease of a joint is among the best known of tubercular lesions, but there also occur acute transitory forms of tubercular arthritis. These, so well studied by Poncet, of Lyons, have been most unfortunately named tubercular rheumatism. Yet they are not rheumatic at all but acute tubercular arthritis, and are only called rheumatic under the mistaken impression that rheumatic inflammations are always transitory.

Take rheumatism next. The most usual form of rheumatic arthritis is an acute transient process, but it would be a great mistake to think this was invariable, the contrary, indeed, is sometimes most convincingly illustrated in an acute attack. In such an attack one joint may remain most obstinately inflamed, and both bone and cartilage may be damaged, and yet the process be undoubtedly rheumatic. The ankle joint is in my experience the one most liable to differ in this way.

As a third example instance pyæmic arthritis. The characteristic condition is a suppurative one, but often one joint or possibly more will be found to contain a clear fluid. In other words the usual course of the infection is a more virulent one than that of rheumatism, and yet a transient arthritis may occur in one or other joint simultaneously with the usual suppurative arthritis.

Are we to consider the various stages in these various infections, the stage of clear effusion, for example, to mean that these fluids in the different diseases identical in nature? It would surely be a great mistake to adopt that view, and yet it is often done. The clear stage is called rheumatic, and the purulent is called septic, as if all the clear and all the suppurative processes were identical in the different diseases.

There are other conditions of the synovial exudation in arthritis which are not so well understood in part because they are not so often seen. One of these is a thick glairy exudation, which resembles unboiled white of egg. This may give rise to a very deceitful sense of fluctuation, and yet if the joint is aspirated this fluid is so thick that none of it can be got away. Such a condition is met with in the severer forms of arthritis of the rheumatoid type—as in gonorrhœal arthritis—and it may be associated with a gelatinous periarticular swelling—such cases are very troublesome and chronic.

In Charcot's disease of the joints, a condition of great scientific importance, an immense quantity of viscid fluid may be obtained from the joint. These fluids have been in my experience always sterile.

Dr. Seligmann has recently made some interesting investigations upon this curious viscid exudation obtained from tabetic joints.

He has found that it has a remarkable inhibitory effect upon bacterial growth, which he attributes to the viscid nature of the fluid rather than to any particular chemical property. In hæmophilia there may be a hæmorrhage into the joint cavity, and although one might think the sinious fluid would not do harm, it does, nevertheless, sometimes give rise to severe destructive lesions in the joint, of the type of a rheumatoid arthritis.

Gouty arthritis is characterised in some instances by an exudation which is opaque with enormous numbers of acicular crystals of biurate of soda. It is very tempting to ascribe the severe pain of gouty arthritis to the deposition of these crystals, but I think this is unlikely, for these crystals are deposited in such minute atoms that even with an object lens of $^1/_{12}$ Leiss and an high eye piece, the magnification is not sufficient for seeing the commencement of their formation. The minute size of these crystals makes me think that the pain in gouty arthritis is more probably to be explained by the sharp reaction in the gouty inflammatory processes than by the mechanical deposition of the crystals.

Joint Capsule and Ligaments.

Leaving now the subject of the synovial exudations, the next structures are the capsules and ligaments.

In acute arthritis, when the attack is a severe one, these become infiltrated with cellular and serous exudation, and their tissues thus become softened. There is considerable importance to be attached to the diagnosis, between periarticular and intra-articular swelling. The distinction is generally simple, for fluctuation is more perfect in intra-articular swelling and the outlines of the joint are more clearly mapped out. Periarticular swelling, on the other hand, is a more inveterate process. Slower in subsiding, and, therefore, more damaging to the stability of the joint.

Deformities of the most remarkable kind may, as you are aware, result from subacute and severe arthritis, and one factor in these deformities is this damage to the ligaments, for when softened they allow the powerful muscles to pull the articulating surfaces out of place and this danger becomes the more probable because the joints are often habitually flexed or extended by the patient on account of the pain.

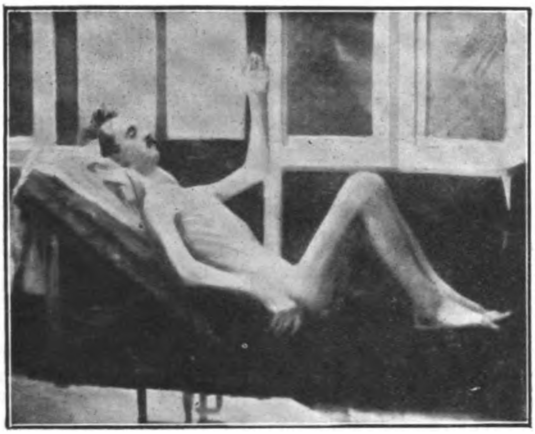

Fig. 2.

Severe Rheumatoid Arthritis, illustrating fixation of the joints in faulty positions.

The condition of the blood vessels in the capsule and the synovial membrane is also of interest. In these protracted cases there is a perivascular cellular exudation and later a perivascular fibrosis which interferes with the circulation in these structures and thus impairs the recuperative power.

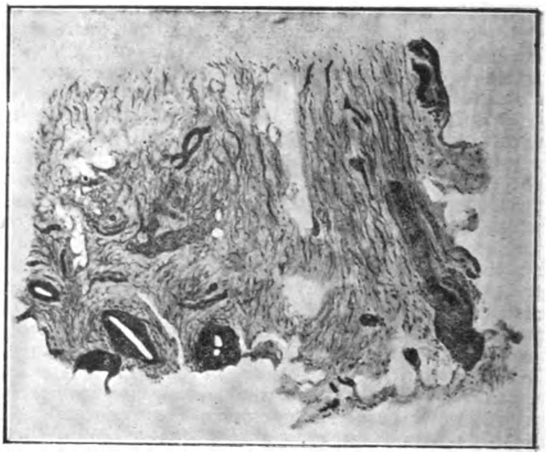
The process of damage does not even end here, for though the softened ligaments may heal, in healing they become scarred and shortened.

At all risks then, in spite of causing pain and suffering to the patient, every effort must be made to prevent this process of contraction in its early stages. Yet how difficult it may sometimes be to do this those who have to deal with them can only realise.

Much in the practical treatment of arthritis turns upon a thorough knowledge of the changes that occur in the ligaments, and serious results may occur from an imperfect acquaintance with these changes.

If, for instance, the weight of the body is thrown upon the feet when the tarsal and metatarsal ligaments are still softened by inflammation, painful flat foot may occur, or the joints may be so strained as to remain for a long time and perhaps permanently insecure.

When these structures have been much swollen and softened there will frequently be a history of much pain and stiffness in joints, lasting for a long time after the acute illness is over, and much of the success obtained at hydropathic centres depends upon the vigorous, methodical, and industrious stimulation of these structures during their convalescence.



F

A section through a part of the synovial membrane from a case of chronic rheumatoid arthritis, showing perivascular phrosis and consequent ischœmia.

The internal ligaments of the joints should be remembered, for they suffer in the same manner as do the external. An example of this would be the crucial ligaments of the knee-joint upon whose integrity depends so greatly the prevention of that backward displacement of the tibia which is so serious an occurrence.

The Cartilages.

The cartilages next require consideration. They have much wear and tear and on this account illustrate excellently the necessity there is for taking a broad view of our subject. There can be no doubt that this wear and tear tells upon even healthy cartilage when its possessor has passed many years in laborious employment, and so an arthritis in the elderly is much more liable to be accompanied by some damage to the cartilage than

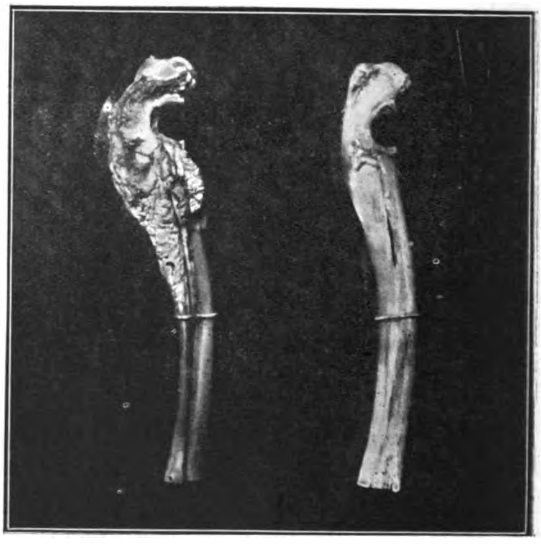


Fig. 4.

"Guttering" of bone produced by a chronic arthritis, the result of intravenous inoculation into a rabbit of the diplococcus rheumaticus.

it is in early life. The old joint throws off arthritis with more difficulty than the young joint does, and without claiming any specific process this very chronicity encourages damage to the cartilage.

Osteo-arthritis is a form in which changes in the cartilage are particularly liable to occur, and it has been thought that the process actually commences in these structures. The truth of this, however, is doubtful, yet it has a decided bearing upon the pathology of the process. If the cartilage is really damaged, the first of all the structures, it hardly looks as if these osteo-arthritic changes could be the result of an infection, for then the synovial membrane would be the first seat of damage. If on the other hand it is a disease of disturbed metabolism, it might well be that the cartilages were the first structures to degenerate. I would add that it is possible to produce changes in cartilage and a condition of joints resembling osteo-arthritis by experimental inoculations of the diplococcus rheumaticus into the veins of rabbits. Whether these changes are comparable to human osteo-arthritis it is, of course, most difficult to say, but they have also been produced by a micrococcus isolated by Dr. Paine from the knee-joint of a case of osteo-arthritis, which is an exceedingly interesting fact. Such results as these naturally incline one to think that although the first visible changes may occur in the cartilages the real commencement of the process in rheumatoid arthritis is in the synovial membrane, and lead us to believe that such rheumatoid arthritis is infective. Sometimes in chronic severe arthritis, small pieces of cartilage are separated and lie in the joint as foreign bodies. Here doubtless the difficult and laborious movements that are results of severe arthritis introduce a traumatic element which must be taken into account with the disease itself.

The presence of biurate of sodium in the cartilage of gouty arthritis is one of the landmarks in the study of arthritis. The drift of the disputes that rage around it can be easily explained.

Are these crystals the cause or the effect of the inflammation? Sir Alfred Garrod aud many authorities maintain they are the cause. There are others who think they are the effect. It has seemed to me that they are the effect and not the cause.

The biurate of sodium is located in and not on the cartilage, and I think there must first of all be change in the cartilage as Ebstein and others have maintained. In this change, delicate though it must be, it seems very possible that biurate of sodium is formed, and that it is not deposited from the fluid in the joint.

It has been noticed in gout that where the vascular synovial membrane is attached to the larger cartilages as in the knee joint, these are blood vessels which pass into the cartilage for a short distance, and in these positions biurate of soda is often present only in minute quantities. Many years ago Dr. W. Budd spoke of the urate avoiding this part of the cartilage, but recent investigations seem to me to point to another explanation. If biurate of soda is placed under the skin of animals crystals are found in the leucocytes in the neighbourhood, crystals that have been taken up as are other foreign bodies by these cells. Very possibly then the same process takes place round the margin of the cartilage in gout, and hence this relative freedom of that part of it from the crystals, depends on the blood vessels in the synovial fringe providing leucocytes which take up the crystals.

There does not seem to be anything about this presence of biurate of soda in the cartilages which negatives the possibility of some infective process starting the arthritis, and the gouty nature of the patient determining the formation of the crystals. Yet I think that if we accepted that infective processes may produce gouty arthritis and other gouty phenomena, we still do not explain in any way the *gouty disposition*, which is the chief feature of that remarkable disease.

THE BONES.

Taking the bones next. The changes differ in nature in different types of arthritis. The severe streptococcus and pyæmic infections destroy the cartilages and continue the eroding process in the bones. The severe and subacute processes, those that is to say of the rheumatoid type, also soften the bone with the result that it becomes eroded, and in addition they may induce formative processes where there is no pressure which give rise to bony outgrowths or osteophytes. Mechanical movement takes a part in causing further changes, for it is the duty of the cartilages to cope with the wear and tear of friction, but when they are destroyed the bony surfaces coming in contact are in course of time worn smooth, and the opposing surfaces become later eburnated.

When, however, the patient is bed-ridden for many years, and the arthritis exceedingly chronic, the bones atrophy from disuse and their ends become softened by the continual disease and rendered porous, so that a slight injury will produce a fracture, and if the fracture is into the joint much oily material may escape into the articulation.

A good deal of attention has been directed lately to the rarefying osteitis which occurs in rheumatoid arthritis, for even in an early stage it can be detected by the X-Rays. Nevertheless I should not lay too much stress upon these appearances as pathognomonic of a disease rheumatoid arthritis, but rather look upon them as indications of a rheumatoid type of arthritis, which may be produced by various causes, some unknown, others well known—as the gonorrhœal and some tubercular forms of arthritis.

The X-Rays again are very valuable in giving help in those cases in which a joint is stiff, and there is a doubt as to the exact explanation of the stiffness. It is essential to know whether it is due to periarticular change and muscular spasm or to fibrous ankylosis, or again to synostosis, for these questions must be answered before attempting any drastic measures for rendering a joint mobile. Recently a woman came in with her left elbow quite stiff. She had been a terrible sufferer from rheumatoid arthritis, and the X-Rays showed complete synostosis.

On the other hand a little girl came to me at the children's hospital with her right wrist joint immovable, and the photograph showed that this was the result of muscular spasm and periarticular fibrosis. In her case careful massage was indicated.

In "Charcot's joint" the destruction of bone is a very remarkable feature, and clearly points to a great lack of resistance. In spite of the failure to find any micro-organism and of the interesting observations of Dr. Seligmann, I incline to the belief that there must be some infective agent at work at some time or another in this affection, for it is just sufficiently rare an occurrence in tabes to make one think there must be some factor superadded to the primary nervous degeneration.

In gout the bony changes are not usually so extensive as in the rheumatoid conditions. Yet in chronic gout synostosis has been noted in some of the joints that have suffered very severely from the gouty inflammation—as, for example, in the metatarso-phalangeal joint of the great toe.

The bursae in the neighbourhood of gouty joints are sometimes much enlarged, the olecranon bursa is the most commonly affected, and may reach a large size and become distended with a white fluid containing innumerable crystals of biurate of soda.

BURSAE.

Passing notice must be given to Morrant Baker's cysts, which are herniæ of the synovial membrane of joints, particularly of the knee joint.

Chronic arthritis, due to tuberculosis or the rheumatoid form, may by causing chronic overdistension of the synovial cavity, thus produce these cysts.

MUSCULAR ATROPHY.

Muscular atrophy and spasm are results of severe arthritis. It is in rheumatoid arthritis that this muscular wasting is most pronounced. This wasting is not a slow process, as is the atrophy of disease, but a rapid one, and sometimes a fibrillary twitching is noticeable in the atrophied muscles. Again the atrophy is not localised to that part of the muscle near the inflamed articulation, but affects the entire muscle.

This wasting is usually associated with great myotetic irritability, and sometimes with fibrillary tremor. Triboulet has demonstrated changes in the anterior cervical cells of the cord in one such case. In some cases there is much muscular spasm, which may be so extreme as to cause the greatest suffering on any attempt at movement.

This concludes my lecture, and I hope that I have made it clear to you that there is an immense amount to be learnt and studied, with regard to arthritis, even putting aside the most important of all points, that of treatment, with which time precludes my dealing.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Arthur J. Whiting, M.D., M.R.C.P.Lond., Dean of the North-East London Post-Graduate College, Physician to the Tottenham Hospital, and to the Mount Vernon Hospital for Consumption and Diseases of the Chest, on "Acroparaæsthesia."*

CLINICAL LECTURES.

The following Lectures recently delivered are in hand, and will appear in these columns in due course. Those received from the Lecturers are hereby acknowledged with thanks. The others have been specially reported for this journal:—

Carter, Wm., M.D., F.R.C.P., LL.D.Lond., Senior Physician to the Liverpool Royal Southern Hospital, Professor of Therapeutics in the University of Liverpool. Subject: "Some Cases of Nervous Disease."

Giles, Arthur E., M.D., B.Sc.Lond., F.R.C.S.E., Surgeon to the Chelsea Hospital for Women, Gynæcologist to the Tottenham Hospital. Subject: "Developments and Dangers of Extra-Uterine Pregnancy," with illustrations.

Ormsby, Sir Lambert H., M.D., F.R.C.S., Senior Surgeon to the Meath Hospital, and to the National Children's Hospital, Dublin. Subject: "The Study of Diseases Peculiar to Children."

Palmer, Fred. S., M.D., M.R.C.P.Lond., Physician to the West End Hospital for Diseases of the Nervous System. Subject: "Friedreich's Ataxia."

Paton, E. Percy, M.S., F.R.C.S., Surgeon-in-Charge of Out-patients, Westminster Hospital, and Dean of the Medical School. Subject: "Some Observations on Intra-Abdominal Adhesions," with illustrative cases.

John Poland, F.R.C.S., Surgeon to the City Orthopædic and the Miller Hospitals. Subject: "The Use and Abuse of Skiagraphy in Fractures and Dislocations."

Raymond, F., Professor to the Faculty of Medicine, Physician to the Salpêtrière Hospital, Paris. Subject: "Abortive Forms of Tabes."

Savage, Geo. H., M.D., F.R.C.P.Lond., Consulting Physician to, and Lecturer on Mental Diseases at Guy's Hospital, Examiner in Mental Pathology, University of London. Subject: "The More Recent Treatment of the Insane."

Smith, Alfred J., M.D., M.Ch., F.R.C.S.I., Professor of Midwifery and Diseases of Women, Examiner in Midwifery, Royal University, Ireland, Gynæcologist to St. Vincent's Hospital. Subject: "Climateric Floodings," with illustrations.

Stewart, Purves, M.D., F.R.C.P.Lond., Physician to the Westminster Hospital and to the Royal National Orthopædic Hospital. Subject: "Disorders of Sleep."

Williams, Leonard B., M.D., M.R.C.P.Lond., Physician to the French Hospital, London, Assistant Physician to the Metropolitan Hospital. Subject: "Some of the Organic Consequences of High Blood Pressure."

Whiting, Arthur J., M.D., M.R.C.P.Lond., Physician to the Tottenham Hospital and to the Mount Vernon Hospital for Diseases of the Chest. Subject: "Acroparæsthesia."

ORIGINAL PAPERS.

THE REARING OF CHILDREN. (*a*)

By GEORGE CARPENTER, M.D.Lond., M.R.C.P.,
Physician to the North-East London Hospital for Children; Membre Correspondant de la Société de Pédiatrie de Paris, &c., &c.

The lecturer, in his introductory remarks, said that although four words were ample for the title of the subject, yet an hour was not sufficient time to do it justice, because it comprised the whole life history of the child, and was a vastly important one, not only to the individual, but to the nation.

He emphasized the advantages to the infant in the possession of a good heritage, physical as well as mental, on which to erect the superstructure—body. He thought it was a subject for discussion whether certain individuals—the tuberculous, the syphilitic, the alcoholic, and the degenerate—should procreate. The importance of safeguarding the material health during the pregnancy was insisted upon. He looked upon breast-feeding as the dietetic foundation-stone, and he advocated the popularizing of this function. The causes which tended to prevent this should be studied, and he looked upon the provision of food and funds to needy mothers to enable them to carry out these duties as all-important. He strongly urged mothers not to use proprietary foods for rearing infants. Failing breast-feeding, he advocated unboiled, clean, unadulterated, and tuberculous-free cow's milk, suitably diluted with water. The failure of the Legislature to assist the Public Health Authorities by the enactment of fresh laws controlling the supply to the public of a pure, unadulterated, tuberculous-free article was explained to the audience. The present unsatisfactory state of the milk trade as a public necessity, and the wholly unsatisfactory way in which milch cows are kept and milked, were also described. The Walker-Gordon Dairy Farm at Sudbury was an admirable institution, and should be imitated throughout the kingdom. Untold infant lives were, he said, sacrificed to the Demon Dirt, and the health and physique of innumerable others seriously undermined.

The diet of children at the first, second, and third years of life was gone into at length. The lecturer explained that cow's milk was still to be the standby. It was by degrees to be taken less and less diluted until it could be digested whole. During this period the motions are to be watched, and if there be curds in them further dilution is necessary.

He advocated a varied diet and the avoidance of sameness in meals. Oatmeal he considered an excellent food, which is well borne by most children. Children should be allowed water to drink between meals, but should not be given milk to quench their thirst.

Meals should be served punctually. A poor breakfast was not to be followed by an enormous lunch, and children must not be allowed to be capricious. All overloading of the stomach was to be avoided, as that was a sure way to produce chronic indigestion and its attendant evils.

Children's meals must be presided over. Some children are inveterate food bolters, while others contract the habit of dawdling; both tricks are bad, the former especially so. Dawdling over meals is not to be confounded with loss of appetite. Children must not be allowed to become fanciful; they must be made to eat what is placed before them without a murmur. Many a fight has to be fought out to a finish at the nursery table, and parents are not to be alarmed if a bad-tempered child holds its breath with rage and goes blue in the face. The child must not have its way because the mother or nurse imagines it is going to have a fit; nothing of the sort will happen. But if they be frightened by such appearances, and if they relent, worse unpleasantnesses are

---

(*a*) Abstract of Lecture delivered at the Incorporated Institute of Hygiene, Devonshire Street, W., on Wednesday, Feb. 20th, 1907.

in store for them; the child has gained a great moral victory. Mothers are advised to gain the mastery at the outset. Nor is a mother to be alarmed if a child becomes periodically sick after certain articles of diet which do not happen to please its palate. This is another childish trick which has to be nipped in the bud.

Fads and freaks about food are not to be encouraged. Little pitchers have long ears, and often remarks on the subject of diet are overheard by, though not intended for, baby brains, but which, nevertheless, make a strong impression upon them. These little eavesdroppers then become "picksome" and troublesome about their meals. A healthy child has no business to take a dislike to any wholesome article of diet; if it does, that is the fault of the mother or the nurse. A child that cannot take milk according to its mother is frequently found to digest it well enough in the hospital or private nursing-home. Children must not be encouraged to over-eat. The craving for the repetition of a helping because it is appetising must be discouraged, though hunger must be appeased. The enforcement of discipline at the nursery table is not only of educational value to the stomach, but is a very fine moral and social training for the child.

Simple sweets may be allowed in small quantities, and as a reward for good conduct; but they should never be offered as bribes. Children who are perpetually stuffing sweets, who are fed to repletion on a variety of good things at all times and at all seasons, are a horrid exhibition of parental incapacity and folly. This is a sure way to bring about disease. Bowel troubles with an enlarged abdomen, foul-smelling motions, nervous instability, and all those objectionable mental and bodily characteristics which denote the spoilt child arise from such indulgences.

To rear children properly the lecturer insisted upon the necessity for fresh air and plenty of it. Simple instructions were given for ventilating and furnishing the nurseries.

Children require at least 1,500 cubic feet of air per hour, and they are better with 3,000 cubic feet.

Carpets in the nursery are most objectionable. Skirting boards and picture rails act as dust-traps. Gas should never be used in the nursery, and burning a light at night is unnecessary and harmful. Adults and children should not occupy the same bedrooms; exhalations from the lungs of adults poisoned the atmosphere, and made the children anæmic and inert. It is necessary to have ventilation both day and night, and he advocated the top sashes of windows being opened to ensure this.

A suitable temperature at which to maintain the day nursery is 60° F., and the night nursery, 55° F.

All sanitary conveniences are best on the same floor as the nurseries, but separated from them by either a room or a passage. The sanitary fittings should be of a high order, and they require periodical inspection to ensure efficiency. He drew attention to the want of care exercised in regard to the traps, even in cases where the closet-pans are kept scrupulously clean. He objected to the bath-room and the closet being contained in one compartment. Details were given in regard to the fitting out of both closets and bathrooms, and he advocated the bath being placed in the centre of the room, or, at least, away from the wall, so that it could be readily kept clean, and, at the same time, be more get-atable for bathing purposes. He drew attention to the importance of having closet seats of the right size and of the right height from the floor. Allowing a child's legs to dangle when at stool is a sure way to produce constipation; the feet should always rest on the floor during the act.

Evacuations and soiled diapers are not to be kept in the nursery. They should be removed at once to the closet and be dealt with there.

Sleep, the lecturer said, is the most important feature of a child's life. Training to sleep should commence at birth and the infant should be placed in its cot immediately after feeding without rocking. It must not be allowed to sleep at the breast or with the teat in its mouth. He said that if an infant does not sleep naturally either its napkins are wet and require to be changed, or its clothing is moist with perspiration, and it is uncomfortable. If artificially fed the infant possibly has stomach ache, and if it be breast-fed it is very possibly hungry.

The long sleep of infants should take place between 11 p.m. and 5 a.m., so as to give the mother or nurse a good night's rest, and at the fifth month the time can be extended from 10 p.m. to 7 a.m.

Regularity of sleep for the young is as important as regularity of meals. Children require twelve hours' sleep at night and an hour or two in the middle of the day in addition. The child who is allowed to sit up night after night until 9 and 10 o'clock or longer, fails in health, becomes irritable, peevish, and bloodless, and a nuisance to himself and to others. When asleep, change of position is desirable, and children are to be accustomed to sleeping on their backs and on either side alternately.

Exercise is all important for the enjoyment of a healthy and vigorous childhood, and be it wet or fine, the daily walk must not be omitted.

East winds and north-easterly winds brace the vigorous child, though for the weakly they are not beneficial. In their cases it is necessary to temper the wind to the shorn lamb, and not to be too Spartan in one's methods. But while keeping this latter in view, mothers must beware of the opposite extreme—that of coddling.

Infants in arms should in summer be taken out of doors in the nurse's arms a few days after birth, though in winter time it is advisable not to be in too great a hurry to face the elements.

Infants require daily exercise for their limbs and bodies to keep them in good health. They should be placed on the bed in a loose garment and be encouraged to kick their legs and throw their arms about and wriggle their bodies. Even crying has its uses as an exercise for the heart, the lungs, and the chest muscles. It is not wise to try to make an infant walk because its mother thinks the right time has arrived for it to acquire that accomplishment.

If it is late in learning to walk, or, if having attempted to walk, it abandons the attempt, there is probably some physical cause underlying this inability in the shape of commencing rickets. He advocated the prevention of assuming faulty positions either at play or at their exercises.

Girls, if learning to ride side-saddle are to be placed first on one side of the pony then on the other. He was in favour of teaching children to be both-handed; there are many reasons why they should be taught to be ambidexterous.

The lecturer said the object of clothing was to protect the child from the inclemencies of the weather, and to keep the skin at an equable temperature, so that the internal organs are not flooded with blood. Clothing should be loose so as not to constrict the limbs, and restrain the free use of the muscles or hinder the passage of blood to and from the limbs. So, too, the chest and the abdomen require free play, otherwise the heart and lungs are hampered in their working. There must be no girdles; petticoats should be slung from the shoulders, and stockings should be supported by suspenders. Woollen garments should be worn next to the skin except by those who suffer from skin irritation. These children should be given silk or linen or Anglo-Indian gauze underwear and be clothed in woollen overalls.

Bare legs and knees and bare arms and bare chests are hurtful to the young.

Children are to be clad according to the state of the weather and not according to the time of the year. Fashion should not be allowed to dictate the choice of clothing; health should be the sole consideration.

Children must not be overloaded with clothes at nighttime; restless nights ensue.

Footwear was the next consideration. He advocated shoes for children—the shape of the child's foot. Boots are only to be worn under medical advice for flat feet and weak ankles. He explained to the audience the importance of not allowing the toes to be cramped together by the use of pointed shoes. Not only do such deformities arise but hammer-toes are thus made, and the big toes are thrown out of the straight and bunions form on them later on in life. He advised mothers to accustom themselves to periodically pinch the toes of their children's shoes to see that they are not being worn too short. He told them that heels and soles worn down to one side denoted weak ankles, and the doctor should be consulted. The toenails also require special attention; the nails are to be cut square, and not rounded.

Bathing is very important. There are some children who cannot tolerate cold sponging — sometimes even tub-bathing. There is no reaction; their faces become pale and their extremities cold and they are miserable and wretched for a long time after. The skin to act well must be kept in good order. There are certain cutaneous areas that require special attention, such as the prepuce. The indications for circumcision and the necessity for cleanliness of this part were clearly laid down. Not only is it necessary to keep the skin clean, but the teeth must not be neglected. Regular use of the toothbrush and periodical visits to the dentist are necessary for health's sake. Carious temporary teeth often infect the oncoming permanent set, and they must be stopped or removed. Not only are carious teeth injurious for this reason, but they lay the seeds of dyspeptic troubles, and they cause a good deal of suffering.

In regard to amusements, the lecturer said the golden rule is, never to select an indoor game if it be possible to obtain an outdoor one. He warned parents to be careful in their selection of toys and not to provide those which are likely to damage the children or their playmates. But although the number and variety of toys at the disposal of the well-to-do modern child is legion, the lecturer doubted whether the pampered minority are happier than the rustic infant making mud-pies and playing with a bundle of sticks in the precincts of the parental cottage.

No distinction should be made between the amusements provided for girls and boys. Children's lungs and limbs require exercise and those games of skill which train the hand and eye to work in unison are admirable for them. Skipping is splendid exercise for both sexes. Children at play are not to be worried about their clothes; a cotton smock-frock or overall will protect these, and make their wearers feel that they are armour-plated against a scolding.

"Nagging" is calculated to spoil a child's temper, and is a thing to be avoided. The lecturer considered the selection of a nurse a most important event in the training of children. While the mother ought herself to be the head nurse, there are numerous occasions on which the nurse must take the sole command. Mothers who devoted their lives to their social engagements instead of looking after their offspring, are not doing their duty to their children or their country.

He pointed out the attributes of a good nurse both in regard to her physical health and her moral attributes. Children are born imitators; they quickly learn both good and bad habits—the latter especially—and it is therefore very important for a mother to select the right woman. A nurse's duties are not confined to keeping her charges clean and taking them out for a walk, but she has to train them also and in addition look after their health and their happiness. The acquirement of nice habits and manners, of self-control and of many other attributes of polite society, should be learned in the nursery. To be always with children is very trying to the nervous system, and to get the full value out of a good nurse it is necessary for her to have regular off-duty periods.

Education, the lecturer reminded his audience, is not the least important feature of the rearing of children. The infant, he said, is born with certain characteristics, viz., those which he inherits from our common ancestry through remote ages and those which he has acquired from his parents and forefathers. When born into the world, other forces come into play, chief among them being the *personalities* of the mother and the nurse and training. By training it is possible to curb and eradicate the inherited bad traits and to foster and accentuate the good. It is by training that early control over the evacuations is acquired, regularity in meals and in sleep are learned, and subjugation of the desires by the will and the habits of self-control are mastered. An uninterested mother and a slovenly and irresponsible nurse cannot be expected to rear healthy children. Nor will foolish and over-indulgent parents who wait on their offspring hand and foot, produce satisfactory specimens of humanity. That is the way to grow neurotic boys and girls without a particle of self-control.

For normal healthy development of the higher nerve centres there must be quiet and an absence of all excitement and undue stimulation. It should be brought home to the masses that the early training of the child is all-important, that the child's nervous system is as clay in the hands of the potter. The production depends very much on the individual skill of the artificer.

Many of life's failures owe their want of success not so much to themselves or to their heredity as to their unfortunate early environment and to the failure of their parents and their trainers to do their duty by them.

On the other hand, many of life's successes are fashioned in the nursery owing to maternal strivings faithfully and well performed.

REMARKS ON THE POLICY WITH REGARD TO
TUBERCULOSIS,
OUTLINED IN THE REPORT OF THE VICE-REGAL POOR-LAW COMMISSION. (a)

By E. J. McWEENEY, M.A., M.D., [R.U.I.]; D.P.H. [Irel. Conj.], F.R.C.P.I.

Were my audience what is known as a "popular" one, my task to-night would be simple indeed. But such is not the case. I am addressing an assemblage of experts who are familiar with the reasons that have guided the Commissioners in framing their recommendations regarding tuberculosis, and there is accordingly no need for explanation or defence. There is left to me either criticism or what I may term "completion." For the former there is little occasion. The recommendations of the Commission are moderate, well grounded and carefully thought-out. By way of completion, I may be permitted to refer to some general aspects of the tuberculosis question, and to some of the consequences which the introduction o rate-aided sanatoria would entail.

First of all, I would like to say a word about the prevalence of tuberculosis in Ireland. In par. 102 of the Report the decrease of tuberculosis in England and its increase in Ireland are mentioned. Whilst in no wise desirous of minimising the urgency of the question, I think that the use of the word "increase" may be deprecated. The last year for which statistics are available, 1905, shows a drop of 2 (per 10,000 living) and the variation during the past forty-one years lies within the narrow limit of 5. The tuberculosis mortality in 1867 was only 1 less than it was in 1905, and that of 1880 was equal to that of 1904—the highest recorded.

What really does seem to be happening is that in the Sister Isle, the mortality from this cause is coming down by leaps and bounds, whereas in Ireland no such diminution is perceptible.

As regards the cause of this difference in the behaviour of the disease in two countries, the Commissioners are no doubt right when they say that *on our side* it is due to our not doing anything, whilst on the English side it is due to a number of changes, among which may be cited improved housing of the working class, an increasingly high standard of food and general comfort among them, and the State-regulation of dust-producing industries. Moreover they have whole-time County Medical Health-Officers who, supported as they are by public opinion, can afford to act independently of individual interests, and can accomplish much more than even the most energetic Dispensary Medical Officer in Ireland, confronted as he is with the risk of losing his popularity or imperilling his very livelihood, in the exercise of the powers with which he is invested. Whilst in no way depreciating the value of the improvements just mentioned, it is only fair to draw attention to the surprising conclusion lately arrived at by that eminent statistician, Dr. Newsholme, of Brighton, and communicated by him to the Epidemiological Society a few months ago. After an elaborate survey of all the facts and figures obtainable Dr. Newsholme concludes that the really operative factor in the decrease of the tuberculosis mortality in England is—not the several above-mentioned or any cognate improvements, but the *increased institutional segregation* of consumptives. If this be so, then a new and most powerful argument is furnished for putting into force the Commission's recommendations.

(a) Paper read before the State Medicine Section of the Royal Academy of Medicine, in Ireland on Friday, February 8th, 1907.

Turning now to the oft-debated question, "Is the sanatorium worth while?"—a question to which just now it is very important to know the correct answer, in view of the fact that here in Dublin this very week an inquiry is being held by the Local Government Board to determine whether the Local Sanitary Authorities are justified in co-operating in the establishment of a rate-aided sanatorium—I have no hesitation in declaring my belief in the efficiency of these institutions for the real as well as the economic cure of suitable cases. Let me give a few figures. From Dr. Noel Bardswell's interesting little book entitled "The Consumptive Working-Man—What can Sanatoria do for him?" (*a*) I find that 42 per cent. of all cases recover and keep their full working power for several years after discharge. The figures relating to the consumptive employés of St. James's Gate Brewery, who have been treated at the Newcastle Sanatorium, Co. Wicklow, show that about 41 per cent. are still able to work three or four years after discharge. They are classified into "early" and "advanced." and I am inclined to suppose that a somewhat large proportion of these cases were fairly advanced before entering the sanatorium.

I am under the impression, indeed, that in this country the treatment is not begun early enough to yield the best results. With increased sanatorium accommodation, and increased attention on the part of clinicians to diagnose before the bacilli appear in the sputum, I have no doubt whatever that British all-case statistics might be brought up to the highly satisfactory level attained in Germany. As an instance of what is being accomplished there, let me quote the results set forth in my recent Tuberculosis Report to the Local Government Board, as having been achieved at the Sanatoria maintained by the Hanse-Towns Workmen's Insurance Society:—

Year.	Number treated	Percentage capable of full amount of work at commencement of 1904.
1895	56	45.5
1896	146	61.2
1897	208	59.2
1898	251	53.7
1899	306	55.7
1900	296	61.0
1901	215	57.6
1902	175	65.5

These figures refer to both sexes. Those for women are more, for men less satisfactory—the universal experience.

The recommendation of the Commission that the converted workhouse sanatoria should receive not only curable but also advanced and infective cases, seems to be an excellent one. There is a most urgent need for isolation hospitals or refuges for advanced cases, whither they may be removed from their small houses or tenement rooms, and kept from infecting their families. This need is no less urgent than that of a curative sanatorium. Now, in a country where people are so much swayed by sentiment as they are in Ireland, a hospital altogether reserved for advanced and hopeless cases would, no matter how named, become a sort of byword in a locality, and the patients, even if willing for the sake of their families, to go there, would not be allowed by their relatives to enter such an institution, stamped as it would be with the brand of hopelessness. They might go, no doubt, towards the end, when the burden of looking after them would have become too heavy to bear. But the mischief would then have been done—at any rate to a large extent.

Nor do I see any grave drawback to the admission of both classes to the one institution. The most infective cases would probably be in bed, owing to temperature and weakness. It would be easy to keep them separate in an isolated ward. The advanced "ambulatory" cases could be kept at first in the same division till they had become thoroughly "broken in" to the rules for the collection and disinfection of sputum, and the prevention of air-infection from projected sputum-droplets. Their compliance with the regulations once assured, I really can see at present no valid reason why they should be kept strictly apart from the curable cases. These latter are actually destroying the bacilli already implanted within them and might fairly be expected to oppose an obstinate resistance to fresh infection. But with proper observance of the rules, there is really no reason why they should run any danger.

There is one class of patient from whom observance of rules cannot be expected—the insane consumptive. Tuberculosis is already very prevalent in our enormous, overcrowded asylums and must add considerably to the difficulties and anxieties of administration. The Commissioners suggest that all insane consumptives in the advanced stage should—in so far as their mental condition permitted—be removed from the various asylums and segregated in one or more disused workhouse sanatoria that had been specially modified for their accommodation. The recommendation seems an admirable one and I hope it will be carried into effect. Many of these patients recover, so far as concerns their mental condition, sufficiently to return home, and the experience of cleanliness, sputum disposal and fresh air which they have had in the Asylum-Sanatorium cannot but cause them to exercise a beneficial influence on their home conditions.

The proposal of the Commissioners is that the expense of converting the disused workhouses into sanatoria, and their maintenance as such, be defrayed out of special county-at-large rate. Under the existing law sanitary authorities can form joint hospital boards for the erection of infectious disease hospitals and levy a 1d. in the £ rate to support them. In view of the magnitude of the evil to be grappled with I would suggest that under the new fiscal arrangements contemplated by the Commission, the limit of 1d. would need to be considerably increased. Is a superior limit necessary at all? The natural tendency of popular bodies towards economy does not need curtailment. If the clause were made to read "not less than 1d. in in the £," it would be all the better.

If I do not altogether mis-read the "signs of the times," the rate-aided sanatorium will become a centre of popular endeavour. Among ancillary measures, more or less necessary for the successful working of these Sanatoria, may be mentioned.

(1). The Consumption Dispensary, the objects and institution of which will be found set forth in my Report to the Local Government Board above referred to.

(2). A local committee for supporting those dependent for their existence on wage-earners who are undergoing treatment in the sanatorium.

(*a*) London: The Scientific Press, 1906.

(3). A local committee for the purpose of finding suitable employment for those discharged from the sanatorium. Unless healthy out-of-door occupations can be found for such "cured" or "improved" cases, the "cure" will too often be found to be a misnomer, and the "improvement" evanescent.

The stimulus to the formation of such local Committees, or of a voluntary organisation which would take on all three functions just named, might fittingly be afforded by the only central Governmental body competent to do so, namely, by the Local Government Board, either through its medical inspectors or by lecturers specially appointed for the purpose. This is admittedly a poor country, and financial experts and a Royal Commission have stated that it is over-taxed. Poverty is probably the chief ultimate cause of tuberculosis, which is in reality nature's punishment for bad economic conditions. Could not the Treasury be induced to unloose the national purse-strings and "lend a hand" with money, co-ordination and expert advice and assistance—the essentials to successful action, and the very things in which purely local action is apt to be lacking?

Whatever be the issue of this Commission—whether its proposals are to be pigeon-holed amid the dust that covers the Reports of so many of its predecessors, and the country is to keep on sinking deeper into the slough of preventible but not prevented disease—or whether the recommendations will be put in force and form the nucleus for successful onslaught on tuberculosis—time alone can tell. Meanwhile, the Commissioners have deserved the gratitude of the country for the bold and statesmanlike attitude they have taken up in regard to this crying evil.

PUBIOTOMY: WITH NOTES OF THREE CASES. (a)

M. J. GIBSON, M.D., B.Ch.

Assistant Master of the Coombe Hospital, Dublin.

THE idea of improving the prognosis for the mother and child in cases of contracted pelvis, and of lessening the number of Cæsarian sections, inductions of premature labour and perforations of the living child, by an artificial enlargement of the pelvis, is a very old one. Symphysiotomy, first demonstrated by Courvée in 1655, was first performed on the living by Sigault one hundred years later. It was not and is not a very satisfactory operation. To Gigli belongs the honour of being the first to propose as a substitute for it an incision through the os pubis. The great danger in his operation lies in the large easily-infected incision which he employs, and this was overcome by Döderlein's subcutaneous pubiotomy, which is really a new operation. It is so simple and the results are so good that it may be regarded as one of the greatest discoveries in modern obstetrics. It is indicated in cases of narrow pelvis when the cervix is fully dilated, and when, in spite of good contractions, the head moves freely about the brim. Good contractions are a power which must always be considered because, by preparation of the maternal soft parts, and especially by good moulding of the fœtal head, many a head is driven through a narrow pelvis when we could hardly believe that such a thing could occur. The operation may be performed in cases of flat pelvis with a conjugata vera up to 6.75 cm., and in generally contracted pelvis up to 7 cm., but for these very low conjugates the head must not be larger nor harder than normal. I have adopted Döderlein's method in three cases. Its technique is as follows:—A small incision, sufficient to admit a finger, is made over the bone, usually at the left side between the symphysis, and the pubic tubercle. Döderlein's needle is passed down behind the bone and its point brought out in the greater labium. Gigli's saw is attached and the bone divided. The hæmorrhage is as a rule, easily stopped by compression. The patient should not be delivered unless delivery is absolutely indicated, but should be allowed to deliver herself. After labour is completed a few strips of adhesive plaster are put around the pelvis, a binder is applied, and the patient is kept lying on her back for twelve days. She may get up on the fourteenth or sixteenth day.

The advantages of pubiotomy over symphysiotomy are that the pelvis is prevented by the undivided soft parts from springing suddenly apart. The bladder and urethra are not so liable to injury during the operation. The operation is very much more easily and more rapidly performed. I performed my first operation on August 16th, 1906, on a 9-para, æt 34 years, who had no living child. She had had premature labour induced twice, and the pelvis generally was contracted with a true conjugate of 8 cm. A child weighing twelve pounds was delivered without difficulty. The patient was walking about on the twenty-first day. Mother and child left hospital two days afterwards in perfect health. The second case was also a 9-para, æt 32 years. Her second child had been delivered with forceps and is still alive. She had had labour induced three times. The patient came into hospital after being in labour for fourteen hours. The cervix was fully dilated, the membranes ruptured, small head free above the brim. The pelvis generally contracted, and flat with a true conjugate of 7.5 cm. The fœtal heart was 160, and very irregular, meconium coming away in large quantities. The patient had lobar pneumonia and was in a very bad condition. Pubiotomy was performed, and a six-pound child extracted with forceps, The mother had her crisis on the ninth day. Both she and her child left hospital on the twenty-fourth day in good condition. The third case was a 3-para, æt. 29 years. Her second child had been delivered alive with forceps. It weighed five-and-three-quarter pounds, and is still alive. The pelvis was a rachitic flat, with a conjugata vera of 7 cm., The child, which lay transversely was easily delivered by podalic version after pubiotomy had been performed. It weighed seven and a half pounds. All three babies were subsequently breast-fed. None of the women complained of pain or showed any difference from a normal confinement, except, of course, the second case, who was suffering from pneumonia. These three women dreaded a Cæsarean section, and absolutely refused such an operation, yet they had no fear of pubiotomy. The maternal mortality in these cases so far is about 3 per cent. In my opinion there is a great future for this operation, and it will never share the fate of symphysiotomy, but will remain for us, both in hospital practice and in private practice, a means of overcoming the difficulties connected with the lesser degrees of contraction of the pelvis without injury to the mother or child.

(a) Abstract of Paper read before the Royal Academy of Medicine, Dublin, March 8th, 1907.

THE OUT-PATIENTS' ROOM.

ROYAL FREE HOSPITAL.

A case of Dentigerous Cyst.

By Joseph Cunning, M.B., B.S., F.R.C.S.

Amongst the out-patients was a boy, æt. 9, who came complaining of swelling of the left cheek. The history of the affection was that four months before he had received a blow; swelling was noticed immediately and it had gone on increasing since. There was neither pain nor tenderness.

On examination, the skin of the cheek appeared normal over the lump and not adherent to it. The enlargement was about the size of a tangerine orange, confined to the outer aspect of the superior maxilla, definitely circumscribed and immovably fixed to it. The lump, though hard, fluctuated like a very tense cyst. On lifting the cheek there could be seen projecting above the alveolus a bluish white swelling which was the lowest part of the enlargement seen in the face. Mr. Cunning remarked that no doubt this was a tumour of the upper jaw, and he pointed out that such tumours had to be divided into those that were innocent and those that were malignant. The malignant tumour which began in the jaw itself (except in the alveolar margin) infiltrated the jaw in all directions so that enlargement could be observed in all its aspects—not only pushing out the cheek, but pushing downwards the roof of the mouth, pushing inwards the outer wall of the nose and pushing upwards the floor of the orbit. In this case, he pointed out that the only projection was on the facial aspect. The nose, orbit and roof of the mouth were unaltered.

Again, there was no trace of infiltration of the soft tissues of the cheek, the absence of which would be very unusual in a malignant tumour of this size.

The cystic character was a strong point also in favour of innocence.

The age of the patient was an unusual one for a malignant growth, but it had to be recognised that sarcomata of the upper jaw were not so very rare in children.

Then taking it that this was an innocent cyst, it had to be considered what kind it could be. The most likely was one connected with the teeth. On examination the teeth were found to be erupting in an irregular fashion—one tooth was being shed sideways, another was coming through the alveolus above a temporary one, which still remained fast. So Mr. Cunning thought this was suggestive of a dentigerous cyst (follicular odontoma). He explained that now and then a tooth was so placed that it could not erupt properly and its follicle continued secreting till quite a large sac was formed. As the follicle expanded, so the plates of the alveolus became more and more atrophied till at last no bone remained covering it. The outer wall of the antrum got pushed inwards till the cavity almost disappeared. There were other cystic swellings of the upper jaw beginning in the mucous membrane of the antrum, but these he said need not be considered in a patient of this age.

The history of this condition following a blow, he remarked, was interesting only from the fact that this probably first called attention to a swelling which, though smaller, had been present beforehand. The treatment advised was incision in the neighbourhood of the canine fossa from the mouth and removal of the lining membrane of the cyst and, of course, of the tooth if one were found in it.

The patient was subsequently taken to the theatre, the cyst opened and sponged out. A canine tooth was then found with its base attached to the top of the cyst, close to the orbital margin. The tooth and cyst wall were easily peeled out and the cavity was packed with gauze.

OPERATING THEATRES.

KING'S COLLEGE HOSPITAL.

Exploratory Laparotomy: Anastomosis Between the Upper Part of the Sigmoid Flexure and the Rectum.—Mr. A. Carless operated on a woman, æt. 60, who had been admitted to the hospital complaining of abdominal pain and diarrhœa. She had been under the observation of Dr. Tunnicliffe in the Out-Patient Department for some time, and he had come to the conclusion that an intestinal growth was present. On admission, she presented the aspect of a somewhat feeble old woman, and she stated that she had lost weight. The temperature was normal; her appetite was not good, but there was no vomiting; the bowels were opened three or four times a day, and the motions were greyish, fluid offensive and contained some mucus, but no blood. There was no discharge from the rectum or vagina. On examination of the abdomen, the patient located her pain mainly to the lower half, but there was some slight rigidity of the abdominal wall in the right upper quadrant, and a feeling of increased resistance low down on the left side. Examination per vaginam revealed an atrophic os of senile type, but the uterus appeared to be fixed. There was nothing abnormal in the rectum. On combined rectal and vaginal examination, a mass was discovered, lying between the fingers, moving with the uterus, and extending upwards, so that it could be felt bimanually. Although there was no vaginal discharge, it seemed probable that the uterus was the cause of the trouble, and it seemed possible that there was a carcinoma of the body of the uterus with secondary deposits in the iliac glands; at the same time the earlier history of the case suggested the existence of an intestinal growth, and exploration was proposed and agreed to. The abdomen was opened in the middle line below the umbilicus, and the cause of the resistance in the iliac fossa was at once determined to be the presence of scybalous masses in the sigmoid. On tracing the colon back, fæcal masses were found occupying the bowel as far up as the hepatic flexure. On passing the hand into the pelvis, a tumour about the size of a small cocoanut was found, which at first was thought to be of uterine origin. On careful investigation, however, it was discovered that the tumour had grown from the sigmoid flexure, and had dropped into the pelvis, where it had become closely adherent to the posterior uterine wall; in fact, the lowest part of the intestine was shaped like an S, with very sharp turns. The convexity of the first curve was occupied by the tumour, and from it the bowel passed upwards and took a sharp turn down into the pelvis to become the rectum, which was pushed over to the right of the middle line. An attempt was made with the patient in the Trendelenburg position to detach the tumour from the back of the uterus, but the hæmorrhage was so great that this could not be managed. It was found possible, however, to approximate the upper end of the sigmoid flexure to the top of the pelvic portion of the rectum, and it was therefore decided to short circuit the tumour by performing an anastomosis between these two portions of bowel. Mayo Robson's clamps, as used for gastro-enterostomy were applied, the portions of intestine thus guarded were brought side by side, a longitudinal incision two and a half inches in length was made through the longitudinal muscular fibres; a small strip of redundant mucous membrane removed from each viscus, and the anastomosis effected by the employment of two rows of sulpho-chromic catgut treated with iodine. The clamps were then removed, and the abdomen closed, except at the extreme lower end, where a strip of packing had to be passed down between the uterus and the growth to control the hæmorrhage which had been lighted up by the attempt to separate the two. Mr. Carless stated that the growth was probably a carcinoma of the hypertrophic variety, and the physical conditions demonstrated by the operation were quite sufficient to explain the difficulty which had been experienced in diagnosis. The displacement of the growth downwards into the pelvis and its adhesion to the posterior uterine wall were, he thought, most unusual developments, and could not be anticipated prior to operation. It was unfortunate, he said, that the growth could not be separated from the uterus, as its complete removal in this case would have been practicable owing to the laxity of the intestine above and below; it would easily have been possible to perform an anastomosis. As it was, all that could be done was to make a free passage for the intestinal contents from the lower end of the descending colon into the rectum. The actual performance of this was easy in this particular instance, he pointed out, and was carried out exactly in the same way as a gastro-enterostomy. It was probable, he thought, that the patient's pain and discomfort would be much relieved by this procedure.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Obstetrics.

Meeting held Friday, March 8th, 1907.

The President, Dr. R. D. **Purefoy**, in the Chair.

UTERUS SHOWING A FIBRO-MYOMA IN FUNDUS AND CANCER IN CERVIX.

Dr. **Alfred Smith** exhibited a specimen of above from a lady, æt. 40. He had diagnosed and discovered polypus of the uterus, and had made up his mind to remove it as the cause of the hæmorrhage from which the lady suffered. During removal he found an ulcerated spot in the cervix which proved to be an adeno-carcinoma under the microscope.

Sir A. V. **Macan** said the specimen was very interesting as showing two things which were extremely rare in combination, though neither was rare by itself.

CARCINOMA OF BODY OF UTERUS; SARCOMA OF BODY OF UTERUS.

Sir A. V. **Macan** exhibited specimens of the above. One case was that of a woman, æt. 60, who had had ten children, the last being eighteen years old. She had had two miscarriages. For two years, up to October, 1905, she had not menstruated. She then had a heavy period lasting for three weeks, after which she saw nothing until October last, when she commenced a period which continued until operation on February 14th. The other case was æt. 50, and was operated upon on January 17th.

Dr. M. J. **Gibson** read a short paper on

PUBIOTOMY,

with notes of three cases, which will be found in another column under the heading of "Original Papers."

DELIVERY BY PUBIOTOMY.

Dr. **Hastings Tweedy**, Master of the Rotunda Hospital, read a paper dealing with a case in which he had delivered a primaparous woman of a living child through an internal conjugate of 6.5 cms., at full term, by the performance of a left-sided hebotomy. Hæmorrhage had been very severe, and had resulted in a considerable degree of collapse. Delivery had to be hastened because of prolapse of the cord, which took place before the operation was undertaken. Deep lacerations of the cervix, of the soft parts lying between the severed bone, and of the perinæum, required catgut sutures. The patient's recovery was uneventful, and she left the hospital in perfect health on the ninth week with a living child.

In discussing the two papers conjointly,

Sir A. V. **Macan** said the ease with which he had seen the operation done by an operator who had never done it before, had convinced him that pubiotomy was certainly the operation in such cases as had been described by Dr. Gibson. There was nothing in it which could not be done by a man who had been through the Dublin school; and he considered it of the utmost importance that they should be able to put before the practitioner in the country the possibility of saving the life of both mother and child in cases where he had put on the forceps, but had failed, and was face to face with perforation.

Dr. **Neil** considered the operation of great importance since the risk of sepsis would be less than in the induction of premature labour.

Dr. **Alfred Smith** believed the operation had come to stay.

Dr. **Jellett** asked the communicators whether they would agree in dividing the operation into two classes: First, as the operation of election which they would select in preference to other procedures in any case in which they had reason to believe that the patient could not be delivered by forceps or her own efforts; secondly, as the operation of compulsion, where the forceps had been tried and failed. Looking at the operation from an unprejudiced standpoint, it seemed to him that in doing Cæsarean section on a perfectly healthy patient, unweakened by the long continuance of labour, they were more certain of the after results. On the other hand, he certainly agreed that, in the second class, pubiotomy had got its place and would keep it. The ease with which it was performed, the small amount of assistance required, the small extent of the wound, and the short time in performance, would be important factors in producing a small mortality.

The **President** said he could not see how pubiotomy could take the place of Cæsarean section in certain cases. He thought that its danger had perhaps been passed over too lightly. The danger of injury to the bladder had been amply demonstrated by recorded cases. The danger of hæmorrhage must, he thought, be considerable, since a fatal case had been reported from Vienna. He could not help wondering whether the locomotive powers of the patients had been satisfactory afterwards in all cases, or whether sufficient time had elapsed to enable them to judge on the point. He agreed, however, as to the value of the procedure.

Dr. **Tweedy**, in reply, said that while both symphysiotomy and hebotomy had come to stay he did not think that either would prove a perfect panacea. He had performed both operations with equal ease.

Dr. **Gibson**, in reply, said that as regards the chance of injuring the bladder, they must remember that in pubiotomy they had a great protection of the pelvis by the undivided soft parts. The bladder was never so intimately connected with the pubic bone that any tearing could result from the small amount of stretching undergone, except when owing to a previous puerperal sepsis there were adhesions between the bladder and the bone. This occurred very rarely. A French author had stated that the ends of the bone could separate up to 8 cm. without injury to the bladder or articulations. If bleeding could not be stopped by compression they could open the wound and find where the bleeding was coming from. Pubiotomy was, he believed, a safer operation than Cæsarean section up to a certain point—*i.e.*, a pelvis with a conj. vera above 6.75 c.m. The latter was better done at the beginning of labour, therefore we had no chance of seeing what the contractions would do for us, and no matter how well it was done there were cases on record where the cicatrix gave way afterwards. Both operations would unite equally well if performed aseptically, but the danger to the bladder and urethra was much greater in symphysiotomy than in pubiotomy, and the former was also a more difficult operation and therefore not so well suited for the country practitioner.

LIVERPOOL MEDICAL INSTITUTION.

Meeting held Thursday, March 21st, 1907.

The President, **Frank T. Paul**, F.R.C.S., in the Chair.

Exhibition of Clinical Cases.

A large number of cases of interest were shown. Medical cases by Dr. A. G. Gullan, Dr. A. E. Ford, and Drs. Nathan Raw and R. G. Wills; surgical cases by the President, Mr. David Morgan, and Mr. K. W. Monsarrat; skin cases by Drs. H. Leslie Roberts, F. H. Barendt, G. G. S. Taylor, MacKenna, W. C. Oram, and E. L. Anderson; eye cases by Drs. K. Grossman, R. G. Hamilton, W. E. Livsey, and A. M. Walker; ear cases by Mr. E. M. Stockdale.

The **President** showed the following cases:—

1. A boy, æt. 11, who had been scalded when two years old on the side of the chest. Subsequently the mother noticed a swelling in the region of the left pestoral muscle. This had gradually grown until it was now the size of a hen's egg. It had been examined and found to consist entirely of muscle.

2. Case of immense hypertrophy of the gums of both jaws—shown previously before the society, and now cured. The gums were removed by four operations two years ago, without extracting the teeth, and recurrence had taken place. A second series of four operations was undertaken with removal of the entire alveolar processes resulting in complete cure. Models of the original condition were shown by Mr. Phillips, dental surgeon to the Royal Infirmary.

3. A woman, æt. 53, who had received an injury to the fifth and sixth cervical nerves from a fall on the shoulder, causing paralysis of the muscles supplied by those nerves.

THE TREATMENT OF THE ACUTE PATHOGENIC INFECTIONS WITH VACCINES AND SERA.

Dr. **Nathan Raw** read a paper on the above subject. He particularly mentioned the great value of antidiphtheritic serum if given early in pure cases of diphtheria, but said that in mixed infections it did not seem to exert the same beneficial influence. He had treated 212 cases of erysipelas, puerpural fever, and other septic infections with anti-streptococcic serum, and was convinced that in streptococcal infections the serum, if given early, had a marked curative effect. The use of a polyvalent serum had immensely improved the results of treatment. In the treatment of a large number of cases of tuberculosis he had come to the conclusion that tuberculin R. had not much curative value in phthisis pulmonalis even in the early stages of the disease, but in the so-called surgical forms of tuberculosis, such as lupus, tubercular glands, joints, and peritonitis, tuberculin R. had a most marked curative effect and his results of treatment of numerous such cases was astonishingly good. He was not favourably impressed with the value of anti-tetanic serum.

Dr. W. B. **Warrington** considered anti-streptococcic serum to be of little utility in medicine, and pointed out that it was the recognition of this that lead Sir A. E. Wright to introduce the method of vaccines. He alluded to the value of endoneural injection of the anti-toxin in tetanus.

Dr. **Ernest E. Glynn**, commenting upon the very favourable results obtained by Dr. Raw with anti-streptococcic serum in puerpural septicæmia, asked what evidence there was that the cases were true septicæmia and also due to streptococci as cultures were not made in the majority of instances. Might not many have been cases of intoxication, and recovery been the result of local treatment of the uterus? Dr. Raw's success in treating lupus with tuberculin uncontrolled by the opsonic index and unassisted by light treatment was not in accord with the experience of many, for lupus was very refractory. He was also surprised that Dr. Raw had cured three cases of tubercular meningitis with tuberculin, especially as the opsonic index had not been taken.

Dr. A. S. **Parkinson** said that the earlier tuberculin was given in phthisis the greater the probability there was of a good result. He thought that the failure in advanced cases was sometimes due to secondary infection of the lungs by pyogenic organisms, and that the immunity of such patients against secondary infections should be raised as well as the treatment by tuberculin injections carried out.

The following gentlemen also took part in the discussion:—Dr. G. G. Stopford Taylor, Dr. J. Hill Abram, Dr. B. Sumner, Dr. N. E. Roberts, Dr. R. J. M. Buchanan, Dr. W. C. Oram.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Meeting held at Sheffield, March 15th, 1907.

Dr. **Croft** (Sheffield), President, in the Chair.

Card Specimens.

Dr. J. W. **Martin** (Sheffield) showed the uterus removed from a woman, æt. 60, on account of adenocarcinoma of the cervix. Microscopically, the columnar cells were undergoing metaplasia.

Dr. **Stookes** (Liverpool) exhibited (*a*) a large multilocular ovarian cyst, weighing 10 lbs., in which suppuration had occurred; (*b*) an ovary with the adherent appendix vermiformis.

Specimens.

Mr. **Cuff** (Sheffield) showed bilateral ovarian cysts with intracystic growths, removed from an unmarried woman, æt. 39. Abdominal swelling had been noticed for nine months.

Dr. **Lloyd-Roberts** (Manchester) exhibited an abdominal tumour of pelvic origin occurring in a woman, æt. 43, 22 years married, sterile. There had been eight months amenorrhœa and abdominal enlargement had been noticed for five months, latterly increasing rapidly. The tumour extended as high as the ensiform cartilage and bimanually could not be moved independently of the uterus. Abdominal section revealed a cystic tumour intimately connected with the uterus. The tumour was enucleated prior to the removal of the uterus at the level of the internal os. On section, it consisted of one large and innumerable small cysts microscopically lined by columnar epithelium.

Cases.

Mr. **Cuff** (Sheffield) communicated a case of ruptured isthmial ectopic gestation. The patient, æt. 34, four-para, had two miscarriages, each at about the fifth month. Menstruation was regular up to the last period, which was a week late. After an interval of thirty days she was suddenly seized with intense pain in the lower abdomen. This rapidly became worse. There was considerable collapse, pulse 120, temperature subnormal, respiration sighing. Abdominal section was performed within six hours of the onset of the first symptom. The abdomen contained free blood and the isthmus of right Fallopian tube was found to be the seat of an early gestation which had ruptured.

Mr. **Cuff** also related a case of uterine fibroid in a woman, æt. 35, one-para, four months pregnant, who suffered from abdominal pain and constant vomiting. The temperature was 101°, and the pulse 120, and she looked very ill. The size of the abdominal swelling exceeded a four months' pregnancy, and on the left side a hard, excessively tender swelling could be felt. It could be moved independently of the uterus, and this, together with the fact that it had increased in size, rapidly pointed to its being a solid ovarian tumour with twisted pedicle. Abdominal section revealed a uterine fibroid of the size of a fœtal head springing posteriorly from the left cornu of the uterus. Enucleation was performed and a second and smaller fibroid also removed. Superficial and deep sutures closed the uterine incision, and the abdominal wall was sutured in three layers. There was no interference with the progress of the pregnancy.

Mr. CUFF also related a case of hydrocele of the canal of Nuck.

Dr. GEMMELL (Liverpool) read notes of a case of "Early Carcinoma of the Cervix Uteri Treated by Abdominal Hysterectomy and Pelvic Dissection." Five years previously he had removed a left adenomatous ovarian cyst and right hydro-salpinx. She remained in good health until the summer of 1906, when she began to have pain in the left leg and thigh. On admission to hospital, in January, 1907, there was marked œdema of the left leg. *Per vaginam*, the uterus was the size of a three months' pregnancy, of soft, solid consistence and fixed, the cervix hard, irregular, bleeding easily. Early epithelioma of the cervix was diagnosed with fibroid of the uterus. Abdominal hysterectomy was rendered difficult by short broad ligaments resulting from the previous operation, and the presence of enlarged pelvic glands only recognised on opening the abdomen. The pelvic glands were removed, those in the obturator canal forming a mass 2 ins. long and ½ in. broad. Sections of the cervix showed early adeno-carcinoma, some of the acini being free from infiltration, definite carcinoma in the obturator and pelvic glands. The uterus contained pus and sections of its wall showed round-celled infiltration with destruction of the endometrium. The patient made a good recovery. The case demonstrated how extensive an infiltration might take place in the pelvic glands with very early disease of the cervix.

Dr. STOOKES mentioned a case of single condyloma of the cervix in a patient five months pregnant. There was no other evidence of syphilis except pigmentation of the thighs.

Dr. WALLACE (Liverpool) made a short communication, on "A Modification in the Technique of Ventrofixation of the Uterus." The subsequent occurrence of intestinal obstruction in a patient on whom he had performed ventrifixation as well as recorded cases of a similar accident in the practice of some other operators, led him to modify his procedure in the technique of the operation. He had noticed that when occasion arose for opening the abdomen in patients who had previously been subjected to this operation, a window existed in the utero-vesical pouch below the suspended uterine body. This space will sometimes admit four fingers, and through it a loop of bowel could readily pass. To obviate this, a complete peritoneal diaphragm is formed from the vesical and utero-vesical peritoneum, before suspending the body of the uterus.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, March 31st, 1907.

AT the Medizinische Gesellschaft, Hr. Waldeyar spoke on behalf of a Committee that had been formed for the purpose of erecting a monument to

THEODOR SCHWANN, ANATOMIST AND PHYSIOLOGIST, in his native city of Neuss in 1910.

Schwann was the son of a bookseller, and was born on December 7th, 1810. He studied in Würzburg and Berlin, and in 1834 went to Berlin. Here his chief works were composed. In 1839, he went to Louvain, was called thence to Lüttich as anatomist in 1848, where ten years later he became professor of physiology. In 1878, he celebrated his forty years' jubilee as teacher, and it was on this occasion that Professor Waldeyar made his acquaintance. He described the impression that his acquaintance with such a spiritual and equally modest man made on him. An account of his life was given by Henle in the *Archiv. für Anatomie und Drickios*, from which one speaker quoted. He mentioned the chief work of Schwann, which began even with his dissertation; this took up the subject as to whether the embryo, more especially that of the chick, required oxygen before the development of its blood vessels. Later he busied himself with the chemistry of the stomach, and discovered pepsin, which he was the first to prepare and name. Then he turned to decompositions and fermentations, and showed that they were associated with living organisms—studies which might be considered important precursors of those of Pasteur. Then he studied the contractile power of muscles. Then came his numerous investigations into the unity of structure of animals and plants. Here he recognised that the cells that Malphigi had seen 200 years before without recognizing their importance in life was the real elementary organism, and the egg also was nothing but a cell.

Accident would have it that in the same year, 1839, Rudolf Virchow matriculated in Berlin, whose revolutionary teaching as to the importance of the cell in pathology was built up on the discoveries of Schwann.

In conclusion, he sketched roughly the development of the doctrine of cells; how at first the cell was taken for a drop of fluid surrounded by a membrane; how Schleiden then discovered the mucous substance and the nucleus, how Schwann recognised how important the nucleus was; how he assumed for the nucleus a sort of primal progenitorship which he now disputed in the case of the infusoria, and imagined that a deposit took place around it. How then Leybig and Max Schulze recognised that the cell membrane was not an integrating constituent of the cell, and that the nucleolus was just as little an essential part; but that on the other hand the centrosoma was of importance for cell division and how the whole doctrine of generated deguidea lost ground more and more until Virchow was able to put forth his formula, "Omnis cellula e cellula," and how then the knowledge of the more delicate processes in nuclear and cell division advanced further. All this was delivered with the speaker's usual clearness and conciseness. He concluded by expressing the hope that the erection of the monument would be happily carried out.

At the Otologische Gesellschaft, Hr. Levy spoke on THE MORTALITY OF DISEASES OF THE EAR AND THEIR IMPORTANCE AS REGARDED LIFE INSURANCE.

The refusal to accept proposals for life insurance from people suffering from ear diseases was not a justifiable one. In 46,480 deaths, among 150,594 of persons whose lives were insured the mortality was only 58, or 0.04 per cent of the total of insured cases, and 0.12 per cent of the total mortality.

In 9,000 post-mortems performed during the preoperative era, there were 57 deaths from suppuration of the middle ear. The speaker had gone through the statistics of the Charitée from 1881 to 1890, and found a mortality of 0.4 per cent. from 1891 to 1905 the mortality was 0.7 per cent. Of cases of chronic suppuration, at most 2.6 per cent. died from the disease. Under these circumstances, the cases with large, non-marginated borders, with free mucoid non-smelling discharge, and showing permanently no traces of retention, should be considered as free from danger, and such should be accepted by the life insurance companies at an advanced rate. The decision as to the character of the case should be left to the expert in ear diseases.

Hr. Brühl said the question was not so much how many of the insured died, but how many were placed in danger by these ear discharges. Two years recovery after radical operation did not show definite cure as was shown by a recurrence of a cholesteatoma.

Hr. Sountog said that in Brühl's Klinik, amongst 7,794 patients, there were 632 chronic suppurations, and among these 387 were dangerous; 100 of them had been operated on. Complications occurred 23 times, 10 times intercranially. That gave a percentage of 3.7 as opposed to Hr. Levy's 2.6 per cent.

Hr. Passow agreed in the main with Hr. Levy, but his statistics proved nothing.

Hr. Lucae said the danger was increased by subjective symptoms such as giddiness, disturbances of equilibrium and pain.

Death of Exc. von Bergmann.

The death of the celebrated surgeon, as announced in the daily papers, took place in Wiesbaden on the 25th ult. No death, since that of Langenbech, has made such a break here in the surgical department of medicine, but, unlike Von Langenbech, Von Bergmann worked to the last. Only on February 27th, at the Medizinische Gesellschaft, he showed a case of sarcoma of the skull in a young woman, as reported in these columns. It was little thought then that the end was so near. The deceased was born in Dorpal in 1836, and was translated from the professorship of surgery in his native city to that in Berlin in 1882.

AUSTRIA.

Vienna, March 31st, 1907.

Post Typhoid Cholecystitis.

Reitter and Exner exhibited a patient to the members of the "Gesellschaft," on whom they had operated for a tumour in the right epigastric region, which was discovered after the patient was narcotised, the reflex action being so resistent before that time that no tumour was observed, although the patient was so emaciated and the pain so great in the left side that death appeared to be a relief. The diagnosis before this time was obscure, but gall stones were suspected. After this discovery the presumption rested on a malignant condition of the pancreas, or in the retroperitoneal gland, or, finally, a simple compression of the ductus choledochus.

Whichever it might be it was ultimately resolved to operate, and prepare for draining off the bile after opening the ductus choledochus or gall bladder. Happily nothing but an inflammatory condition of gall bladder was met with. After this the incisions were all closed and the patient recovered rapidly. and is now apparently in good health ; nothing to be found in the abdomen, while the patient is gaining health rapidly.

This morbid condition commenced after an attack of typhoid, and was probably the result of the ravages of the Eberth bacillus. Dörr, who devoted so much time to this subject found the Eberth bacillus in the gall, even in the gallstones when cut, which he cultivated and subsequently injected with the same result. In this case the bacillus was present and seems to have been the exciting cause for the cholo cystitis.

Politzer related the history of another case where cholecystitis followed typhoid, which was undoubtedly caused by the Eberth bacillus as subsequently proved. Kolisch went further, and held that cholecystitis was present at the beginning of the typhoid attack, in every case, more or less ; indeed, he considered this one of the initial symptoms in typhoid. Teleky remarked that diabetic icterus often caused a chronic inflammation in that portion of the choledochus where bile and pancreatic secretions met. Is it not possible that this change of tissues blocked the passage and subsequently produced the inflammation in the gall bladder and in this way had no causal connection with typhoid beyond the accident of time? Although the typhoid bacillus may be found in the bladder it does not follow that inflammation results from it. The bacillus is often found in other organs after typhoid, where no inflammation result. Reitter replied to the latter by saying that happily for this objection the urine was carefully examined several times for three days before the operation and no sugar or trace of diabetes to be found. As to the presence of the bacillus typhoidus and no inflammation, Teleky may be right, but when we have great enlargement of the liver, during the typhoid attack with a prior three years' history of chololitrasis it is reasonable to suspect an easy entrance by a morbid surface after a year's rest subsequent to the typhoid attack. With the changes present in the pancreas and the closure of the duct it is more than possible that the bacillus was the real cause.

Sarcoma and Morbus Basedowii.

Haim showed a case of Basedowii where he had removed a sarcoma from the upper jaw and cured the Basedowii. The patient was a lad, æt. 14, who had suffered for years with morbus Basedowii associated with a sarcoma on the right upper jaw, which had increased to such dimensions in July, 1906, that it was deemed necessary to operate. Kocker's incisions were made, the caratoid externa tied and right jaw totally resected. The symptoms of morbus Basedowii, which had existed five years, did not go down immediately, but gradually declined to the present time when no trace now remains. Under these circumstances it would be dangerous to speculate on the real cause of the recession, but it is probable that the tying of the external caratoid and the cutting off of the blood supply to the thyroid were instrumental in bringing about the change.

Sarcoma removed by Torsion.

Boese related a case of alveolar sarcoma in the scrotum that he removed by twisting the pedicle 180° and allowing it to degenerate. This method of twisting and returning the torsion was described as easy and simple.

Gangrene from Ice Bag.

Haim shewed photos of a case of abdomenal gangrene caused by applying ice to the abdomen for parametritis suppurativa. Three days after the application of the ice the gangrene commenced and ended fatally.

HUNGARY.

Budapest, March 31st, 1907.

At the last meeting of the Nagyvarad Medical Association, Dr. Adolf Erdös read a paper on

The Early Diagnosis of Pulmonary Tuberculosis.

He said that little evidence is attainable by percussion and palpation in the early stages of tuberculosis. Auscultatory phenomena while delicate, are audible to the careful examiner. An interrupted rhythm, a weakened and rough inspiration, are suggestive if found to persist over any definite area. General symptoms, even though slight, should be given careful attention. A slight hack, a constant desire to clear the throat, slight dyspnœa, a localised pleuritic stitch, an indefinite neuralgic ache in the sternal or clavicular regions, accelerated pulse-rate, capricious appetite, restlessness, night sweats, disinclination to exertion, an afternoon rise of temperature, all should be regarded with suspicion. The tuberculin test should be used in all doubtful cases in the following way (Stubb's method) :—A two-hour chart should be kept for three days before the injection. A one-half of a one per cent. solution of crude tuberculin is made in distilled water, and 2½–5 milligrams of tuberculin injected into a fleshy part of the body. A positive reaction is indicated by a rise of temperature of the previous day, headache, backache, general malaise and nausea. The local signs in the chest are exaggerated at this time. If the test is negative the injection should be repeated after a two weeks' interval, using a larger amount of tuberculin.

Dr. Revesz Vilmos read a paper on

The Treatment of Trigeminal Neuralgia.

During the acute attack it is often the best policy to resort at once to the hypodermic use of morphine, which will not only still the pain and bring the patient quick relief, but as some authors claim, it may even have a curative effect. The danger of establishing the morphine habit renders a trial of other analgesics preferable in all but the most severe attacks. Quinine in thirty to fifty centigramme doses, repeated once or twice, should be given when there is the least suspicion that malaria may be the underlying cause. Salicylate of soda stands only second to quinine, with which it may be given, and by continuing with them one of the coal tar derivatives a most effective anti-neuralgic preparation is obtained. The dangers attending the administration of the last mentioned class of remedies should never escape the physician's memory. Some doctors have confidence in gelsemium, too. Arsenic in the form of Fowler's solution is one of the most reliable remedies. Counter irritation of any kind may bring relief. An elegant preparation will be obtained by mixing in equal parts chloral hydrate, camphor and menthol. On sensitive faces this may cause blisters. Heat or electricity may also be useful. In selecting the effectual treatment for each patient there is opportunity for the exercise of much skill on the part of the physician in testing the several lines of treatment in rapid succession. Should all fail the intervention of surgery must be sought.

Dr. Ràcz delivered a lecture on

THE MORPHINE-SCOPOLAMINE NARCOSIS.

He holds the opinion that morphine and scopolamine alone are narcotic, and hardly ever safe since the dose of the former drug is too high. Small doses are, however, highly to be recommended if followed by one of the usual anæsthetics (morphine hydrochlorate 0.01 to 0.02 gm. scopolamine, hydrobromate half to one milligramme in fresh solution). Either chloroform or ether may be used, with ether the advantages are perhaps more marked. The excitation stage is shorter, less anæsthetic is necessary, salivation is never troublesome, and the danger of postoperative pneumonia is considerably diminished. Some 150 cases have been reported with a mortality of one per cent., but many of the patients were already in a moribund condition when operated on. It may also be advisable to resort to the two drugs in smaller doses in Schleich's infiltration anæsthesia.

OBITUARY.

SIR JOHN H. KER INNES, K.C.B., F.R.C.S.

We regret to record the death of Surgeon-General Sir John Harry Ker Innes, K.C.B., senior honorary surgeon to the King, at his residence in Florence, on March 12th. Born in 1820, Sir John Innes was educated at University College, London, where he qualified M.R.C.S. in 1841. He entered the medical department of the Army, and in 1854, his regiment being in India, he went to the Crimea as a Volunteer. During the Sepoy revolt in India he served with great distinction; he was wounded, and had his horse shot in the action on the Hindun, and he was present at the battle of Budli ke Serai, at the storming of the heights before Delhi, and the siege, assault, and capture of that city. In recognition of his services during the Mutiny he received the C.B., and was promoted a deputy-surgeon-general in 1858. Two years later he took the F.R.C.S. of England. Further distinction followed in 1871, when Surgeon-General Ker Innes was selected to act as British Medical Commissioner on the staff of the Crown Prince of Prussia during the Franco-German war. At the close of this campaign he received from the Emperor the Steel war medal and the Iron Cross. From 1876 to 1880 he held the appointment of P.M.O. in India, and in 1878 was appointed an honorary surgeon to Queen Victoria, retiring in 1880. He was given a K.C.B. in 1887, and on the death of the Queen was gazetted to the appointment he held at his death.

SPECIAL ARTICLE

THE PLEA OF INSANITY IN THE SCOTCH POISONING CASE.

A trial for murder, which has excited considerable interest by reason of the unusual issues raised, was concluded in the Court at Edinburgh last week. The facts are as follows: Last November, a Miss MrKerson, housekeeper to a Mr. Lennox, partook of a cake of shortbread which had come by post to her master, and immediately thereafter manifested symptoms of strychnine poisoning and died in the course of a few hours. Suspicion fell on a retired colliery manager, Brown, as the sender of this cake, and he was duly arrested and brought before the Sheriff. The fact of strychnine poisoning, and the fact that the drug was contained in the icing of the cake, which had obviously been put on by an unskilled hand, was not in dispute; the only question was whether Brown was the perpetrator of the crime. On the prisoner's appearance before the Sheriff, the Procurator Fiscal produced certificates from Brown's own medical adviser and from Dr. Carswell, Glasgow, to the effect that he was a subject of chronic epileptic insanity, and in respect of this the Sheriff did not ask him to plead, but reserved the matter for trial at the adjournment. Accordingly, when Brown was brought before the Court of Justiciary, a curious state of matters arose. As a preliminary, it had to be settled whether he should be allowed to plead, or whether he was to be regarded as insane. The Solicitor-General, prosecuting, asked the Court of five judges to find the prisoner insane—which would, of course, have put an end to the whole matter, and prevented the case from coming before a jury at all; while the prisoner, through his counsel, appealed for trial on the ground that he was sane and competent to plead. The Lord Justice General decided that the case should proceed. He pointed out that where insanity is established and it would therefore be useless to allow the prisoner to plead, the Court has been accustomed to ensure the public safety by relegating the prisoner to confinement until further orders, while under the Lunacy Act of 1857 there is a provision that where any person charged with crime is found insane he shall be kept in custody during his Majesty's pleasure.

The case thus came before the Lord Justice General and a jury, and the evidence was entirely circumstantial. The facts of poisoning were not in dispute, and the Crown was able to trace all Brown's movements on the day of posting, and to show that he could have procured and dispatched the shortbread on the day in question. The main piece of evidence, on which the whole guilt practically hinged, was the question of whether the address was in the prisoner's handwriting. So far, then, the case of the Crown was rather thin. They produced, however, undoubted evidence of the prisoner's insanity: he had had to give up his business as colliery manager because he became unfit for it; neighbours regarded him as peculiar; he had grandiose and other delusions and he was notoriously an epileptic. Dr. Carswell swore that he was suffering from chronic epileptic insanity, and his own medical attendant averred that he would have been prepared to certify him as a lunatic at any time within the past year or two. The defence was limited to pointing out the incompleteness of the circumstantial evidence, and no medical testimony to the prisoner's soundness of mind was forthcoming. Lord Dunedin, besides being the head of the Scottish bench, is universally recognized as one of the ablest lawyers in the kingdom, and his charge to the jury is full of interest. After pointing out the unusual nature of the case, his lordship went on to say that the 87th section of the Lunacy Act of 1857, under which the case proceeded, used the word "insane." In one sense, no one could say what insanity is. He did not think that any doctor learned on the subject, would agree to a definition. What might be called scientific opinion upon insanity had greatly altered in the course of years, and the courts of law were bound to follow so far as they could the discoveries of science, and alter their definitions and rules along with the experts. His lordship then went on to explain that minor epilepsy robbed the patient of the full control of his faculties yet left him free to act, not, as he (his Lordship) thought, automatically, but free to act, it might be, of set purpose, but yet a purpose which was not controlled by a rational and sane will. He then referred to the absence of medical evidence for the defence, and spoke in high terms of the testimony of Dr. Herbertson, the prisoner's medical man, who seemed to him a very eminent example of that typ of country practitioner of whom they might well be proud. His evidence apparently impressed the judge greatly, as also did that of the other Crown experts. His Lordship then charged the jury *first* that they must consider the prisoner's present mental state, and, if they came to the conclusion that the ravages of disease were such that the prisoner was not in the same condition that a sane man would be, and that he was not able to tell about his actions, then they were bound to state he was insane, and not to proceed further. If they did proceed, the next point in order was whether the prisoner sent the poisoned cake. The one direct point in evidence was the address label, but he did not say it was impossible for the jury to be very sure in their own minds. Thirdly, if they answered the question affirmatively they had again to consider whether the prisoner was at that time sane or insane. The jury returned a verdict, by a majority, that the prisoner was now insane, and his lordship subsequently told them they had arrived at a perfectly right one in the circumstances.

The case seems noteworthy on two points—first, the peculiar procedure which involved the prosecution trying to prove insanity; and, second, the extremely lucid summing up by the judge of a very difficult question of responsibility. He definitely lays down what medical men are thoroughly familiar with—that an epileptic may under an insane or epileptic impulse perform purposive acts, and yet that he may in all good faith entirely forget all that has happened. Lord Dunedin thus shows himself much more willing to take up an advanced view of insanity, corresponding with what modern science teaches, than many of his other brethren on the bench.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

BELFAST.

County Down Infirmary.—The annual report of this hospital for last year has just been issued, and shows that 539 patients were treated in the wards during the year. The average number of beds daily occupied was 47, and the average cost was 2s. 5¾d. per day per patient. Dr. T. M. Tate makes special reference to the treatment of tuberculosis. The number of patients admitted to hospital who were suffering from tubercular affections was 16.6 of the total admissions, and though, as he says, anything they can do will only deal with a fractional part of the great problem the prevention of tuberculosis, he believes it is their duty to do what they can to treat these cases in the best way known to modern science. To this end he urges the further provision of outdoor shelters, a small number of which have already been provided for men, on most suitable ground generously given at a nominal rent by Lord Dunleath. He looks forward to the county authorities taking up this matter at no distant date, and providing proper sanatoria.

Royal Victoria Hospital.—The annual meeting of this hospital was held last week, the Lord Mayor, the Earl of Shaftesbury, K.C.V.O., in the chair. The report showed that the number of patients treated in the wards during the year was 3,280, and in the extern department 27,626. The daily average of beds occupied was 218.2, but there are still 64 beds not in use owing to lack of funds. There were 1,384 surgical operations, with 44 deaths after them, giving a mortality of 3.17 per cent. Excluding the cases moribund on admission, the mortality in the medical wards was 4.26 per cent., and in the surgical wards 4.54 per cent., the average mortality in all wards being 4.42 per cent. One sentence in the report of the Committee (not the Medical staff) will be noted with pleasure by the general practitioners of Belfast:—"The subject of hospital abuse, and the ever-increasing numbers to be attended to in the extern departments of hospitals has been prominently before the public of late, and must undoubtedly be tackled in the near future if patients seriously ill are to have the time and care given to them that the nature of their illness renders imperative." Dr. H. L. McKisack, the honorary secretary of the medical staff, in moving the staff report, referred specially to the medical school, and the benefit which the hospital derived from its association with it.

Cerebro-Spinal Meningitis.—Each day during the week a few new cases have been sent to the Purdysburn Fever Hospital, but on the whole the numbers are less than before, and there is some reason to hope that the epidemic is abating. A good deal of dissatisfaction and criticism have been aroused in medical circles by the neglect of the authorities, and specially the Medical Officer of Health, to report on the various sorts of serum which have been tried in the treatment of these cases. It is known that a quantity of serum was obtained from Berne, and it is believed that another lot was got from one of the London hospitals, and a third variety, which is said to have been the only one found of any use in Glasgow, from a large firm of manufacturing chemists in England. It does not seem to be much to ask of the Public Health authorities, in view of the importance of the matter and the amount of public anxiety aroused, that they should report at the earliest possible moment as to results, whether positive or negative, obtained by the use of these medicines.

LETTERS TO THE EDITOR.

THE RIDEAL-WALKER COEFFICIENT.

To the Editor of the Medical Press and Circular.

Sir,—We ask a few lines of your space to state that it has been found necessary to substitute the term "Rideal-Walker Coefficient" for that originally introduced by us, viz., "Carbolic Acid Coefficient," owing to the abuse of the latter on the part of unscrupulous manufacturers and vendors.

The necessity for adhering strictly to the *modus operandi* prescribed in our test has been strongly emphasised in the last two or three years since we published our method, and that this caution is necessary is shown by the fact that many disinfectants are advertised as having a certain "carbolic acid coefficient" when the figure given has obviously been obtained by methods having little or nothing in common with the test as described in the *Journal of the Royal Sanitary Institute*,* thus introducing confusion and robbing the term of the value it originally possessed.

Much of the success of our method is due to the fact that we provide for the postulant and control being tested not only *in* the same time but *at* the same time. As the resistance of the test organism, even when sub-cultured from the same stock, varies from day to day, it is unfair and misleading to offer a "coefficient" obtained by testing the postulant on one occasion and the phenol control on another.

Similarly, when the "Thread," "Garnet," or any modification of the Rideal-Walker test has been employed, information that such a method has been used should accompany the "coefficient," and the latter should certainly never be advertised without this information.

It is therefore most desirable that bacteriologists when reporting on the germicidal value of a disinfectant should specify *precisely* the method employed. Great discredit has been thrown on the Rideal-Walker test by the publication of results obtained by the worker modifying the technique—sometimes to a very large extent—without notifying the modification, and many of the discrepancies referred to by critics are directly attributable to this fact.

We are, Sir, yours truly,

Samuel Rideal.
J. T. Ainslie-Walker.

The President of the Local Government Board has appointed Mr. J. M. Hamill, M.A., M.B., B.Sc., Assistant Inspector of Foods in the Medical Department of the Board.

* Vol. xxiv. Part III., 1903.

REVIEWS OF BOOKS.

COLLECTED PAPERS BY SIR LAUDER BRUNTON. (*a*)

DEDICATED to Ferrier and prefaced by an interesting introduction telling of the author's early struggles in connection with his researches, this volume will be welcomed by everyone interested in the scientific aspects of practical medicine. No one, perhaps, has done more to advance our knowledge of remedies than Sir Thomas Lauder Brunton. His name will always be associated with amyl nitrate and its great service in cases of cardiac angina. The publication of this series of papers, some of them dating back to the sixties, affords a record of work of which anyone might be justly proud. Most, if not all, of the papers are familiar to everyone who makes a specialty of materia medica and therapeutics, and therefore in re-reading them in this collected form one feels that he is merely renewing his acquaintance with old friends in new guise.

Such a collection possesses a special value for the general reader, because the papers are arranged in definite sequence, which is, of course, impossible when they are read individually, scattered as they are throughout a wide range of scientific literature. No one appreciates more the usefulness of the collected writings of such an eminent scientist as Sir Lauder Brunton than original workers who must frequently refer to the teaching and experience of others. They have, however, a wider sphere, for they appeal to every up-to-date practitioner who is bound to realise that the true basis of all practice must rest upon scientific investigations, such as are described in the work under review. Empiricism in medicine would soon be abolished entirely if more real work were done on the lines laid down by the author of these valuable papers. No worker has excelled him in diligence and care, and few have equalled him. His painstaking efforts are marked on almost every page, so that the reader is enabled to rely absolutely on every statement made, knowing that it has been given as the result of the most elaborate and thorough research and observation.

We shall await with much interest and expectation the publication of the subsequent series of papers, and meantime we commend the present collection as a valuable addition to the scientific practitioner's library, not merely as a reference volume, but as a stimulus to original observation and study in the practical and scientific aspects of this work.

THE PRACTICAL MEDICINE SERIES. (*b*)

IT is often, no doubt, a distinct advantage to the busy practitioner to have an epitome of the year's work in every department of medicine prepared ready to his hand. Such an epitome, however, to be of any real service must be well made. We fear we are unable to say this of any of the volumes before us. The summarising appears to us to have been made on no very definite plan, much that is quite of passing interest being included, and many facts of importance entirely passed over. We regret that we have been unable to find much to commend in these volumes. In fact, the editors have attempted a highly delicate task, and the result, we fear, from the practitioner's point of view must be regarded as leaving much to be desired. Such a series could never fully replace the reading of medical journals, or the excellent abstracts given in many of these from week to week.

Should this series be continued we would strongly urge the editor to enforce upon his collaborators the necessity for more judicious selection of their material and for very thorough pruning and condensation before it is put in print. Such books as these might possibly serve a useful purpose were they worked out on a definite system, and were they to contain the essence and the cream, so to speak, of the year's literature on any single subject. As they stand, their usefulness to British medical men will be found to lie chiefly in the fact that they give the experience of their American colleagues practising in the various specialities. So that if the series were made thoroughly representative of all that is best in American medicine for each year, it might be of real help and value. The idea is good, but its execution might be considerably improved. We think the success of the "Practical Medicine Series" lies rather in its promise than in its performance. The binding and get-up of the volumes is not very elegant.

SWANZY ON THE EYE. (*a*)

THIS excellent handbook has reached its ninth edition and has been very largely re-written. It now appears under the joint authorship of Mr. Swanzy and Mr. Louis Werner. The work is brought well up to date, and there are a good many changes to be noted. Perhaps the first is the large number of new illustrations which have been added, and very good ones they are. These account, according to the preface, for the increased size of the book by about 60 pages; but on the other hand we note that the references to literature (formerly given at the end of each chapter) have been left out, though a few are given in footnotes. This is hardly an advantage. The theory of the ophthalmoscope, the optical structure of the eye, refraction and accommodation are more fully treated than in previous editions, and a chapter on elementary optics has been again inserted. A new section has been added on the bacteriology of the conjunctiva, and Parinaud's conjunctivitis is well described, but no hint of its rarity is given. In the chapter on the uveal tract a radical departure from generally received views may be found in the statement that, excluding syphilis, "tubercle is probably the most common cause of iritis" (p. 353). Most ophthalmic surgeons, in this country at all events, would, we think, demur to this statement, unsubstantiated as it is by any statistics in the work before us. Another new feature is a much needed description of heterophoria and the various tests, &c., for it.

Misprints are few and far between, though the dual authorship is perhaps shown by the varying spelling of hypopyon, which occasionally appears as hypopion. For a book of its present size, "Swanzy on the Eye" can hardly be surpassed, but the pages in each edition are becoming more numerous, and, we may presume, the students' task more onerous.

TREVES' "OTHER SIDE OF THE LANTERN." (*b*)

A FINE popular edition of Sir Frederick Treves' book of travel has been issued by Messrs. Cassell and Co. "The Other Side of the Lantern" professes to be an account of a "commonplace tour" round the world. Certainly the book itself is not commonplace, for it is crammed from cover to cover with sharp, incisive observation and no small amount of literary power.

(*a*) "Collected Papers on Circulation and Respiration." First Series, chiefly containing Laboratory Researches. By Sir Lauder Brunton, M.D., D.Sc., LL.D., F.R.S., F.R.C.P., Consulting Physician and Late Lectures on Pharmacology and Therapeutics to St. Bartholomew's Hospital, &c., &c., London: Macmillan and Co., Ltd.

(*b*) "The Practical Medicine Series for 1906," in nine volumes:—Vol. III., The Eye, Ear, Nose and Throat, edited by C. A. Wood, M.D., A. H. Andrews, M.D., and G. P. Head, M.D.; Vol. IV., Gynæcology, edited by E. C. Dudley, M.D., and C. von Bachelle, M.D.; Vol. V., Obstetrics, edited by J. B. De Lee, M.D., D. Rochler, M.D., and H. M. Stowe, M.D.; Vol. VII., Pediatrics, edited by Isaac A. Abt. M.D.; Orthopædic Surgery, John Ridlon, A.M., M.D., and Gilbert L. Bailey, M.D.; Vol. VIII., Materia Medica and Therapeutics Preventive Medicine, Climatology, Forensic Medicine, edited by George F. Butler, Ph G., M D., Henry B. Favill, A.B., M.D., Norman Bridge, A.M., M.D., Daniel R. Brower, A.M., M.D., LL.D., and Harold N. Moyer, M.D.; Vol. IX., Anatomy, Physiology, Pathology Dictionary, edited by D. A. Evans, M.S., M.D., Adolph Gehrmann, M.D., and William Healy, A.B., M.D. Chicago: The Year Book Publishers, 40, Dearborn Street. Agents for the United Kingdom, Messrs. Gillies and Co., Glasgow.

(*a*) "Diseases of the Eye and their Treatment." By H. R. Swanzy, A.M., M.D., (Causa hon.) Univ. Dublin, President of the Royal College of Surgeons in Ireland, Surgeon to the Royal Victoria Eye and Ear Hospital, etc., etc., and Louis Werner, M.B., F.R.C.S.I., Ophthalmic Surgeon to the Maternity Hospital, Assistant Surgeon to the Royal Victoria Eye and Ear Hospital, etc., etc. Ninth Edition. Pp. xx. and 744. 12s. 6d.

(*b*) "The Other Side of the Lantern." By Sir Frederick Treves, Bart., G.C.V.O., C.B., LL.D. Popular Edition. London and New York: Cassell and Co., Limited. 1906. Price 6s.

From the technical point of view of the author's craftsmanship, we should say that the book would have gained by the omission of part one, consisting of twenty-eight pages of a kind of prologue, in the course of which the reader is conveyed from Tilbury to Aden. The descriptive style of the writer is terse and graphic. It would be difficult to compress more substance into a few words than in the following picture of the famous Kashmir Gate at Delhi :—" The parapet of the gate," it runs, " has been much battered by shell, and its outer walls are pitted in a hundred places by shot from English guns. The place is haggard with grim memories. The ditch is spanned by just such a bridge as spanned it in '57, but the depth of the fosse is diminished, while its sides are less rugged than they were." The gem of the whole book, to our mind, is Chapter XVII., which describes " The Garden of the Unforgotten." Indeed, one lays down this book with the conviction that Sir Frederick Treves would as a writer have made a name no less distinguished than that he has attained as a surgeon. The book contains forty illustrations from photographs made by the author. These illustrations many of them display fine artistic insight in their selection, and some of them—notably that of the " Garden of the Unforgotten," are pictures of unrivalled excellence and beauty. All medical men should possess this book.

SAINSBURY ON THERAPEUTIC PRINCIPLES. (*a*)

A TRUE conception of science is one of the greatest needs in the quest for clear thought at the present day. An inventory of facts, however carefully set in order, is not itself science, any more than a dictionary is literature, or a table of dates history. They are useful in their proper places, but they must not be taken for what they are not. Accuracy is a prime virtue, it is true, in science as in history, but mere accuracy of statement does not constitute either science or history. For science there must be, if the facts permit it, the broad sweep and the full survey, the general, and not merely the mass of particulars. The wood must be obvious, and not merely the trees. The parts must stand to each other and to the whole in proper harmony, and the whole be in harmony with its neighbours. In a word, only when the standpoint becomes philosophical does a group of facts become science.

In this sense, Dr. Sainsbury's book is one of the most scientific which has come under our notice for a long time. To the medical reader, jaded with indiscriminate facts from the perusal of the books which form the bulk of medical publications, the present volume is like the shadow of a rock in a weary land. There is no hurry here ; there is no attempt to impress the reader with the multiplicity of the author's knowledge, but there is meditative disquisition, calm, careful reasoning, and lucid, even distinguished manner of expression.

Dr. Sainsbury discusses the first principles of therapeutics, and he applies them to the facts of health and disease. He will be a dullard who comes away without many new ideas in his mind, and without many new points of view open to him. It must not be supposed, however, that the book is unpractical. Many details are discussed, but they are discussed relatively, and not absolutely. Thus, not only diet, atmosphere, surroundings, the nurse, the attitude of the patient, offer food for reflection, but the uses of the various classes of drugs in the *materia medica* are explained, rather, it is true, by suggestion and illustration than discursively. There are doubtless individual points of view in Dr. Sainsbury's book with which various readers may quarrel. For ourselves, we feel grateful for much pleasant and leisurely reading, and we commend a book which is at once literature and science.

(*a*) " Principia Therapeutica." By Harrington Sainsbury, M.D., F.R.C.P. London: Methuen and Co. 1906. Pp. xi. and 244. Price 7s. 6d. net.

LACK ON DISEASES OF THE NOSE. (*a*)

THIS book is somewhat unevenly written, parts of it are extremely good, while others are rather the reverse. The chapter on nasal obstruction will well repay perusal. The relation of nasal to oral pathology and the way in which affections of one cavity act and react on another have only within recent years received attention. The effect of dental disease on the nose has been fairly well investigated and is fairly generally known, but the effect of nasal obstruction on the growth and health of the teeth is still very imperfectly appreciated, and this most important relation is well expounded in Mr. Lack's book. The treatment of chronic sinus suppuration is discussed on rather antiquated lines ; one would expect less stress to be laid on drainage as the ultimate aim in the performance of radical sinus operations. We cannot agree with the statement that it is useless to try examination of the antrum by direct illumination during the radical operation ; in our judgment the only way of securing accuracy in such operations is by inspection during the operation with the forehead lamp.

Numerous operations for the treatment of deflected septum are given, most of these are entirely out-of-date, their place having been taken by the sub-mucous resection. The author's criticism of this elegant operation is, in our opinion, unjust. With an experience of more than a hundred such cases we have never seen subsequent sloughing, and inconvenient hæmorrhage during operation is very rare. It is never necessary to use a general anæsthetic. That there is a certain amount of difficulty in its performance is, of course, true ; but no one with any pretensions to being a rhinologist would have such difficulty in carrying it out as Mr. Lack states. The book is well, if not profusely, illustrated, and is, on the whole, a useful addition to the literature of the nose.

THE ELIMINATION OF THE UNFIT (*b*).

THE poor, in mind and body as well as purse, are ever with us. Would-be reformers talk glibly regarding " degenerates " and " defectives," but we are still far from understanding the ætiology of these " regrettables," and while many advocates are loud in their advertisement of preventive and curative measures, the rational medico-sociologist hesitates until the day dawn of scientific truth shall have afforded sufficient light to indicate the right path which should be travelled.

But Dr. Reid Rentoul is not among these halting and hesitant ones. He is a bold thinker and a brave writer, and lacks not either in the courage of his convictions or in a pungent power of expression which is often more forcible than scientific. It is interesting, but not surprising, to learn that " no less than eleven—apparently respectable—publishing firms could not see their way to publish the first edition." In these pages there is a ghastly catalogue of the physical deterioration, mental degeneracy and general decadence of our people. Truly, the list is a terrible one, but statistics on which Dr. Rentoul depends for most of his contentions require much more careful handling than they receive in these impetuous pages if their full truth and complete meaning are to be revealed. With much of the author's denunciations and demands we have considerable sympathy, and can only regret that he has weakened his case both by extravagances of expression, and an, at times, most offensive lapse into vulgarisms and an employment of inexcusable expletives. The work is one which must be studied with much discrimination, and for many of the so-called facts here presented we would like more precise and authoritative evidence. It is evidently written for the the ordinary layman as much as, or perhaps more, than

---

(*a*) " Diseases of the Nose and its Accessory Sinuses." By H Lambert Lack, M.D.Lond., F.R.C.S., Surgeon to the Throat Department of the London Hospital, Surgeon to the Throat Hospital, Golden Square, etc. Pp. 399 and xv. With 124 illustrations. London: Longmans, Green and Co.

(*b*) " Race Culture, or Race Suicide ? " (A Plea for the Unborn). By Robert Reid Rentoul, M.D. Pp. 182. London and Felling-on-Tyne: The Walter Scott Publishing Co., Ltd. 1906. Price 7s. 6d. net for the medico-sociological student. Dr. Rentoul's specific for the ills that afflict us from the presence of "mental degenerates and physical deteriorants," as he terms them, as either voluntary or compulsory sterilization: "The operation consists in excising and ligaturing the divided ends of, in the male, the vasa deferentia, or spermatic cords, and with female, the fallopian tubes." Some interesting points are discussed as to the effects of sterilization upon the sexual characteristics and general health upon "the patients." Really Dr. Rentoul's proposal is under present conditions of civilized life in a Christian country so impossible, and from some standpoints, so risky, that it is hardly likely to receive that consideration which he considers it to merit. The book in spite of its egotism, its many objectionable features of style and diction, its looseness of argument and lack of logical arrangement, is nevertheless full of speculative interest, and is not deficient in suggestiveness, and the subject dealt with is clearly one of such pressing racial importance that no rational proposal should be neglected. We cannot but think that the very title of this book is indicative of its unsatisfactory inconclusiveness.

AN EGYPTIAN HEALTH RESORT. (*a*)

Egypt is for many reasons a peculiarly attractive land for the tourist and health seeker. During recent years, means of transit, hotel accommodation, and all the many needs and necessities of the invalid and traveller have been improved, so that the Land of the Pharaohs is now one where medical men may send patients with a guarantee that adequate provision will be available. Dr. Hobson's manual is an admirable guide which may be consulted with profit by both physician and patient. It describes the manner of access to Helonan, the special features of the place, its baths and mineral waters, and deals with many other matters, such as amusements, places of note in the neighbourhood, the flora of the district, and much general information likely to be of real service. The illustrations are excellent. No one should set out for Egypt without this guide-book in his hold-all.

THE RIVIERA OF PORTUGAL (*b*).

Portugal is but little known to most English medical practitioners. Dr. Dalgado's *brochure* is intended to quicken interest in the Portugese Riviera, and to show that Mont' Estoril is a desirable winter station, and Ciutra a charming summer resort. Much valuable meteorological and climatic data are here collected, and numerous particulars likely to be of service to the tourist and health seeker. There is no map, which is a regrettable deficiency to such a monograph as this.

PHILLIPS ON GYNÆCOLOGY.

This work on gynæcology was published first in 1893, and since then has passed through three editions. The present, the fourth, edition is said in the preface to be "revised." In addition, a more detailed account has been given of Chorion-Epithelioma, and the operation of Ventro-Suspension. The literature appended to many of the chapters has been carefully altered and kept up to date.

Discussing the treatment of myomata, the author tells us that removal of the ovaries "is indicated in young women with slowly growing hæmorrhagic fibroids, interstitial or sessile subserous in variety, and where the level of the tumour does not reach above the level of the umbilicus." Hysterectomy "is the last resource for the patient." "There is a growing feeling in favour of it" (intra-peritoneal hysterectomy) "as compared with the extra-peritoneal operation." "The relative value of supra-vaginal amputation and total extirpation" (in malignant disease of the cervix) "is at present not decided." Such statements scarcely prove that a careful "revision" took place.

The revised references to literature at the end of a chapter on "Affections of the Uterus" respectively refer to communications published in the years 1898, 1886–7, 1897, 1885, 1898, 1885–6, 1885–6, 1888, and 1885. The author apparently does not think that here at least there is any scope for the "advances of gynæcology" to which he refers in his preface. The fact is the book is incapable of revision, and for this reason we regret to see a new edition of it.

DORLAND ON WORDS. (*a*)

This very excellent dictionary of medical and scientific terms has been thoroughly revised and brought up to date. Over 2,000 new words have been added, and numerous improvements have been made throughout the text. Six new coloured plates have also been added illustrating appendicitis, diphtheria, gall-stones, Leishman-Donovan bodies, measles and nephritis. The dictionary is a most complete one, and at the same time it is handy in size, whilst its appearance is all that could be desired.

MEDICAL NEWS IN BRIEF.

Medical Graduates' College and Polyclinic.

The annual general meeting of the Medical Graduates' College and Polyclinic was held on March 22nd at Chenies Street. Dr. C. Theodore Williams presided. Captain Hayward Pinch, the medical superintendent, read the annual report, which stated that there were now 149 members and 563 subscribers. During the year 1,164 cases of disease, many of them being of extreme rarity, were shown at the clinics. The four sessions of practical classes were attended by 198 practitioners. In the laboratory 512 clinical investigations were carried out. The chairman, in proposing the adoption of the report, said that it clearly showed that there was plenty of energy in the college and that excellent work had been done, but they wanted more members and subscribers. Fleet-Surgeon A. W. French proposed, and Dr. J. Fletcher Little seconded, a vote of thanks to five retiring members of the council, which was carried, and they were re-elected, together with Dr. F. M. Sandwith. The chairman and the medical superintendent were thanked for their active interest in the work of the college.

Inquests.

At Greenwich, on March 22nd, Mr. H. R. Oswald held an inquest on the body of Dr. Henry William Payne Makeham, aged 54 years, of 330, New Cross Road. Mrs. Makeham, the widow, stated that her husband had recently suffered from erysipelas, but had nearly recovered. On Tuesday evening she returned home and found him very drowsy. As she knew that he had been in the habit of taking morphia to relieve abdominal pains, she asked him if he had taken morphia, but he appeared too insensible to answer her. Later she found in a pocket of the coat he was wearing a paper which she suspected had contained morphia. He was not depressed, and had never threatened to take his life. Dr. Kenneth Brewer having stated that the cause of death, which took place on Wednesday morning, was asphyxia following morphine-poisoning, the jury returned a verdict of "Death by misadventure."

The Sale of Poisons.

Mrs. Simpson, a widow, carrying on business as a chemist at Hoxton, was summoned at Old Street, London, under the 17th section of the Pharmaceutical Act for selling a scheduled poison in a bottle not

(*a*) "Helonan: An Egyptian Health Resort, and How to Reach It." By H. Overton Hobson, M.D. Pp. 88, with 35 illustrations and 2 Maps. London: Longmans, Green and Co. 1906. Price 2s. 6d. net.

(*b*) "The Climate of Lisbon and of the Two Health Resorts in its Immediate Neighbourhood, Mont' Estoril, on the Riviera of Portugal and Ciutra." By Dr. D. G. Dalgado. Pp. 52. London: H. K. Lewis. 1906. Price 2s. 6d.

(*a*) "The Illustrated Medical Dictionary." A new and complete dictionary of the terms used in Medicine, Surgery, Dentistry, Pharmacy, Chemistry, and the Kindred Branches, with their pronunciation, derivation, and definition. By W. A. Newman Dorland, A.M., M.D., Assistant Obstetrician to the University of Pennsylvania Hospital, &c., &c. Fourth edition, revised and enlarged. London: Saunders and Co. 1906. Pp. 836.

labelled with her name and address as seller. The opening statement showed that the child of people named Wheatley had died from drinking carbolic acid, counsel saying that the child was only two and a half years old, and yet had taken up a bottle from the table and drank from it. Mr. Cluer (astonished): At that age? The bottle was produced, and proved to be a pint black bottle bearing the label of a well-known firm of brewers. On one side, but not across the label, the bottle bore a narrow label in red letters with the word "Poison." The prosecution added that the Act required that the name and address of the seller should be added. For the defence, Mr. Margetts said that Mrs. Simpson had been carrying on the business since the death of her husband, and had served the man Wheatley with the disinfectant in question on a statement by him that a child of his had been removed suffering from fever. She had acted from oversight, and had taken the unfortunate result very much to heart. Mr. Cluer: The best defence is that, however the bottle might have been labelled, it would not have prevented a baby of two and a half years from drinking from it. Mrs. Simpson need not allow the death of this child to worry her mind. It was no act of carelessness on her part which had contributed to it. For the breach of the Act he fined her 20s. and 2s. costs.

Infant Mortality at Barrhead.

SOME time ago the Town Council of Barrhead appointed a nurse to give her services in cases of birth in the poorer classes of the community, the object being to reduce the death-rate among infants, which is abnormally high in the borough. Recently it became apparent that the relations between the nurse and the local medical men were not of the most harmonious character, and a special meeting of the Town Council was called for the consideration of the matter. The meeting was held in private, but a minute has now been issued from which it appears that the points of difference were fully discussed, it being agreed, the doctors present cordially concurring, "that the nurse should continue her work on existing lines, and that the doctors would support and utilise the services of the nurse in attaining the objects aimed at."

Medical Education of Women.

THE Scottish Association for the Medical Education of Women held their annual meeting in the College, Chambers Street, Edinburgh, yesterday afternoon. Sir Alexander Christison, Bart., who presided, said the College had been very prosperous. It had started on a small scale, but was now flourishing. Miss Fairgeld, in submitting a motion "that every effort be made to obtain entrance to the University for first-year medical subjects," said that her reason was that they knew the matter had been brought up by other channels to the notice of the University Court. The matter had been treated from the standpoint of scientific students. They must regard the classes as not being purely medical classes at all but as science classes, and as such there were some prospects that they might be excluded altogether from the medical curriculum. Miss Lowe moved the previous question. She maintained it was by far too great a question to decide in an afternoon. It touched upon a big area of University reform. If the women went to University classes, the school would be affected to a great extent. Dr. A. Goodall seconded, and after discussion the motion was withdrawn for the present.

Flowers as Ozone Producers.

THE medical officer of health to the Tunbridge Wells Corporation reports, for the past year, the lowest death rate on record, viz., 11.35 per 1,000 of the inhabitants. The Town Council makes a novel recommendation to householders to ensure even healthier surroundings. It urges that, instead of keeping fowls and domestic animals in small gardens, sweet smelling flowers, such as mignonette, lavender, and mint should be planted, as these produce ozone in large quantities, and are most useful in purifying and disinfecting the air.

The Spread of Anthrax.

A QUESTION was asked in the House of Commons a few days ago of the President of the Board of Agriculture whether he was aware there were twenty-eight outbreaks of anthrax and thirty-six animals attacked by the disease in seventeen different counties in England, Wales and Scotland in a week; and whether in consequence of the spread of anthrax throughout the country, which is not only financially disastrous but dangerous to human beings who have to deal with it, the Board of Agriculture would institute an inquiry as to the origin of the disease and as to what steps should be taken to stamp it out. In reply thereto Sir E. Strachey regretted that the reported increase was but too true, and that the first part of his hon. friend's question was in the affirmative, but was happy to say that the disease is not increasing throughout the country, the number of cases this year being slightly less. Investigations are proceeding both as regards the nature of the disease and the means by which it is spread, and any amendments in the existing order on the subject which may appear to be necessary will at once be made.

Sale of a Celebrated Medical Residence.

THE sale of 123 Harley Street, Cavendish Square, which has been in the occupation of well-known medical men for nearly a century, is announced for sale by auction on the 12th inst. Competition for houses by medical men in this centre of activity is at all times keen, and doubtless the present occasion will prove no exception.

British Medical Association Meeting at Exeter.

IT is proposed on the occasion of the visit of the British Medical Association to Exeter this year to amplify, if possible, the handbook of the locality issued to members attending the meeting into a handsome volume, with special articles, historical, descriptive climatological, etc., profusely illustrated with photographs of Devon and Cornwall scenery, and portraits of worthies of the two counties, so that instead of finding its way into the waste-paper basket this book shall be given a permanent place on the bookshelf or table as a necessary work of reference. If this can be accomplished, the claims of the health resorts and residential neighbourhoods of Devon and Cornwall will be placed permanently before the medical profession. About 1,000 medical men from all parts of the kingdom, including many of the leading authorities on medicine and surgery, and possibly not a few from the Colonies and foreign countries, are expected to attend the meeting. Further, it is intended, if sufficient money can be raised to carry out this scheme, that many extra copies shall be taken over by the United Devon Association for distribution in this country and abroad. This book of the south-west will be compiled and published by the South-Western Branch of the British Medical Association, and a copy will be presented to each member attending the annual meeting of the British Medical Association.

Trinity College, Dublin—Hilary, 1907.

Licence in Dental Science.—Charles E. Moore.

Intermediate Medical Examination (Part II.).—Thomas A. Hughes and Adams A. M'Connell, passed on High Marks; Robert E. T. Tatlow, George E. Craig, William R. Watson, Albert E. Wynne, Ralph T. St. J. Brooks, Eric J. Powell, Charles G. S. Baronsfeather, Desmond Drew, Victor B. Kyle, Wellesley R. Allen, Charles B. Jones, James D. Murphy.

Final Medical Examination (Part II.).—*Midwifery:* Julian B. Jones, passed on High Marks; Duncan F. Hunter, Charles H. O'Rorke, Oliver St. J. Gogarty, Edmund H. Sheehan, Bethel A. H. Solomons, George H. Stack, Allman J. Powell, James D. K. Roche, James G. M. Moloney, Thomas P. S. Eves.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT SURGICAL LITERATURE.

The Radical Cure of Trigeminal Neuralgia by Means of Peripheral Operations.—Moschcowitz (*Med. Record*, February 16th, 1907) states that all recurrences in trigeminal neuralgia have been found to be due to regeneration and re-union of the divided nerve tissue. The desideratum at present, therefore, is to prevent this occurring. Most of the terminal endings of the trigeminal nerve make their exit from the skull through bony foramina. This suggests the possibility of dividing the nerve in the canal, and preventing the re-union by permanently plugging up the foramen of exit. The author accomplished this by means of silver buttons, each consisting of a flat top not more than one-sixty-fourth of an inch in thickness, and of a diameter of about one-quarter of an inch. It is sufficiently firm to retain its shape, and yet sufficiently malleable, so that it will give if lightly hammered on. In the centre there is annealed a silver rivet, ranging in thickness from one thirty-second of an inch to one-eight of an inch, and about three-eights of an inch in length. The operation in appropriate cases consists in the following steps:—Through an incision of suitable length, half to one inch, the foramen in question is exposed. The nerve is then carefully isolated from accompanying vessels; a short length is drawn out from the foramen, in order to secure that the nerve will detract sufficiently from the surface, and it is divided. The accompanying vessels are treated in a similar manner after double ligature. A button of suitable diameter is selected and driven into the foramen, so as to fill it completely. As some foramen are not absolutely round, the overhanging flat top is now moulded to the underlying cone, so as to make the closure absolutely tight. The small cutaneous skin incision is closed. If necessary the entire operation can be done in local anæsthesia. The author records some cases. Case I. Lady, æt. 58, had suffered for several years from left-sided trigeminal neuralgia involving the three divisions of the nerve. Local and internal treatment, and removal of teeth had not improved the condition. The pain was very frequent and severe. The patient was operated upon the 17th September. The mental infraorbital and supraorbital foramina were exposed in the order named by small transverse incisions; the nerves divided and the foramina plugged by means of silver buttons, the pain completely disappeared, and has not returned since. The buried metal causes no discomfort whatever. The other cases recorded were of a similar nature. S.

A Report on Clinical Experiences with Spinal Analgesia.—Barker (*Brit. Med. Journ.*, March 23rd, 1907) reports a series of one hundred cases in which the procedure was employed tentatively during the last year in the ordinary course of hospital study. In all the cases stovaine only has been employed in order to gain some adequate idea of its behaviour from a fair number of observations. The patients' ages varied from fifteen to seventy-one years. The amount of stovaine injected was from three to six centigrammes, in most cases about five. In only three, among the first fifty cases was two centigrammes extra required to produce the desired affect. The duration of analgesia varied between twenty-three minutes and a couple of hours. Adrenalin compounds were added in these cases. Adrenalin derivatives undoubtedly prolong the analgesia, but the author cannot help thinking that some of the few undesirable sequelæ recorded have been due to them. Among the operations performed during spinal analgesia are—strangulated hernia, resection of gut, appendictomy, piles, wiring patella, amputation through the thigh, &c. The author has performed no operation above the umbilicus yet. In from five to ten minutes after the injection the patient was not only completely anæsthetised, but also relaxed in all the parts supplied below the parts reached to. In rectal operations—piles, for instance—the sphincters relaxed completely, and the piles presented themselves without any dilatation with the fingers, and with the straining and movement sometimes seen under general anæsthesia. That the specific influence of stovaine is limited almost exclusively to the locality into which it is injected in moderate doses seems highly probable from experience of it as a local and spinal anæsthetic. Its effect, if any, on the pulse is to reduce its frequency, and increase its volume, and a patient after injection usually feels and looks warmer than before. The injection can be made in the second or third interspace of the lumbar vertabræ, thus avoiding the cord. Puncture in the middle line is easiest, safest, and best. Here the puncture is least painful, and there is less danger of wounding any nerve structures, as on either side there is a possibility of touching the spands of the cauda equina. The puncture is easiest with the patient sitting on the edge of a table with his back rounded to its maximum. The author employs a modification of Bier's needle. The needle pierces the dura mater, and a cannula through which the fluid is injected projects just beyond this into the subdural space. S.

A Case of Gastro-Enterostomy Combined with Gastrostomy, for Ulceration of the Stomach.—Moynihan (*Brit. Med. Journ.*, March 23rd, 1907) reports his treatment of a patient who accidentally swallowed a few mouthfuls of hydrochloric acid, which caused extensive ulceration of the stomach with consequent stenosis of the pylorus. There was no obstruction of the œsophagus. A few days after the accident the lips, mouth and throat became very sore, and any food was followed by severe pain and vomiting. Seven weeks after accident the abdomen was opened. The stomach was small. The pyloric antrum was solid and hard, and it seemed quite impossible that any fluid could find its way through so dense a tumour. Posterior gastro-enterostomy was performed. The gastric mucosa was a deep plum colour and very attenuated. When the stomach was replaced a small opening was made on its anterior surface, through which an indiarubber drainage tube was passed. With the fingers of the right hand placed below the stomach this tube was guided through the gastro-enterostomy opening into the distal limb of the tube for about five inches. This being done, the right hand was removed, and the omentum replaced. At the point of entrance of the tube into the stomach on its anterior wall a gastrostomy was now performed after "Senn method." A single cat-gut stitch fixed the tube to the end of the opening, and a series of circular purse string sutures were applied round the tube in tiers, so that a cone of stomach was enfolded. A couple of sutures then fixed the anterior wall of the stomach to the panital peritoneum of the anterior abdominal wall, and the wound was closed. For the first two and a half weeks the patient was fed every four hours directly into the jejunum. On the eighteenth day food was again given by the mouth. The tube was removed in the fourth week, and the little wound left in the abdominal wall speedily granulated up; there was never any leakage from it. The operation practiced in this case effects two purposes: it enables the patient to be fed while healing of the ulcerated surfaces is in progress, and by means of the gastro-enterostomy it establishes an alternate route from the stomach when the pylorus is closed by the contractions of the cicatricial tissue deposited in the ulcers. S.

Chorioidal Hæmorrhage after Cataract Extraction.—McNabb (*Ophthal. Review*, November, 1906) records a case of this unusual complication. In the records of the Manchester Eye Hospital for the past twenty years he finds mention of two other cases out of a total of 4,422 extractions. From the cases reported in literature we learn that the hæmorrhage may occur immediately after the corneal section, later before the completion of the operation, or still later, some few hours or a day after the operation. In the case under notice NcNabb attempted a confined operation, but fluid vitreous escaped after the iridectomy and the lens had to be spooned out. About two hours afterwards the dressings became soaked with blood. The eye was removed two weeks later. McNabb had removed a cataract from the other eye with excellent result. A pathological examination showed the vessels to be undergoing slight fatty degeneration. No amyloid degeneration could be found. McNabb says that the most frequent cause of these hæmorrhages is probably atheromatous or fatty degeneration of the vessels which give on the sudden reduction of tension following the incision in the cornea. In cases of increased tension, in the decrepit, or when marked general vascular changes are evident the author advises a preliminary iridectomy to be performed.

M.

Extraction of the Lens in High Myopia.—De Font Reaulx (*Annals d'Oculistique*, Feb., 1906) after following cases for five years or more declares himself rather in favour of this procedure, although he thinks there is no operation in ophthalmic surgery where the surgeon's responsibilities are so great or in which one is confronted with so many risks and pit falls. All this is due to the remote disappointing results which are met with from time to time, the repeated operations which are necessary, and the long time that the patient must give to the course of treatment. He warns us not to be carried away by the gratifying and immediate results that operation has on distant vision, but to remember that in a very large proportion of cases the patient comes complaining of this near vision. Unless we select those cases which will leave the eye myopic after the lens has been removed we will be disappointed to find the patient using the unoperated eye for near work. Before operation the patient's position, occupation etc., should be carefully considered and weighed with, the optical results expected to be obtained. M.

Exophthalmic Goitre.—P. Horowitz (*Post-Graduate*, March, 1907) thinks it is most probable that exophthalmic goitre is caused by some form of toxæmia, it is a disease, however, in which we have no definite predisposing cause. The pathological findings in the gland are those which may occur in a simple parenchymatous goitre, and in the so-called cases of primary exophthalmic goitre, a hypertrophy of the epithelial cell, but no apparent increase of the secretion, or of the colloid material. In the rest of the body there is practically no change, except for an enlargement of the thymus gland occasionally, and possibly some fatty degeneration of the muscles. The disease is more frequent in women than in men. There may be acute exacerbations with symptoms simulating acute septic poisoning or malignant endocarditis. The diagnosis can as a rule be made from the general symptom complex, the exophthalmus, and the enlarged gland, but we must not forget that there are cases that do not have either the exophthalmus or the enlarged gland, but which may develop later. The prognosis in acute cases is not good, but chronic cases go on and may recover with a fair amount of health, and retain it for a long period. The different therapeutic agents advanced for the relief and cure do not always accomplish the same results in different cases, probably the Roger-Beebe serum, and the surgical treatment may take the place of the numerous other forms of treating the disease, which have been advocated, so far, however, not enough results have been obtained to warrant our recommending one mode of treatment as being better than another. G.

Pyrexia in Hodgkin's Disease.—F. Taylor reports (*Med. Review*, March, 1907) two cases of chronic relapsing pyrexia associated with Hodgkin's disease. Although it has been known for a long time that pyrexial attacks separated by long periods of apyrexia are not uncommon in the course of this disease, yet the profession is not familiar with this relapsing fever much less with its extraordinary duration. The writer then describes fully two such cases, and mentions seven others. From these nine he draws the following conclusions:—(1) In Hodgkin's disease a varying temperature is common; (2) in some cases there are relapses with periods of apyrexia; (3) the temperature may be continuously high for long periods, the periods of high fever may alternate with periods of lower fever; (4) the relapsing pyrexia may be of assistance in diagnosing doubtful cases of Hodgkin's disease. G.

The Early Diagnosis of Cancer of the Rectum.—D. Drew calls attention (*Clinical Journal*, Dec., 1906) to the description usually given in the text books of cancer of the rectum, as an irregular nodular mass narrowing the lumen of the bowel, with a surface which is often ulcerated and bleeds on examination. If these signs are relied on for making the diagnosis, it is no wonder that the results of operation for cancer of the rectum are disappointing, for these signs will only occur late in the course of this disease. Here as in most other localities, cancer is at the start quite painless, and for a long time the only sensation the patient may feel is one as if the bowel had not been completely emptied after defæcation has taken place. Later on piles may make their appearance. The importance of a thorough examination of the rectum in all such cases cannot be over-estimated. In the large majority of cases cancer of the rectum commences within easy reach of the finger, and the finger is the best instrument to examine the bowel with. If any small ulcer or hard nodule is felt, a very complete examination of the lower bowel should at once be made, if necessary, under an anæsthetic; this is not as a rule necessary unless the growth is very high up in the rectum. If nothing definite can be felt by the examining finger, and symptoms continue of some irritation in the bowel, then a proctoscope should be used and the upper part of the rectum examined in this way. The chances of success after removal of such a growth are enormously increased if the diagnosis is made early. G.

Jaundice.—A. Pisani (*Post-Graduate*) March, 1907, in a paper dealing with numerous cases of jaundice, their clinical symptoms, and the pathology of the affection, believes that the natural deductions to be drawn from this disease are:—(1) That all forms of jaundice are either intra-lobular, or extra hepatic; (2) that all forms of jaundice are due to obstruction of the biliary passages; (3) that the severity of the jaundice in the inter and intra-lobular forms varies, all depending on the amount of biliary radicles occluded; (4) that the differential diagnosis between the intra-lobular and the inter-lobular forms of jaundice is generally reached after considering the history of the case, and the result obtained in the treatment of the same; (5) that in the extra-hepatic form of jaundice where the obstruction is due to biliary calculi, it is always advisable to submit the patient to a thorough medical treatment before advising him to submit to operative interference; (6) if the obstruction does not yield promptly to medical treatment, surgical interference should at once be instituted. G.

NOTICES TO CORRESPONDENTS, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

M. A. B. (Liverpool).—The society referred to is called the "Association Medicale Internationale pour aider la suppression de la guerre." The president is Dr. Riviere, 25, Rue des Mathurins, Paris, to whom you should apply for the desired information.

Dr. S. M. T.—The powers can be obtained by adopting the Defectives and Epileptics Act, 1899, which is an optional measure, and allows (inter alia) for the provision of special schools, classes, etc., for defective children. Write to the Secretary, Board of Education, Whitehall, S.W.

R. S. Foster.—The summer opening of the medical schools varies somewhat, but the majority recommence on the 22nd inst. You will see the date of many announced in our advertisement columns.

One Interested.—Thanks for the compliment, but the communication is scarcely suitable for our columns.

"PARTING IS SUCH SWEET SORROW."

The women part with ovaries,
The men with prostate gland;
But why relinquish any more
They fail to understand.

The list of human giblets now
Is mounting up each year—
Tonsils, appendix, thyroid glands,
Are given without a tear.

But when at length you've nearly lost
The most of your inside,
You very naturally conclude
'Twas time you should have died.

A. D.

Historicus.—(1) It is a mistake to think that Keats was an inefficient student of medicine, even if he did not care for its study. Although he broke his articles with Dr. Hammond, of Edmonton, to whom he was apprenticed, it was by mutual consent, and during his career at Guy's he was diligent, as his notebooks sufficiently testify. Indeed, he seems to have been genuinely attached to Sir Astley Cooper, who was then at his zenith. (2) He did perform one, but only one, operation—viz., opening the temporal artery. V. Letters. (3) He qualified L.S.A. on July 26th, 1816, but never practised.

Meetings of the Societies, Lectures, &c.

Wednesday, April 3rd.

Obstetrical Society of London (20, Hanover Square, W.).—8 p.m.: Special General Meeting to receive the Report of the Council. Specimens will be shown by Dr. H. R. Andrews, Dr. Lewers, and Mr. J. H. Dauber. Paper:—Mr. J. D. Malcolm: On the Advisability of Removing the Cervix in Performing Hysterectomy.

North-East London Post-Graduate College (Tottenham Hospital, N.).—Cliniques:—2.30 p.m.: Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Out-Patient (Dr. Whipham).

Central London Throat and Ear Hospital (Gray's Inn Road, W.C.).—5 p.m.: Demonstration:—Mr. Stuart-Low: Middle Ear and Labyrinth.

Thursday, April 4th.

North-East London Clinical Society (Tottenham Hospital, N.).—4 p.m.: Clinical Cases.

North-East London Post-Graduate College (Tottenham Hospital, N.).—2.30 p.m.: Demonstration on Fevers (Dr. F. Thomson at the North-Eastern Fever Hospital, St. Ann's Road, N.), Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-Patient (Dr. Whiting), Surgical Out-Patient (Mr. Carson). 3 p.m.: Medical In-Patient (Dr. Chappel).

Friday, April 5th.

West London Medico-Chirurgical Society.—8 p.m.: Clinical Evening.

Laryngological Society of London (20, Hanover Square, W.).—5 p.m.—Exhibition of Cases and Specimens.

West Kent Medico-Chirurgical Society.—Discussion on the Necessity for Organisation in the Medical Profession (opened by Dr. F. S. Toogood).

North-East London Post-Graduate College (Tottenham Hospital, N.).—9.30 a.m.. Clinique:—Surgical Out-Patient (Mr. H. Evans). 2,30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-Patient (Dr. Auld), Eye (Mr. Brooks). 3 p.m.: Medical In-Patient (Dr. Leslie).

Vacancies.

Royal Devon and Exeter Hospital.—House Surgeon. Salary £120 per annum, with board, apartments, and washing. Applications to Samuel S. Cole, Acting Secretary.

Wolverhampton and Staffordshire General Hospital.—Senior House Surgeon. Salary £100 per annum, with board, lodging, and laundry. Applications to J. Stephen Neil, House Governor and Secretary, Wolverhampton.

Parish of Birmingham Workhouse Infirmary.—Assistant Resident Surgical Officer. Salary £104 per annum, with furnished apartments, rations, coal, gas, laundry, and attendance. Applications to Charles Fletcher, Clerk to the Guardians, Parish Offices, Edmund Street.

Killarney Union.—Medical Officer. Salary £150 per annum, with £25 per annum as Medical Officer of Health, and heusual Vaccination and Registration Fees. Immediate application to P. Carey, Clerk of Union.

West Sussex County Asylum and Graylingwell Mental Hospital, Chichester.—Junior Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, attendance, etc. Applications to the Medical Superintendent.

Leicestershire and Rutland Asylum, Leicester.—Second Assistant Medical Officer. Salary £130 per annum, with apartments, board, and washing. Applications to W. J. Freer, Esq., New Street, Leicester.

University of Birmingham.—Demonstratorship in Anatomy. Salary £150 per annum. Applications to Geo. H. Morley, Secretary.

Cornwall County Asylum, Bodmin.—Third Assistant Medical Officer. Salary £140 a year, with furnished rooms, rations, laundry, and attendance. Applications to Medical Superintendent.

Bury Infirmary.—A Senior House Surgeon. Salary £110, with board, residence, and attendance. Applications to the Honorary Secretary, Dispensary, Knowsley Street, Bury, Lancashire.

Lancashire County Asylum, Winwick, Warrington.—Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, attendance, and washing. Applications to the Medical Superintendent.

Birkenhead Union.—Resident Assistant Medical Officer. Salary £120 per annum, with board, washing, and apartments. Applications to John Carter, Clerk to the Guardians, Poor-Law Offices, Birkenhead.

Birmingham, the Queen's Hospital.—Second Physician for Out-Patients and Pathologist. Salary £100 per annum. Applications to Arthur Hulme, Secretary.

Appointments.

Cooke, Thomas Alfred Burnard, L.R.C.P. Lond., M.R.C.S., District Medical Officer by the Pembroke Board of Guardians.

Johnson, James Bovell, M.D., C.M. Montreal, L.S.A. Lond., District Medical Officer by the Sturminster (Dorset) Board of Guardians.

King, William Wilfrid, L.R.C.P., M.R.C.S., Resident Obstetric Officer at the Bristol Royal Infirmary.

Smith, Lionel Shingleton, L.R.C.P. Lond., M.R.C.S., House Surgeon at the South Devon and East Cornwall Hospital, Plymouth.

Taylor, Frank E., M.D., B.S. Lond., F.R.C.S. Eng., M.R.C.P. Lond., D.P.H. Cantab., Physician for Diseases of Women to the North-West London Hospital and to the St. Marylebone General Dispensary.

Turner, Arthur John, M.B., B.S. Durh., Junior House Surgeon at the Bristol Royal Infirmary.

Walters, Charles Ferrier, F.R.C.S. Eng., L.R.C.P. Lond., Surgical Registrar to the Bristol Royal Infirmary.

Births.

Horner.—On March 28th, at 77 Church Hill, Walthamstow, the wife of C. J. Horner, M.R.C.S., L.R.C.P., of a daughter.

Hanna.—On March 23rd, at Alma House, Exmouth, the wife of G. H. Hanna, M.B., Ch.B., of a daughter.

Hardenberg.—On March 25th, at Duffield House, Watford, the wife of E. F. H. Hardenberg, M.B., M.R.C.S., L.R.C.P., of a son.

Parker.—On March 23rd, at Clovelly, Kilmacolm, Renfrewshire, the wife of James Parker, M.B., C.M., of a son.

Scott.—On March 25th, at Hampton-in-Arden, the wife of W. Sibbald Scott, M.B., of a daughter.

Underhill.—On March 27th, at San Remo, Herne Hill, London, the wife of Thomas Hill Underhill, M.B., M.Ch., of a daughter.

Marriages.

Campbell—Mactaggart.—On March 21st, at St. Mary's, Thetford, Robert Campbell, F.R.C.S.Eng., of Belfast, to Amy Isabella, daughter of the late William Mactaggart and Mrs. Mactaggart, of Thetford, Norfolk.

Weekes—Murdoch.—On March 30th, at Parish Church, Lenzie, N.B., Charles Peterson Weekes, F.R.C.S.Ed., only son of William Tucker Weekes, of Elmwood, Sutton, Surrey, to Margaret, fourth daughter of William Murdoch, of Leebank, Lenzie, N.B.

Deaths.

Myrtle.—On March 29th, at 10 Park Parade, Harrogate, Andrew Scott Myrtle, M.D., J.P., in his 82nd year.

Waller.—On March 29th, at Peterborough, Edmund Waller, M.D., R.N., in his 75th year.

MOTOR: Electric Krieger Car to be Sold,

A Bargain, to cover advances, suitable for a Medical Gentleman, being easy riding and silent, front wheel driven, two motors, 12 h.p. tonneau, body green, upholstered red morocco, hold 4 or 5 persons, been but little used and in perfect running order; immediate sale required, arrangement for payment can be made by instalments—Apply to "Armitage," 6, Hamilton Street, Strand, London, W.C.

VOL. CXXXIV. WEDNESDAY, APRIL 10, 1907. No. 15

NOTES AND COMMENTS.

Croaking at Epsom.

Epsom seems the withered branch which Lord Rosebery finds the most congenial, or, perhaps we should say, the latest croaking place, for everybody who has a grievance tries to prevail on the ex-Premier to come to his district and do his croaking for him. A little while ago it was the old Brig of Ayr, then came the momentous question of cavalry in Scotland; quite recently his old colleagues were found to be in need of admonishment, and now the issue is the lunatic-containing properties of Epsom. It certainly is a little odd that the London County Council should have pitched on the *locus classicus* of salts and race meetings as a site for two lunatic asylums and an epileptic colony, to say nothing of the third asylum now in contemplation. But after all some spot has to be chosen, and one would think that once the step has been taken, an odd asylum or two would not make much difference. The escaped lunatic danger in these days of good asylum administration is somewhat of a bogie. People's ideas of escaped lunatics are generally derived from novels and sensational train stories which bear a very remote relation to life. The lunatic who escapes is generally a harmless person whose disposition is so benign that he is not watched with the same eagle-eye as his companions; the dangerous cases are not likely to have much chance of regaining their liberty. Still Epsonians may feel an unmerited stigma is being cast on their pretty town, and if the County Council can select some other spot for their purpose it may be as well.

Transfusion and Confusion.

Here it is again! The chronic transfusion canard to wit. Perhaps it would be more accurate to say the recurring canard, for it generally enjoys a latent period of six months before cropping up again. The trouble having died a natural death in England, and having been introduced with wearisome iteration from various continental countries, has at last found a sure and abiding resting-place in America, whence we see it pays biennial visits to this country. This time it comes from Philadelphia and *dramatis personæ* are a husband and wife. The latter has been slowly dying of anæmia, and after despairing efforts of the doctors to wrestle with the insidious malady, as a last resource transfusion of human blood was decided on. Enter the husband. His arm is bared and the physician "pumps" blood from his veins to his wife's. The wife rapidly recovers, and the husband after lying at death's door for a suitable period, does likewise. Altogether a very pretty situation and one capable of giving points to the old one of sucking the tracheotomy tube. It is touching to note that though a good operation for appendicitis nowadays can barely stir the pulse, the public will not consent to part from its old and tried horrors, among which the transfusion business is one of the most cherished.

Wimborne Fight.

We are sorry to read that through the action of Dr. F. T. Charlton, of Blandford, the fight for an increased salary for the medical officer of the Wimborne Workhouse has been rendered nugatory. The gentleman named is reported to have accepted the post when his colleagues were standing out together for what was considered a proper salary for the appointment. The medical men of the district have written a letter saying that they refuse absolutely to recognise Dr. Charlton professionally, and that they will not aid him in any way in his practice in connection with the guardian's work. This is the natural and logical outcome of the step taken by Dr. Charlton, and it is a thousand pities that it should have been evoked.

Vaccination "At Home."

The recent scare of "black" smallpox in France caused a very wide recourse to vaccination, all classes of society flocking to their medical advisers for the protective operation. The French, whatever their failings may be, are a logical people, and they understand that when recently-vaccinated people do not catch smallpox and unvaccinated ones do, there is some efficacy in the process—an inference which our fellow-countrymen are in many instances less apt to draw. But lest they should be suspected of taking their pleasures gloomily the inhabitants of Paris made their vaccinations the occasion of a little social enjoyment, and from the groups who were inoculated direct from the calf in the courtyard to the grand dames in the salons, merriment and chaff prevailed. Indeed one leader of society made the scare a source of new form of social entertainment, and to the joy of her friends gave an "At Home," the cards for which bore "Vaccination" as the attraction in the corner. On assembling, the party were regaled with a lecture by a fluent young doctor who illustrated his remarks with photographs and pictures of smallpox and vaccine-vesicles, and when refreshments were served, the lancet and lymph were produced, and inoculations became the order of the day. Sympathetic eyes were directed to the wounds inflicted on each patient and after the operation restoratives were administered in the shape of ices and champagne. Vaccination would seem to rank with one of the (few) things that they do better in France.

The Recreation of a Novelist.

Mrs. Stannard ("John Strange Winter") is well known as a writer of bland and easily-digested, if not over-nutritious, fiction. She is also, like some other equally great and famous writers, a manufacturer of, and trader in, toilet preparations. Somebody has been so wicked as to suggest, however, that Mrs. Stannard does not herself control the business, but that she merely sells her valuable name to some chemist, and she writes, therefore, a letter to our contemporary, the *Chemist and Druggist*, asking angrily, "Are Chemist's Prejudiced ?" (*sic.*) In this letter she justifies the choice of her hobby, in that she finds it "delicious and revitalising," "to turn from particularly ageing labour to a quiet laboratory." Moreover, "if you have brains enough to write novels, you gain more practical knowledge than any professional training will bring you." This is a delightfully simple doctrine. The person with "brains enough to write novels" is qualified to adopt any professional career he or she chooses, and, as Mrs. Stannard elegantly puts it, "to get there." We stand amazed at the lady's moderation! Why did she choose the quiet laboratory, when she might have been, let us say, a consulting surgeon, or a leader of the bar, or Archbishop of Canterbury ? We wonder if other people "with brains enough to write novels," know all that is open to them ? Mr. Bernard Shaw, who once wrote a novel, might be President of the College of Surgeons; Mr. George Moore would make an edifying Bishop; Mr. Hall Caine would doubtless be Prime Minister, unless indeed, Miss Corelli "got there" first; but Mrs. Stannard and Mr. Sims would still be selling their hair-washes. By the way, Mrs. Stannard does not lack business ability, as she does not miss the opportunity of her letter of referring incidentally to her successful treatment of a lady "after ten years of suffering and constant medical treatment."

LEADING ARTICLE.

THE USE OF ALCOHOL.

For a considerable number of years the medical world may be said to have made its mind up on the use and value of alcohol to mankind. Needless to say, there are two important and entirely distinct issues involved in the primary discussion of alcohol according to its medicinal and its dietetic administration. So far as its therapeutic properties are concerned few experienced medical men would care to eliminate alcohol from their armamentarium when called upon to deal with acute conditions, such as heart failure, shock, and various rapidly progressive infections. In the treatment of many tropical maladies to deprive the physician of alcohol would be to take away a valuable adjunct. In our own temperate climes, again, the value of alcohol in dealing with the progressive infection and results of a debilitating disease, such as osteitis deformans, is too well established to need more than a passing reference. For all that, there can be little doubt that patients suffering from many severe diseases recover just as well without as with the aid of alcohol. That fact was shown years ago in the case of pneumonia, an affection in which large quantities of spirits were regarded as absolutely essential. The demonstration that the percentage of deaths was not increased by withholding whiskey and brandy came like a revelation to a former generation. Since that time the pendulum has swung always in the direction of increasing moderation. Pushed to an extreme in the case of the London Temperance Hospital the treatment of all medical and surgical conditions is undertaken practically without the prescribing of alcohol. As a general statement of ordinary medical practice it might fairly be said that while for the most part alcohol is unnecessary in the treatment of disease, on the other hand it is most valuable and, indeed, indispensable in certain emergencies, and in some acute, as well as in some debilitating chronic maladies, it is often most beneficial. Lastly, its moderate use by a multitude of patients is followed by no harmful results. That, or something like that, would describe the attitude of the average medical practitioner, who is not a fanatic one way or the other as regards alcohol. The medical point of view has been dealt with at some length, because it so nearly coincides with that of the average layman. Alcohol is not a necessity for any human being; some people may consume it in moderate doses and suffer neither mental, moral nor bodily harm during a long lifetime; others, however, are so constituted that alcohol to them spells disaster to mind and body. On the whole the cause of temperance is that of progress in thrift; comfort, morality, physique, education, in a word, of all that is of chief import to the nation in its slow and painful struggle to reach the ideals of social evolution. During the past century a vast change has come over the drinking habits of our country, but a great deal remains to be done before we can rid ourselves of one of the most potent sources of disease, misery, crime and insanity at work in our midst. Under these circumstances the recent announcement in a medical contemporary by a small knot of eminent medical men of their general approval of the use of alcoholic beverages came somewhat as a surprise to the general community. It has raised a hurricane of more or less heated discussion in the lay newspapers, a fact that may be interpreted as a gratifying proof of the wholesome temperance leaven that has permeated modern society. The interesting point in connection with the manifesto is its apparent spontaneity. Why we wonder should these gentlemen suddenly have been moved to protest against the general feeling with regard to the use of alcohol that is growing up in the profession? No one denies the weight that such a protest receives from the status of the physicians and surgeons who signed it, but were these gentlemen suddenly and at the same moment moved by a spirit of indignation against immoderate temperance? Or did some artful agent "nobble" them? The manifesto contains no explanation of its *raison d'etre*, it springs on to the stage from some unexpected trap-door and disappears in a cloud of great names. In a word, did the signatories know what they were signing, or for what purpose they were signing it, or what use was going to be made of their names? We cannot forget that the Government have announced their intention of introducing a new Licensing Bill soon after Easter, and that the brewers believe, and tremble.

THE FRAUDULENT DRUG TRADE.

A letter from a leading practical chemist appears to-day in our correspondence columns under the signature of "Analyst." Unfortunately in dealing with numerous communications of the kind that reach our office we are, for various reasons, unable to publish much information that would be useful to the general public. The writers ask indignantly whether nothing can be done to put a stop to such practices, and whether The Medical Press will not expose the individuals guilty of such deception. The case exposed by "Analyst" is that of a drug widely advertised and sold as a disinfectant of the utmost value and efficiency, whereas it is in reality practically worthless as an antiseptic. Its virtues are lauded to the skies with the exuberant art invariably at the command of the quack advertiser, and a bogus chemical test is suggested to prove to a technically ignorant public the value of the bogus disinfectant. Much as we should wish to expose and punish this particular form of trickery we nevertheless feel that the task is too great for any journal to undertake single-handed. However sustained, fearless and overwhelming our attack on quacks and quackery, general and particular, may be, we nevertheless find ourselves crying in the wilderness to a congregation of medical men, while the great outer world hears nothing of our gospel. The reason is simple, namely, that the lay newspapers dare not hint at the evil by quoting the criticisms of a medical contemporary. As everyone knows, the whole newspaper press, including the "religious" journals, draws a large percentage of its profits from quack advertisements.

It is certain many of the proprietors of these papers are not aware of the nature of the traffic they are abetting; but they are certainly to blame for not enquiring into it. With some of the proprietors it is eminently a case of *noblesse oblige*. The *Morning Post*, the *Daily Telegraph*, the *Daily Mail* are all owned by peers of the realm. These noblemen have all gained their wealth and their positions by means of their papers. Up to lately, the *Times* stood alone in refusing admission to certain classes of quack advertisements; it has lately taken to publication of puffs of even a lower type. The result of this degradation of the leading journal has been the still greater demoralisation of inferior papers. These now all print in form of editorial matter any misleading puff that the advertiser is willing to pay for. No medical paper is in a position to enter upon a campaign of exposure that could only be carried out by constant appeals to the Law Courts. The needed exposure, as we are constantly urging, can only be effectually made by means of a Royal Commission. The story that could be unfolded would touch the consciences of the educated public and of politicians and statesmen and would bring shame upon newspaper proprietors. It would be shown that the fraudulent drug concoction might easily be made amenable for obtaining money under false pretences; and it can hardly be doubted that the necessary new legislation would be without delay constructed. The movement towards promotion of a Royal Commission to enquire into the whole question of medical law, including the subordinate and inseparable question of traffic in fraudulent drugs and nostrums, could be helped on by the chemists if not by their representative corporations such as the Pharmaceutical Society. We commend this suggestion of our correspondent to members of the profession who have addressed us on the subject about which he writes so forcibly to-day.

CURRENT TOPICS.

Lord Lister's Birthday Celebration.

The eightieth birthday of Lord Lister, on April 5th, was marked by many telegrams, addresses, messages of congratulation, and presentations from all parts of the world. The day was spent at his residence in receiving and acknowledging these various tokens of admiration and respect. and a few colleagues presented his lordship with a letter formally recording the decision to signalize the anniversary by republishing all his works. Mr. Jonathan Hutchinson, Sen., headed a deputation from the Royal College of Surgeons, Professor Tilanus, of Amsterdam, presented an address from the physicians and surgeons of that city, and another, presented by Dr. Thorvald Madsen, of Copenhagen, bore the signatures of 1,000 medical men. Lord Lister made a brief reply to these congratulations and presentations. In order to commemorate Lord Lister's thirty years' connection with King's College Hospital, London, a congratulatory address was presented by the members of the medical society and students of the hospital. In view of his early connection with the City as a professor and as a surgeon in the Royal Infirmary, the

Senate of Glasgow University sent an address which recalls that Lord Lister began his great work in Glasgow, and congratulates him upon the many honours which have been deservedly conferred upon him. The Lord Provost of Edinburgh sent a telegram on behalf of the citizens of Edinburgh.

The Growth of Insanity.

The discussion that has been carried on for many months in the correspondence columns of the *Times* on the "Growth of Insanity," shows signs of coming to an end. Judging from the length and vigour of the letters, there is still abundance of material for argument and illustration at the command of the contributors. In what appears to be a parting shot, the "Original Correspondent" remarks that the dispute whether the increase of insanity is "real" or "apparent" seems to him to be relatively trivial, and he is quite willing to abandon the word "increase" and substitute "prevalence." In this view he will find many medical men ready to support him, for it is, of course, a commonplace among the profession that the official returns of insanity are open to serious fallacies. Far more to the point is the question of what real scientific progress has been made in the pathology or prevention of insanity. Apart from Dr. Ford Robertson's recent researches into the microbial causation of general paralysis, "Original Correspondent" asks what is known about the real pathology of insanity that was not known fifty years ago. We agree with his general contention that "identification" and "description" of morbid conditions do not necessarily prove of any practical use to the physician. On the other hand, it would be idle to deny their potential value as stepping-stones to higher things. What is true of insanity to-day has been always more or less true of disease generally. Nevertheless, every now and then, out of the apparently hopeless chaos of pathology emerges the generalisation of a great truth that lays the foundation, or part of the foundation, of future prevention or cure. In so obscure and difficult a subject as insanity, we may yet have to wander in the wilderness for many years—or we may not.

The Coventry Dispute.

The present position at Coventry is worthy of the close attention of the medical profession throughout the Kingdom. As a protest against the terms imposed by the local Provident Dispensary, five out of the seven medical officers have sent in their resignations. The facts of the case have been made widely known, both in the medical and the lay press. If there be any instance in which it would be undesirable for medical men to apply for the vacant posts and thereby handicap the action of their brother practitioners, who are making so supreme a sacrifice on the altar of principle, such a necessity is to be found this day at Coventry. In spite of the wide publication of the circumstances attending the resignations, it is understood that there are several applicants in the field. If that report be true, it points to a lack of honourable feeling in the profession that is most deplorable. The unwisdom of such conduct, again, is conspicuous, as it is only by unity of action that medical practitioners can ever hope to secure a more adequate general standard of emolument for their services. The future career of any who accept the Coventry posts will be anything but enviable, for they must be regarded with contempt by all fair-minded and honourable medical men.

Medical Alliance Meeting.

The representatives of the Friendly Societies' Medical Associations assembled last week at Exeter for their twenty-seventh annual conference, and after being welcomed by the Mayor, they proceeded to take counsel together. The President, in his opening address, referred to the growth of the Alliance, showing that whereas when they met together at Exeter twenty-five years previously there were delegates from only nine associations, at that conference three hundred thousand members and seventy towns were represented. After eulogising the Alliance as "the best system ever adopted to help themselves," he proceeded to deal with the differences between them and the medical profession. These differences are sufficiently well known, and it would serve no good purpose to conceal the fact that medical men regard the Alliance as very far from being the best system conceivable. Any system of medical aid which is not based on sound principles of remuneration is of the nature of charity, and as such must be treated on different lines from a purely business undertaking. Self-help is an excellent thing so long as it does not help people to do injustice to others, and it is a scandalous injustice that well-to-do people can take advantage of the privileges of the Alliance and obtain their medical attendance at starvation rates. However, the President's address, on the whole, was fair in tone, and he suggested a round table conference with the representatives of the medical profession—a proposition which we imagine will be cordially welcomed. In the discussion that followed a good many offensive things were said about medical men, one member going so far as to state that the matter would have to be fought out in the House of Commons, where they (the friendly societies) were the "pets of both political parties." If a spirit of that kind prevails at all generally, then any conference with the profession is likely to be mere waste of time.

Heredity in Pulmonary Tuberculosis.

Since the discovery of the tubercle bacillus, medical opinions with regard to the heredity of pulmonary tuberculosis has undergone a profound change. Thirty years ago, a history of consumption in a family made the most optimistic physician shake his head sadly and frightened life assurance directors almost out of their wits. Nowadays the tendency is all the other way, and there are not wanting those who assert that family history is practically negligible if the individual in himself is healthy and lives an open-air life. In this connection, a paper from the pen of Professor Karl Pearson, entitled "A First Study of the Statistics of Pulmonary Tuberculosis," which has just been published in the Drapers' Company Research Memoirs, is worth study. The number of cases of tuberculosis dealt with was small, namely, 383, but the facts relating to these patients were elaborately worked out, and are handled by Professor Pearson in his usual masterly fashion. The people affected were the middle and lower classes of the inhabitants of Manchester, and Professor Pearson concludes from his study that it proves the all-important genetic fact that the diathesis of pulmonary tuberculosis is undoubtedly inherited, and that the intensity of the inheritance is comparable with that found for normal physical characters in man." He even goes so far as to say that on broad outlines there is no ground for supposing that environment influences the tubercle-disposed man more than the other. Coming from such a source, these views cannot but carry much weight.

A Medical Slander.

It says much for the general good-nature and self-control of the medical profession that there are comparatively few occasions on which their differences lead to an appeal to the law courts. Indeed, the recent conviction at Glamorgan Assizes of a Barry medical man of grave slander against a brother practitioner, carries with it an air of unfamiliarity that is in itself reassuring. The plaintiff, Dr. Kent, of Barry, brought an action against another practitioner in the same town, Dr. O'Donnell, for having uttered at a meeting of the local Education Committee the following words:—"As a medical man I will say fairly and squarely that I cannot support Dr. Kent for any position, because he does not behave as an honourable medical man should to his brother practitioners. He is thought to be a blackleg in his profession." The defendant was unable to bring adequate evidence to support these serious statements. On the other hand, it was shown that although some years ago there was some question as to the ethical propriety of Dr. Kent's return to practise in Barry, yet, on the whole, his action seems to have been approved by the majority of the local medical men. At any rate, there was sufficient doubt to make any cautious man extremely careful in his public references to the matter. We are glad to say that Dr. Kent has vindicated his professional status and conduct, for after a careful trial by an impartial judge, the jury found that plaintiff had been slandered falsely and maliciously, and they awarded him £250 damages. The plaintiff's case was taken up by the London and Counties Medical Protection Society.

The Death of Mr. Thomas H. Wakley

The news of the death of Mr. Thomas Henry Wakley, F.R.C.S., one of the joint editors of the *Lancet*, will be received with universal regret by medical men throughout the United Kingdom. He was the eldest son of the famous Thomas Wakley, the founder of the *Lancet*, who fought many battles on behalf of the medical profession, and at one time sat in Parliament as member for the metropolitan constituency of Finsbury. His son, Thomas, who was educated at University College Hospital, London, and at Paris, held the post of surgeon and, later, consulting surgeon to the Royal Free Hospital. He made various contributions to surgical literature, but was chiefly known as joint editor of the great professional journal founded by his father. In social life he won many friends by the genial and unassuming kindness of his disposition and the unswerving uprightness of his character. In Freemasonry he occupied a prominent position. A fuller appreciation of his interesting career will be found in our obituary columns.

PERSONAL.

H.R.H. Prince of Wales will open the new buildings of the Medical School at the Glasgow University on April 23rd.

Dr. W. Black Jones, of Llangammarch Wells, has been appointed a J.P. for Brecknochshire.

Col. J. Lane Notter, R.A.M.C., presided at the Sessional meeting of the Royal Sanitary Institute held at the Parkes Museum last night.

Professor Jacobs, of Brussels, will read a paper on the "Radical Cure of Prolapsus Uteri" at the British Gynæcological Society on Thursday next.

The Lord Chancellor has placed the name of Dr. Alfred H. Carter on the list of county magistrates for Worcestershire.

Sir Frederick Borden, the Canadian Minister of Militia and Defence, who is coming to the Colonial Conference with Sir Wilfred Laurier, is a medical man. He has long served in the Canadian Militia as a surgeon, and now holds the rank of lieutenant-colonel.

Dr. Fred Evans, Cardiff, has terminated his official connection with Whitchurch, and thus brings to a close a family connection extending for nearly a century. His friends took the opportunity of presenting him with a gold watch.

Dr. William Henry Drummond, Professor of Medical Jurisprudence at Bishop's University, Montreal, and one of the best known men in Canada, has been stricken with paralysis at Cobalt.

Dr. King Houchin, the deputy coroner for East London, has retired from that position, in which he has been succeeded by Dr. James Godding.

Dr. Robert Rentoul of Liverpool,, will deliver a lecture at the Incorporated Institute of Hygiene, London, on Monday next, on "Woman's Health: Our Greatest National Asset."

The will of the late Sir Michael Foster, K.C.B., F.R.S., late Professor of Physiology in the University of Cambridge, and M.P. for the University of London, has been sworn at £4,294.

Surgeon-Lieut. Colonel A. P. O'Connor, C.B., Royal Army Medical Corps, has taken up the duties of principal medical officer, Northern Command, vice Colonel M. D. O'Connell retired.

A CLINICAL LECTURE
ON
ACROPARÆSTHESIA. (*a*)

By ARTHUR J. WHITING, M.D., M.R.C.P.,

Physician to the Tottenham Hospital, Assistant Physician to the Mount Vernon Hospital for Consumption and Diseases of the Chest, and Dean of the North-East London Post-Graduate College.

GENTLEMEN, I wish to speak to you this afternoon about a disease which almost exclusively affects the poor, and of them particularly certain middle-aged hard-working women. It is quite common in working-class districts. As far as my own experience goes, it has seemed especially common in this densely-populated poor part of London. Although it is common and has been known for perhaps a score of years or more, even yet it is not generally recognised by the profession. It is the cause of much suffering and disability, both of which may in some degree be obviated, yet because its nature and ordinary exciting causes are not appreciated the suffering and disablement too often go unrelieved. This disease has been called acroparæsthesia, and it is one of a group of maladies known as angioneuroses—neuroses because apparently a nervous affection, yet no definite structural disease of the nervous system has been found in them; and angioneuroses because the symptoms are mainly, if not entirely, vasomotor. We know that that part of the nervous system which presides over the blood vessels is the sympathetic nervous system, so we must assume that there is functional disease, so-called, of some part of the sympathetic.

Let me remind you of the structural plan of the sympathetic nervous system. On each side of the ventral surface of the spinal column is a ganglionated cord extending from the head to the coccyx; joining obliquely the ganglia of these cords are branches coming from the spinal cord with the spinal roots—the *rami communicantes*—which are themselves in continuity with descending fibres transmitting impulses mainly from the vasomotor centres in the medulla, but also from similar centres in the cord and in the cortex cerebri. From the sympathetic ganglia at all levels fibres pass to the blood vessels generally, the viscera, glands, etc., conducting vasomotor impulses to the vessels, motor impulses to the unstriped muscle-fibre of the viscera, secretory impulses to the glands, and possibly also trophic impulses to the tissues.

Before discussing acroparæsthesia itself, let me enumerate some of the principal functional disorders of the sympathetic nervous system. For our purpose they may be divided into two main groups—subjective and objective. To mention the objective disorders first, we are all quite familiar with the condition known as "dead fingers," a whiteness and numbness of the fingers occurring in apparently healthy people, lasting for a short time and then passing away with perhaps some pain. This hardly passes the physiological limit, but there is an exaggeration of the same, or at least, a similar and more pronounced condition well known as Raynaud's disease—a local syncope or angiospasm followed by a local asphyxia or regional cyanosis—a vaso-dilation, which may go on to gangrene. In the first instance there was angio-spasm; in the second angio-spasm followed by vasomotor paralysis. There is a third type, one of pure vasomotor paralysis, in which the feet become red, painful, and cyanotic when they hang down, an instance of which some of us saw in the out-patient room a short time ago, known as erythromelalgia (I will send round a picture of this). Then there is the condition we have several times observed together, of angioneurotic œdema, transitory circumscribed œdamatous swellings of the skin and subcutaneous tissues (I send round a photograph you have seen before of this condition in the lip of a girl). These are the types of the objective angioneuroses.

The type of the subjective angioneuroses is one—the subject of this afternoon's lecture, acroparæsthesia which, however, has been known as "vasomotor neurosis of the extremities," a name given by Nothnegel, and as "spastic vasomotor neurosis" to distinguish it from erythromelalgia, called "paralytic vasomotor neurosis of the extremities." The name acroparæsthesia was given to the condition in 1890 by Schultze. Paræsthesia are usually described as abnormal subjective sensations other than pain and numbness, as tingling (pins and needles), burning, crawling sensations, but in acroparæsthesia pain is nearly always, and numbness sometimes, present, so to some extent the term is a misnomer. We are familiar with the use of the term acro (meaning an extremity) in acromegaly or largeness of the extremities. By acroparæsthesia then is understood abnormal subjective sensations referred to the extremities—the hands and feet.

I will now describe to you three or four examples of the condition and bring the respective patients before you, after which I will describe the disease more in detail, and then shortly discuss its pathology, diagnosis, prognosis, and treatment.

Case I.—Mrs. R., æt. 59, a widow, first came to the hospital in January, 1904, complaining of a sensation of deadness in the hands and of severe pains in them, which woke her up in the morning, both being worse after having used her hands in washing on the previous day. She first began to be troubled in this way some seven years ago, and the attacks became aggravated two years later when, on the death of her husband, she was obliged to undertake more washing. There was nothing of the same sort in the family, the father died at a good age from a stroke and the mother was still alive, æt. 94.

There was no evidence of alcoholic poisoning, and the knee jerks were brisk. The disagreeable sensations extended above the elbow on the right

---

(*a*) Delivered at the North-East London Post-Graduate College, Tottenham Hospital, N., on February 14th, 1907.

side, but never higher than the wrist on the left. The finger tips during the height of the attack were numb, *i.e.*, slightly anæsthetic or hypoæsthetic. Under treatment, and especially coincident with a lessening in the amount of washing an improvement soon became manifest, and in November of last year (1906) she reported that her hands were much better, but not quite right yet, the tingling and numbness still turned to what she described as "dreadful pain," but she said it "was nothing like it had been." The attacks came on about 6 or 7 a.m., shortly before getting up, and would last for several minutes in their severity. She still had to rub her hands before she could dress herself.

Case II.—Mrs. P., æt. 31, the wife of a labourer, came to the hospital on the 2nd of April, 1906, complaining of numbness and pain in the hands, which came on at night after getting warm in bed and were much worse after having done washing during the previous day. She had suffered in some degree from such sensations for four years, but they had latterly become more distressing. There was also, she said, some swelling of the hands at the time. She had to work hard, and was much hampered in her work because she was unable to grip anything till mid-day. Her sleep was much disturbed. She had been troubled with dyspeptic symptoms. She improved considerably under treatment and less work, and particularly so when she gave up washing for other people. She discontinued attending hospital about the end of June.

On November 22nd last she returned with the story that during the cold and wet weather of the few days previous she had had tingling and "numby" sensations of the hands, but they "did not swell yet."

On February 7th (of this year) she reported that her hands had been worse during the frosty weather. The pains now went up to the shoulders, and she could not hold things in her hands, although she could feel them. She was frequently breaking crockery and had more than once cut herself with the fragments. She had not been doing more washing than usual. The sensations of the numbness and gnawing in the hands began directly she got into bed, so that after her weekly washing day she could hardly sleep at all, and the sensations remained insistent for two or three days after. The hands swelled and went a little shiny at the same time. She was unable to finish dressing herself in the early morning and had to come downstairs, have breakfast, and then return to the room to complete her toilet. Hearing in the out-patient room the complaints to me of another patient (the case I have just described), she said when her turn came "that lady must be like I am."

Case III.—The third patient I shall show you is a married woman, æt. 45, the wife of a fitter. She came to the hospital on November 26th last complaining of pain in the left hand, which would wake her up at night and prevent her sleeping. It came on for the first time in October of the previous year, and the paroxysms in succession lasted for about six months, that is until the warmer weather began. They returned with the return of cold weather in October last. The pain in each paroxysm started, she said, in the middle finger and then spread to the whole hand, which went numb and tingled (pins and needles), but it did not change colour. The pain was very bad after doing her own washing so that, she said, she did not get any sleep at all the next night. She found that if she hung it down out of bed feeling returned to the hand until she began to use it again. When it was bad she was unable to carry anything with it and could not pick up anything with it. Physical examination of the heart showed nothing abnormal, and the bowels and catamenia were regular. When she came to the hospital at the end of last month (January 31st) after, as you will remember, a season of very cold weather, she reported that the sensation now affected her feet. For nearly a week she had had hardly any undisturbed sleep. The pain in the left hand would wake her up a dozen times in the night. In the morning she would be unable to shut her hand until after she had passively moved it about for ten minutes or so, and even then she could not dress herself. properly, only with difficulty. Indeed, during the whole of this time she had not been able to use it properly for anything. The finger tips she expressly said felt numb.

These cases I offer to you as fairly typical instances of the condition I am describing. The cases I have shown you are, or may be called, middle-aged women, and that as I have already hinted, is the rule in this disease. In a group of 162 cases collected by Cassirer there were only 12 men, and among 129 cases in 106 the age was between 30 and 60.

About three-quarters of the recorded cases, like the three I have shown you, have been engaged either in washing, scrubbing and other occupation requiring that the hands should be used in water of varying temperature or engaged in sewing or some kind of needlework requiring prolonged use of the fingers. In a number of a group of 43 cases collected by Collins the symptoms could be brought on by immersing the hands in water.

Among other conditions noted as contributing causes are dyspepsia (Collins found some intestinal disturbance in 57 out of 100 cases, and in our second case a complaint of this nature was made), alcoholism, the climacteric, ovariotomy, parturition, pregnancy, influenza, and anæmia. Anything, however, that lowers the general health seems to predispose.

The attacks mostly come on in the early morning between 4 and 6 a.m., but the sensations may persist in a slight degree constantly. When not thus persistent it is said that an attack may occur if the patient falls asleep during the day. It is the rule that the paroxysms are more in evidence in cold and especially in frosty weather; our second patient said she could tell when there would be frost on the ground in the morning by the sensation in her hands during the night.

The classical distribution is in the fingers, but it may be very rarely (as in our third case) in the feet. It usually affects one hand more than the other, and sometimes it commences in one finger. It sometimes affects the tip of the tongue and the lips. In the upper limbs the sensations may extend to the elbow or even as high as the shoulder.

In the majority of cases there are no objective signs whatever, and of these subjective cases many show merely the paræsthesiæ of creeping, tingling, etc.; these should probably be looked on as the pure cases of acroparæsthesia. According, at any rate, to my own experience, still more have somewhat severe pain in addition. In two other groups there are objective signs; in one of these, along with the subjective signs, there is a degree of blunting of sensibility—hypæsthesia; and in the other there are obvious objective vasomotor disturbances, coldness of the hands, pallor, even dead fingers, or as in one of our cases swelling of the hands and shininess of the skin, but the last cases abut on the type of Raynaud's disease on the one hand and erythromelalgia on the other. Thus the types may be described as (1) paræsthesia cases, (2) pain cases, (3) hypæsthesia cases, and (4) objective vasomotor cases.

There is nothing definite in the heredity of these cases, perhaps 50 or 60 per cent., have some neuropathic tendency, but this might apply to many non-nervous diseases, and it is conspicuous, as in our three cases, that there is little, if any, unusual indication of hysteria or neuræsthenia.

There is in this disease no morbid anatomy, so its pathology must be largely conjectural. Without troubling you with the different, but largely coinciding, views that have been held, I would merely say that the weight of the evidence points to the anatomical substratum as a vasomotor spasm and a consecutive stimulation of the sensory nerve endings (as a boy's fingers might tingle and pale or flush after snowballing). There seems in many cases an element of toxæmia or auto-intoxication as there is not only in such obvious things as alcoholic neuritis and facial paralysis of Bell's type, but also in urticaria and perhaps angioneurotic œdema. To my mind a fair simile is with writer's cramp and other trade spasms, and I suggest we may look upon the condition as an occupation—neurosis, the stress of which falls on the vasomotor mechanisms of the extremities—an angio-spasm, and is brought about on the one hand by exposing the hands or even the feet to extremes of heat and cold (in predisposed persons), and on the other by a coincident over-exertion of the fingers in executing fine movements. It is noteworthy that the disease process, whatever it is, is not in any ordinary sense progressive, even eighteen years hava been known to elapse without further development—that is almost as long as the disease has been recognised.

About diagnosis there is very little that needs saying. An ordinary conclusion that is come to when these cases are met with in practice is that it is a form of peripheral neuritis, but besides the absence of anything characteristic of a multiple neuritis the very fact that the symptoms come and go in the way they do negatives this view. However long it lasts, moreover, there is never any muscular atrophy and the knee jerks remain brisk, and we must remember that the latter is a very sensitive reaction. For example, we know that the knee jerks may remain absent for years after recovery from a slight attack of diphtherial neuritis. Still, in the early days of observing such cases, the beginning of tabes, or of diabetic or other neuritis, or even of a threatened cerebral thrombosis (where the symptoms are one-sided) might be thought of—it would not be necessary, I think, to keep these in mind for long. Acroparæsthesia has, in fact, a remarkably definite clinical picture.

As to prognosis, recovery under treatment and general management, partial, if not complete, is the rule. But cases may last for years. In any event life is in no wise threatened.

In treatment the main thing is to modify or regulate the occupation. I have thought the disease might well be called the "charwoman or washerwoman's disease." Let patients be recommended to cease working in these ways as a man showing symptoms of lead-poisoning might be advised to take up some other occupation than that of a house-painter. Let the general health be brought into as good a state as possible, giving, if necessary, iron, quinine, strychnine, arsenic and other general tonics. Dyspepsia has been thought to have a causal relation and certainly nothing but good could come from removing that and intestinal disturbance likely to lead to auto-intoxication. For the general lability of the vasomotor system, obviously present in some cases, bromide in addition might be tried. At any rate, it has seemed to be of service in some cases. Ergot has been suggested on the one hand and nitrites on the other to act directly on the blood vessels. I have no recommendation to make of either from my own experience. As purely symptomatic forms of treatment, gentle faradism, especially in the dry form with the wire brush, has been advised, also the constant current and static electricity. Other methods suggested have been Swedish exercises, liniments with friction, and even hydropathic treatment, including salt-water bathing, but until a fairly advanced stage of recovery is reached the latter methods would seem rather hazardous.

The great thing I would suggest is to first recognise this highly disabling malady and then to attack it by a change in the occupation and every-day life.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Sir Lambert H. Ormsby, M.D., F.R.C.S., Senior Surgeon to the Meath Hospital and to the National Children's Hospital, Dublin, on "Diseases Peculiar to Children."*

ORIGINAL PAPERS.

ON THE PRESENT POSITION OF THE TREATMENT OF TUBERCULOSIS BY MARINE CLIMATES. (*a*)

By WILLIAM EWART, M.D.Cantab., F.R.C.P. Lond.

Senior Physician, St. George's Hospital, London, etc.

An examination of some of the principles of marine climatic treatment and of the requirements of the pulmonary affection, was the subject of the address, which began with some general remarks on Thalassotherapy, or Sea-treatment (sea-air, sea-water, sea-bathing, sea-voyages, and the pharmacology of the sea), and with a brief reference to Quinton's subcutaneous sea-water infusions. *Ocean climate* differs from all others in its exclusively marine character and its *equability*, in contrast with the *Sea-coast climates* which are the *most variable* and offer endless combinations between the features of the coast and those of the sea, none of them being the ideal one for consumption, because not always at its best, whilst some may prove to be *too protective* in the individual case, and others *too active* for some of its complications.

(*a*) Abstract of Opening Address at the Hastings meeting of the Balneological and Climatological Society, March 16th, 1907.

Climate and open-air can take no direct effect upon the bacillus; and the beneficial *effects of the seaside and its sea-air* are mainly dependent upon the patient's power of "reaction" on the one hand and, on the other, upon the all-important effect upon the tendency to catarrh.

Touching the *forms of tuberculosis*, Nathan Raw has recently urged an etiological and clinical distinction between the infection from the "bovine" bacillus and that from the "human" bacillus, which agrees well enough with our climatological data and practice, all assuredly "bovine" infections (surgical, glandular, scrofulous, cutaneous, serous, and visceral other than pulmonary) being almost unreservedly benefited by the sea. This is not always the case with the pulmonary affection, for which alone the "human" bacillus infection would be to blame.

The multiple types evolved by individual predispositions (constitutional, organic, and functional) fall into the two groups: *Uncomplicated Tuberculosis* and of *Catarrhal Tuberculosis, or Phthisis Pulmonalis.* In the first group, tuberculosis may be "latent" and healing, or "declared" and spreading. In the second (which includes the acute caseous form) catarrh is the chief agent of mischief as well as the first object of climatic treatment. To describe as "consumptives" the bearers of latent and spontaneously-healing tubercles, would be inaccurate; and, on the other hand, "tuberculosis" does not depict the varied miseries of catarrh, of pneumonia, and of caseation in the painful record of advanced consumption. Bacillary infection ("tuberculosis") may mean little or much damage, but "consumption" (or, in the Greek vernacular, "phthisis") is always a big affair, and in pathology it spells "catarrh." We now have to reverse the famous dictum of Niemeyer and to recognize that "the worst fate that can befall the patient infected with tubercle is that he should develope phthisis."

The Aerotherapeutics of tuberculosis are thus practically speaking, those of catarrh; but whereas sea-air is curative of some forms of simple non-bacillary bronchitis, it is not always sufficiently dry for the cure of catarrh based upon tubercle. Whether we consider the meteorological factors or are guided by the results observed clinically, it cannot be gainsaid that the altitude is likely, and proves itself, to be more effectual in obviating early catarrh and curing it at any of its stages than the climate of the coast. In this connection, Dr. William Gordon's investigations upon the influence of wet winds are most suggestive, although he has not hitherto formulated any conclusions beyond the broad fact that the prevalence of phthisis is definitely increased by it.

But as we have not any altitudes available in this country we should adopt an opportunist policy and make the most of our unrivalled assortment of "protecting" and "bracing" seaside resorts by careful selection of cases, by progressive elaboration of their clinical treatment, and by measures tending to correct any imperfections of the local climates. The "bracing" resorts possess the highest restorative efficiency; but their suitability for pulmonary tuberculosis is limited. The criterion of fitness for these climates is integrity of the mechanisms of "reaction," which are dependent above all upon cardio-pulmonary efficiency. Thanks to the possession of sound lungs and of a sound heart, the great majority of cases of tuberculosis other than pulmonary (surgical, scrofulous, cutaneous, &c.) are eligible for the bracing resorts and derive there the greatest benefit. Many cases of "latent" pulmonary tuberculosis are for analogous reasons eligible. But "declared" pulmonary tuberculosis even at an early stage, and "early phthisis pulmonalis," cases claim the most careful climatic management, with a view to the avoidance or the cure of catarrh, and need protection from the stronger kinds of sea-air. All cases of "advanced" phthisis, as well as the group of "chronic quiescent phthisis" admit of no alternative; they are to be sent to the milder stations.

The present position of the treatment by marine climates rests upon the recognition of the fact that mere "airing" and "salting" are not competent of themselves to cure the pulmonary complications of the disease when it affects the lung. "Open-air" and "sea-air" are a basis for treatment, but cannot supersede the scientific methods of modern therapeutics. The marine resorts should add to their natural resources increased facilities for a systematic treatment planned upon a combination of the hospital idea and of the sanatorium idea. On this scheme alone can they look forward to an increased curative efficiency.

Meanwhile a much greater field of usefulness is open to them in *prevention.* The sanatorium movement is gravitating in that direction; but the seaside is, *par excellence* the place for the "Prevention Sanatorium" or "Preventorium," the inmates of which should be recruited from the most threatened stages and from the most dangerous surroundings. This is the direction in which a more extensive and systematic use of our marine climates is indicated. Their wider employment for the extirpation of tuberculosis in the coming generation is a possibility and a public duty.

Lastly, the task of improving the local opportunities for climatic treatment is not beyond the skill of modern engineering. Some of our prosperous stations rejoice in a sandy soil suitable for the growth of the pine; others in a mild and sunny hinterland; others in cliffs combining available shelter and altitude. Among them, the city of our welcome is not the least favoured, and may yet secure a future of unequalled efficiency in the struggle against tuberculosis.

AN IMPROVED GAG.

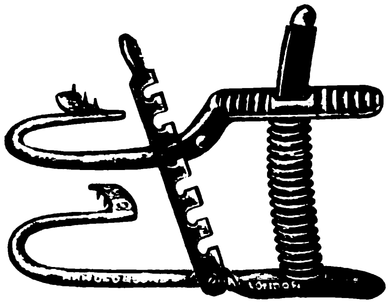
BY JOHN WARD COUSINS.

Senior Surgeon of the Royal Portsmouth Hospital and of the Portsmouth and South-East Hants Eye and Ear Infirmary.

Gags form a class of instruments which require careful adjustment for every surgical case in which they are employed. They are made in all sorts of shapes and sizes; but I do not know of any gag which is sufficient for every purpose, and can be easily adapted to every mouth.

The instrument exhibited in the engraving is a very convenient and simple contrivance, but I do not claim that its qualities render it superior to every other device of the kind. It has, however, in my hands proved very serviceable in staphylorrhaphy, and also in many surgical operations of the mouth, pharynx and tongue.

In the *British Medical Journal* of February, 1888, I ventured to suggest a gag in which the bars were expanded by a strong spiral spring, and fitted with a rack and screw adjustment. It was especially designed for minor operations, and also for the purpose of dental surgery. The improved gag which I now propose, consists of only one strong stem surrounded by a central spring similar to the instrument introduced by Mr. Armandale some time since, and recently modified by Mr. Arbuthnot Lane. The upper bar slides over a round stem, and is attached to the end of the spring, the lower bar is fixed, and both of them are furnished with projecting finger plates, so as to facilitate rapid adjustment and removal. When introduced into the mouth the dental surfaces are expanded by the spring, which is at once compressed and jammed on the stem by the tilting of the bar.



The gag can then be securely fixed in any position by a steel lever, fitted with a series of notches for receiving a tooth attached to the upper bar.

The dental plates can be introduced into the mouth with or without an indiarubber cover, according to the condition of the gums and teeth. Messrs. Arnold have made for me a right and left gag, but I have used the same instrument on both sides of the mouth.

A CASE OF

CHRONIC PANCREATITIS.

By W. I. de COURCY WHEELER, F.R.C.S.I.,

Surgeon to Mercer's Hospital, Dublin.

Considering their comparative frequency chronic diseases of the pancreas have not received the attention in surgery which they seem to deserve, more particularly as they are closely associated with such common affections as gastro-duodenal ulceration and catarrh, and inflammations of the gall bladder and bile ducts. From these conditions chronic pancreatitis arises by direct extension of the inflammation through the common bile duct. The presence of a stone in the pancreatic portion of the bile duct will also cause inflammation in the gland mechanically by the pressure exerted, as well as by the obstruction to the flow of the pancreatic juice. Many other causes are mentioned as responsible for an attack of chronic pancreatitis, thus syphilis has been shown to affect the pancreas in a similar way to the other organs in the body and changes due to the congenital form of the disease have been observed as early as the fifth month of uterine life. Tubercle, enteric fever, influenza, have all been thought accountable for various cases of pancreatitis and alcoholism is supposed to produce the same changes as are familiar in cases of cirrhosis of the liver, but as regards this cause it must be remembered that the relation between alcoholism and cirrhosis is extremely vague and has not been proven. The pancreas undergoes fibrous changes like the kidney and other organs as a result of endarteritis and general arterio-sclerosis. The following is a brief account of a case which first brought this subject under my notice.

"P. C.," æt. 35, was admitted into Mercer's Hospital in December last. He was emaciated and stated he had been losing weight for the past year. For six or seven years he had suffered from a dull gnawing pain in the right hypochondrium and epigastric regions, which usually remained for about two months, and then for a short interval disappeared. He never had ague-like attacks nor pain resembling biliary colic, nor was the pain in any way associated with the taking of food, although vomiting was a fairly constant symptom. The patient was not jaundiced on admission, except for a yellow tinge in his sclerotic, but he assured us that on several occasions when the pain was unusually severe he had become distinctly jaundiced. He always suffered from constipation, and on admission to hospital the stools were clay coloured and offensive. The urine was free from albumen, sugar, and bile. On examination of the abdomen no tumour could be felt, the liver was not enlarged, but there was an area of tenderness on deep pressure, which extended from above and to the right of the umbilicus upwards towards the eighth and ninth costal cartilages. The case was thought to be one of stone in the common duct, and operation advised. The patient was placed with a sand bag under the back at a slightly higher level than the liver, and the table sloped so that the head was slightly raised and the feet low. By this means, when the abdomen was opened, easy access was obtained to the liver, gall bladder and bile ducts, and the area of operation was rendered still more clear by the slipping down of the intestines by gravity towards the pelvis. The liver was raised up and the fundus of the gall bladder first examined, it was found healthy and slightly distended with bile. This alone was evidence against the blockage of the common duct by stone, but not conclusive evidence, for it has been shown that where chronic pancreatitis and stone in the common duct co-exist the gall bladder may be distended in contradiction of Courvoisier's law. The neck of the gall bladder was next examined and found to be included in a mass of adhesions which involved the colon, liver, duodenum, gastro-hepatic omentum and pylorus, and obliterated the foramen of Winslow. The next step in the operation was one of some difficulty and consisted in wiping away the adhesions with gauze sponges and freeing the various organs as far as possible. During this dissection the supraduodenal portion of the common bile duct was exposed and examined, and then traced downwards to the point where the duct becomes lost in the substance of the head of the gland, or, is found in a groove on its posterior surface. The head of the pancreas was now found to be enlarged, hard and nodular, having the feel of an organ in which a considerable overgrowth of connective tissue had taken place. No stone could be felt in the neighbourhood of the posterior surface of the head of the pancreas, but it was now evident that all the symptoms, the emaciation, the pain, and the indefinite attacks of jaundice and indigestion could be accounted for by the pancreatitis. Drainage of the gall bladder was therefore decided upon, the rationale of the treatment being that through the intermediary of the bile passages the pancreas itself is drained, and that there is therefore a relief of tension in the ducts, a consequent subsidence of the inflammation in the head of the gland, and *parri passu* the pressure on the third and fourth portions of the common duct is diminished and the biliary obstruction gradually disappears. It is doubtful if such a result can be obtained in those cases where cirrhotic changes are marked and atrophy of the head has taken place; but these changes are only brought about in the pancreas after a prolonged period of inflammation, and in all likelihood by the time such had occurred glycosuria or other untoward symptoms would have arisen to contraindicate operation. On the other hand the symptoms of chronic pancreatitis lead one to operate long before the hypertrophic stage has given place to marked cirrhosis. I would like to draw attention here to the extreme difficulty of detecting, by the sense of touch, inflammation of the head of the pancreas, unless it is well marked. Opportunities for examining the pancreas in the living are not numerous, and the feel of the gland may create erroneous impressions as to whether it is healthy or inflamed. Robson calls attention to this and describes a typical case of inflamed pancreas as feeling like a hard waxen cast. There appears to be no doubt, however, that it is still more difficult to see changes in the pancreas at a necropsy, for the early swelling due to retained secretion and engorged blood vessels disappears at death. A very careful peritoneal toilet was made, as although in healthy animals the bile has been proved in most cases to be sterile and incapable of producing septic peritonitis, yet in the presence of such conditions as chronic pancreatitis and gall stones, streptococci, staphylococci, and above all the bacillus coli have been cultivated from the bile. The gall bladder was opened and a large drainage tube inserted in the manner recommended by Moynihan and Robson. The tube was stitched in by two layers of sutures in such a way that when it loosened a valvular opening remained in the gall bladder favouring rapid closure of the fistula. It is well to bear in mind, however, that in order to cure inflammatory conditions, whether in the pancreas or in the gall bladder and bile ducts, prolonged drainage is sometimes necessary, and the rapid closure of the fistula should not be encouraged, the reappearance of bile in the stools; the disappearance of jaundice and the absence of micro-organisms in the bile are factors which help to decide when sufficient drainage has been obtained. In my case the tube loosened and was removed on the ninth day after operation; the fistula closed in the following fortnight, and the patient was allowed home one month after his admission into hospital. It is worthy of mention that the patient vomited bile repeatedly on the day after operation and suffered in consequence from insatiable thirst; the vomiting was produced probably by the stimulation of the liver and the filling of the ducts with bile during the operation, and was gratifying inasmuch as it showed, at all events, that the ducts were patent. The bile did not flow extensively through the tube until the evening of the second day, and the stools became normal in colour about nine days after operation. The man is at present working as a labourer, and is free from all pain, but at times he notices his stools become light in colour. The onset of chronic pancreatitis, as in my case, may be very insidious, the patient complaining of such symptoms as indigestion, flatulence, a dull ache above the umbilicus from which he is sometimes free, constipation and clay coloured stools. Sometimes indeed, the stools are bulky and quite out of proportion to the amount of food eaten From such a train of symptoms no diagnosis could be made, but if following on them the patient shows signs of even slight biliary obstruction, the jaundice increasing at every attack until it finally becomes constant, then, especially if the gall bladder be dilated the case is most likely one of either chronic pancreatitis or cancer of the head of the gland. In the absence of dilatation of the gall bladder a stone in the common duct must be suspected. The jaundice in the case of stone is often of a less permanent type than that produced either by malignant disease or chronic pancreatitis, the stone is usually loose and acts like a ball valve, the jaundice, in consequence, coming and going, and being usually accompanied with the pain of biliary colic. From malignant disease of the head of the pancreas it is often impossible to diagnose simple chronic pancreatitis, and even when the abdomen is opened the same difficulty will be experienced in differentiating between hyperplasia and a malignant growth, as in similar conditions of the pylorus. Suffice it is to say that in many cases where a hopeless prognosis was given, simple drainage of the gall bladder produced an absolute cure.

In some cases the onset of chronic pancreatitis is marked by far more acute symptoms than the foregoing. There may be attacks like biliary colic, rigors, nausea and vomiting, severe pain in the right hypochondrium radiating across the abdomen to the left more frequently than towards the scapular regions. Intense jaundice, though not necessarily occurring with the first attack, usually becomes a prominent symptom. It is small wonder that with such an onset chronic pancreatitis has been mistaken in a number of the recorded cases for a stone in the common duct. It must be clearly understood, however, that the two conditions are associated, for if there be a stone in the common duct for any length of time, chronic pancreatitis will certainly supervene and co-exist with the stone. In proof of this in many cases in which a stone was removed from the common duct the head of the pancreas was found enlarged and sclerosed, necessitating deep incisions into its substance in order to remove a stone by the retroduodenal operation. If the stone is eventually passed the chronic pancreatitis usually persists and produces a train of symptoms which exactly mimic those due to the former internal blockage of the duct. From a diagnostic point of view, therefore, it will be seen that two errors are likely to be made. The first is of paramount importance, viz.:—It may be thought that a case of jaundice advanced in years, with a distended gall bladder, in which a tumour can be felt and emaciation is a marked symptom, must necessarily be malignant disease; this is disproved by the recorded cases which demonstrate that a hyperplasia of the head of the pancreas with pressure in the common bile duct will produce a similar train of symptoms which disappear after operation. The second error of mistaking a simple chronic pancreatitis for obstruction of the terminal portion of the common duct by stone is not of so much clinical importance, since modern surgery teaches that in both conditions an operation is called for, and they are so closely associated that a differential diagnosis, though possible, need not be considered. In addition to cancer of the head of the pancreas and gall stones in the common duct, cancer of the liver and chronic cholangitis may lead to symptoms resembling chronic pancreatitis, and the possibility of mistaking any of these conditions for malaria must always be borne in mind. The relation of chronic pancreatitis to diabetes is relevant in one or two particulars to the surgery of the gland. In chronic pancreatitis, arising as it usually does from some extension of inflammation up the duct, the islands of Langerhans are not early involved, and there is apparently no interference with the internal secretion in these cases. Glycosuria is not present until late, but when it does appear, the time for operation usually is passed. In such cases of chronic pancreatitis diabetes is anticipated and prevented by timely operations. Occasionally glycosuria is an early symptom of the inter-acinar type of pancreatitis, the inflammation commencing within the gland and rapidly attacking and destroying the islands of Langerhans, determines the presence of sugar in the urine before other symptoms have exhibited themselves; such a condition of affairs occurs in cases of amyloid disease.

Examination of the urine and fæces will give valuable information in cases of chronic pancreatitis and materially help in building up the diagnosis. The clay-coloured stools are not accounted for so much by the absence of bile as by the presence of undigested fat. Bile in most cases of pancreatitis has been found by chemical means in the fæces, the only cases where it is absent or present in very small quantities are those in which there is a carcinoma of the head of the gland.

Evidence of incomplete proteid digestion in cases of chronic pancreatitis may be found by the presence of undigested muscle fibre in the stools. Mayo Robson points out that the fæces are acid to litmus in cases of early pancreatitis, but alkaline in simple jaundice, a useful clinical test, if future experience shows it to be reliable. Sahli invented an ingenious test to show insufficiency of pancreatic digestion. A gelatine capsule hardened with formaline and containing iodoform is swallowed by the patient. The capsule resists gastric digestion, but is rapidly acted on by the pancreatic juice, in consequence iodine will appear in the urine in from four to eight hours when the pancreatic secretion is sufficient. The presence of alimentary glycosuria is another diagnostic sign worthy of consideration. Two or three ounces of sugar are given before breakfast and the urine tested in a couple of hours. When sugar is present, disease of the pancreas is suspected, and in ten out of fifteen cases where there was alimentary glycosuria and on which a *post mortem* examination was obtained, marked chronic pancreatitis or cancer was found. This test was based on the experimental work done in connection with the relation of pancreatitis to diabetes, when it was shown that although removal of a portion of the pancreas did not produce diabetes, yet the gland was only imperfectly able to perform its duties on carbohydrate metabolism, and so if an animal with only a portion of the pancreas, was fed on large quantities of carbohydrate, sugar temporarily appeared in the urine. The presence in the urine of fat splitting ferments is mentioned among a host of other signs based on chemical analysis, as being in favour of the presence of pancreatitis.

THE OUT-PATIENTS' ROOM.

METROPOLITAN HOSPITAL.

Emphysema aud Blood Pressure.

By Leonard Williams, M.D., M.R.C.P.,

Assistant Physician to the Hospital; Physician to the French Hospital in London.

This man, æt. 52, is obviously suffering from emphysema. He is not a player in a brass band, nor is he employed in any of those trades, such as glass-blowing, which are usually considered as predisposing causes of the disease. He is, indeed, a person who, so far as his lungs are concerned, leads a tranquil life, because he is a clerk. I say he is obviously suffering from emphysema because his appearance is sufficiently characteristic. People suffering from this disease have a distinctive physiognomy. They are always cyanotic and generally dyspnœic but their cyanosis is out of all proportion to the amount of their dyspnœa. The dyspnœa is not very marked when they are quiescent but it becomes very much aggravated on slight exertion. I have often called your attention to the fact that dyspnœa on slight effort characterises a condition upon which I have so frequently insisted, namely, functional high arterial tension, and we must be careful not to mistake this condition for emphysema. Fortunately, emphysema is generally very easy of diagnosis. Its pathology, however, is a vexed question. There is the inspiratory theory, the expiratory theory, and the primary degeneration theory. I am not going to discuss these with you, because I do not think they are of importance. The only one which I regard as of any real moment is that which my friend, Dr. Harry Campbell, has brought forward, namely, the theory of primary degeneration of the elastic tissue in the lungs. According to his view, the elastic tissue wears out, and in order that the all-essential elasticity of the lung may be kept in existence, Nature has put this elastic tissue on the stretch, with the result that the lungs occupy a greater space and the thorax becomes enlarged in all its diameters. This theory has never, to my mind, received as much attention as it deserves.

You have often heard me say that emphysema is to the lung what chronic interstitial nephritis is to the kidney. Chronic interstitial nephritis we know to be associated with high blood pressure in the systemic vessels; emphysema is associated with high blood-pressure in the pulmonic vessels. In interstitial nephritis we often have hæmaturia; in emphysema we often have hæmoptysis. The essential condition in interstitial nephritis is fibrosis of the vessels in the kidney; the essential condition in emphysema is fibrosis of the vessels in the ultimate air-cells. The one is invariably complicated with hypertrophy of the left ventricle; the other is invariaby complicated with hypertrophy of the right ventricle. If you will look at this man now that his chest is bare, you will observe the characteristic barrel-shape of his thorax, the widened inter-costal spaces, and the prominent clavicles. You will notice also that he breathes as a woman breathes, that is to say, with the upper part of the chest, and not with his diaphragm; and when you come to examine him you will find all over his chest that percussion note which Sir William Gairdner used to call tympanitic dulness. The heart-sounds are difficult to hear because of the amount of lung which covers the organ; but some of you, I see, have already noticed the epigastric pulsation which is characteristic of this complaint. That epigastric pulsation tells the story of the enlarged right ventricle, which, owing to the atrophy of the pulmonary capillaries, has increased work thrown upon it. This atrophy of the pulmonary capillaries raises the blood pressure in the pulmonary artery, the right ventricle hypertrophies and eventually dilates, the liver enlarges, and the spleen also may become engorged. In this case there is no doubt whatever about the enlargement of the liver and the hypertrophy of the right ventricle, neither, therefore, can there be any doubt about the increase of blood pressure in the pulmonary artery. We know that the blood pressure in the systemic system must always be higher than the blood pressure in the pulmonic system. If it were not so, the medulla would shortly be starved and the patient would die.

On taking this man's blood pressure, however, we find that it reaches only 140 mm. Hg., which, for a man, æt. 50, must be regarded as well within the normal limits, so that it is quite obvious that the systemic system does not find it necessary to increase its own blood pressure in order to overcome the high pressure in the venous system. How are we going to explain this fact? Rindfleish explained it for us many years ago by showing that in emphysema wide communications were formed between the pulmonary arteries and the pulmonary and bronchial veins, thus relieving the tension in the former vessel, but allowing the blood to pass through the lungs without undergoing proper æration.

In most cases of emphysema the systemic blood-pressure is raised to the point where the systemic shall overcome the pulmonic pressure. But where, as in this man's case, the systemic pressure is not unduly high, we may be quite certain that the cause is to be found in those wide communications which Rindfleish has described. That is why these people have a degree of cyanosis which is sometimes very extraordinary. Such a degree of cyanosis as is present in this case, if it were due to any cause other than emphysema, would certainly necessitate rest in bed, and it would almost certainly be accompanied by orthopnœa. In emphysema, however, these vascular communications described by Rindfleish may permit a very high degree of cyanosis without very much distress. On auscultation, this patient illustrates what is, to my mind, one of the most characteristic findings in emphysema, and that is the high-pitched inspiratory sound followed by a low-pitched, and very much prolonged expiratory sound. There are, of course, frequently a great many added sounds, due to the chronic bronchitis from which these patients almost invariably suffer. In a patient who has died with emphysema, post-mortem examination generally shows a considerable degree of atheroma of the pulmonary artery. This is interesting from the point of view of the question of the possibility of high blood pressure being, of itself, capable of producing changes in the vessels which it affects. There is another condition, namely, mitral stenosis, which gives rise to high-blood pressure in the pulmonic system, and here, too, you will frequently find atheroma of the pulmonary artery. To my mind, no further proof is wanted of the fact that high blood-pressure is the primary event and arterial degenera tion is the secondary event, in the vast majority of cases of arterial degeneration, whether the high arterial tension be systemic or pulmonic. The finding of arterial degeneration in two conditions such as emphysema and mitral stenosis, in which the high arterial tension is admittedly primary, is to say the least of it, exceedingly significant.

With regard to mitral stenosis, it is interesting to note that it is not infrequently mistaken for emphysema. The mistake is more easily made than one would imagine, because the distinctive murmur of mitral stenosis is by no means always present. It is particularly liable to disappear when the back pressure in the lung has reached the point of giving rise to active pulmonary difficulty. The dyspnœa, however, of mitral stenosis is more or less characteristic because it is of a panting character, and there is no disproportion between the degree of cyanosis and the amount of dyspnœa. Moreover, in mitral stenosis the systemic blood pressure, inasmuch as it must always overcome the pulmonic, is always high. Except as a terminal event it never falls as low as 140 mm. Hg., because there are no communications, such as those described by Rindfleish, as occurring in emphysema, to relieve the pressure in the pulmonary vessels.

OPERATING THEATRES.

PADDINGTON GREEN CHILDREN'S HOSPITAL.

CASE OF UMBILICAL HERNIA, WITH SEPARATION OF THE RECTI.—**MR. ARTHUR EDMUNDS** operated on a girl, æt. 5, who had been admitted with a recurrent hernia in the middle line. The hernia was not very prominent but formed a distinct bulging with its apex at the umbilicus between the two recti, which were separated for about three inches. The condition had been present at birth, and was becoming more marked, indeed, the weakness of the abdominal wall had progressed to such an extent that the child was beginning to suffer from vague abdominal pains. Separation of the recti was, Mr. Edmunds said, by no means an uncommon condition in children, but it was not common to find the condition so aggravated as to demand operative interference ; usually the two muscles were only separated from each other, by about an inch and, as they develop with the growth of the child, they come automatically into their normal relationship and produce a firm abdominal wall. This natural process of cure was the rule in all the types of hernia at or above the umbilicus which occur in children. One usually finds that some simple strapping appliance or truss suffices not only to restrain the protrusion, but to cure the hernia. There remains, however, a small percentage of cases which resembles the adult type and in these operative interference was imperative. These fall into two main groups :—In the first we have a long elliptical swelling protruding between separated recti, usually with a marked projection just above the umbilicus. In the second type of cases the muscular separation was less marked and there was a simple rounded sac sometimes bearing the umbilicus on its summit, but more usually situated just above it. The present case belonged to the first type. Although the symptoms actually present were slight yet they were progressive, and the weak abdominal wall would have been a very serious drawback to the child as she grew older. Mere removal of the projection in the neighbourhood of the umbilicus, was, he pointed out, quite insufficient to cure these cases and it was necessary to approximate the recti, or better still to overlap them. An incision was made in the middle line, with its centre at the umbilicus, extending upwards and downwards about half way to the ensiform cartilage and the symphysis pubis respectively. The fascial structures were divided down to the peritoneum but this was not opened. There was no true hernial sac and any redundancy of peritoneum would speedily adapt itself to the altered conditions or at the worst remain as a perfectly harmless ridge. This point was, he remarked, of importance as it obviated that exposure of the abdominal contents which was always a serious matter in a young child. The rectus on the right side was now exposed and freed from its sheath throughout the extent of the incision ; the left rectus was freed posteriorly, a matter of extreme simplicity ; a suture was now passed through the whole thickness of the right rectus in such a way as to leave two ends projecting from its superficial surface and a loop on its deep aspect ; one of the free ends was taken and passed by means of a handled needle between the rectus and the posterior layer of its sheath as far towards the outer border of the muscle as possible ; the point of the needle was then made to penetrate the muscle, the suture completely unthreaded and the needle withdrawn. This suture when tightened drew the right rectus behind the left causing the two muscles to overlap by about half their width ; this manœuvre was repeated throughout the length of the incision, three or four sutures being employed. The free edge of the left rectus which was now anterior was sutured down to its fellow. The anterior sheath of the rectus was next stitched up and the wound closed. The wound healed by first intention and the child left the hospital after three weeks. When seen a year later the girl had improved in general health, had lost her abdominal pain and had a good firm abdominal wall.

Mr. Edmunds mentioned that he had done the same operation on another case in which there had been a well-marked sac as well as the muscular separation. The sac had been removed at a previous operation, but the relationship of the muscles had been left unaltered. The wound had healed normally but the scar had stretched, and it was obvious that the hernia was re-forming. The operation described above was performed with the result that a firm abdominal wall was produced with no tendency to protrusion.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

MEETING HELD FRIDAY, MARCH 15TH, 1907.

Dr. W. R. DAWSON in the Chair.

ABSCESS OF CEREBELLUM.

Dr. W. BOXWELL exhibited an abscess, in right lobe of cerebellum, taken from a boy, æt. 14 years, who, his mother said, had always been an idiot. About Christmas he was struck with a snowball behind the ear, where a lump subsequently arose. For a few days he had a discharge. He was brought into hospital on 8th January suffering from attacks of vomiting, and in a curious drowsy state. The large lump behind the ear was diagnosed as hematoma. He was then in a hectic condition ; he vomited everything given to him, and also at intervals irrespective of food. An operation was performed on 12th January, with a view to finding the condition of the lump and to ascertain if there were any disease in the antrum and sinuses. The lump was found to be a suppurating hematoma ; and, with a view to clearing out possible mischief in the mastoid cells, they were trephined, but no particular sign of disease was found. On further exploration a suppurating track was found leading down through the occipital bone, from which the pus was slowly oozing. This was found to lead under the base of the skull, and a large suppurating sinus was found. The track was drained, but no relief of the symptoms followed. The boy became more and more drowsy, and was again operated on the 25th, the skulls being trephined and the brain explored for abscess. None could be found. Five days afterwards the boy died. At the *post-mortem* there was found on the right side a large cerebellar abscess, which had opened of itself on the under surface, and a pool of pus was lying in the occipital fossa. On exploring the original suppurating sinus with an ordinary bent probe, it passed easily into the cavity, and the cavity had been slowly emptying itself through the sinus and the drain. Examination of the pus showed presence of ordinary pus cocci.

The **Chairman** asked if Dr. Boxwell considered there was any causal connection between the suppurating hematoma and the abscess, or whether the hematoma was altogether a different lesion which became infected by the sinus burrowing into it. It struck him that, for an idiot's brain, it was extremely well-formed and convoluted, and he would like to know if anything had been ascertained as to the boy's degree of mental weakness.

Dr. **Boxwell**, in reply, said the idea was that it was a direct infection from the bone. There was no sign of any mischief through the ear-duct, and there was no disease whatever in the antrum. Whether the hematoma became infected secondarily from the pus escaping through the hole in the bone, or *vice versa*, he did not know. The pus in the cavity was recent. The boy could give no history of himself. His mother said he had always been an idiot, and could not be trusted with a message.

(*a*) SARCOMA OF FEMUR; (*b*) TUBERCULAR KNEE-JOINT.

Mr. L. G. **Gunn** exhibited specimens of above. He did so, he said, because both were diagnosed to be the same condition. Both presented symptoms of chronic inflammation of the knee-joint, which was believed to be tuberculous. In one case the diagnosis was correct; in the other it was very much mistaken.

SACRO-COCCYGEAL TERATOID TUMOUR, WITH FORMATION OF METASTASES IN THE GROIN.

Mr. **Seton Pringle** read a paper on "A Sacro-Coccygeal Teratoid Tumour, with Formation of Metastases in the Groin." The growth had been removed from a man, æt. 57 years, who had first noticed it thirty-five years previously as a small lump in the middle line, behind the anus. Since that time the tumour had grown slowly, till at operation it measured fifteen inches over all, from lower to upper extremity, and eleven inches from side to side, extending from the upper border of the sacrum to the anal margin, and from outside the left margin of the sacrum to well on to the right gluteal region. Two metastatic growths, each the size of a large hen-egg, were present in the right inguinal region, one of these had appeared thirty-three years and the other twenty years prior to the time of examination. By the rectum the hollow of the sacrum was found to be full of growth, but, as the patient was most anxious for operation, the posterior extern pelvic tumour and the secondary glands were successfully removed. At the operation a pedicle of growth was found, extending through the coccyx, which had been almost completely destroyed, connecting the intern and extern pelvic portions of the tumour. The patient, unfortunately, died a year later in the country from intestinal obstruction. Mr. Pringle then described the macro- and micro-scopical characters of the tumour and glands, and gave a short *resume* of the literature of the subject placing the growth in the class of monogerminal teratoid tumours as described by Borst. In conclusion, he pointed out the case differed from recorded cases in three particulars:—(1) The late appearance of the tumour, most recorded tumours having been present at birth. (2) The comparatively simple structure of the growth. (3) The occurrence of metastases.

The **Secretary** (Professor A. H. White) recalled a case of a tumour in the same region which supported the view that such tumours were parasitic. It was from a girl of sixteen or seventeen. A tumour which had been small suddenly took on rapid growth, and contained portions that were typically cancerous, and others that were typically like round-celled sarcoma, besides almost every fully formed tissue that could possibly be found. In the case shown by Dr. Pringle the structure of the tumour was much less complex.

Mr. **Gunn** cited a couple of cases of similar tumours.

Dr. **Pringle** replied.

CEREBRO-SPINAL MENINGITIS.

Dr. **Harvey** exhibited slides from a case of cerebro-spinal meningitis—a girl, æt. 10. She had been perfectly well on the morning of the previous Monday. While swallowing a piece of liver she choked, and, not getting much relief, she was brought to hospital. There she developed great tenderness down the spine. She passed into a comatose condition; her eyes were open, but there was no cornea reflex. She died the same night. Next morning he drew off some fluid by lumbar puncture. The slides which he had prepared, showed a diplococcus in great numbers, even in the original fluid, and outside the cell. They were distinctly non-Gram staining. One of the slides showed a capsule round the cocci—which was said not to exist.

Professor White observed that the cocci shown were all stained much in the same way. In those which he himself had got the irregularity of the staining was most pronounced, some taking it deeply, others only slightly. The regularity in Dr. Harvey's specimens were probably due to the early stage at which the patient had died. With regard to the cocci which exhibited capsules, he had found the same in some of the organisms which he had got from certain cases this year. Weichselbaum and his school denied absolutely the existence of a round capsule in his coccus; but Jäger, who had considerable experience, stated that capsules were frequently seen. Between the supporters of the two there was considerable strife, both on that point and also as to whether the organisms were always negative to Gram. The former school say that those which were positive to Gram were not the specific organism at all. He mentioned the fact that sub-cultures of an apparently pure non-Gram staining organism became Gram-staining as showing that the question of staining was not yet settled.

Dr. **Day** asked if there was any history of discharge from the nose in the case. He had found it in all cases except one, and Continental observers had reported a diplococcus found in swabs taken from fifty per cent. of cases.

Mr. **Gunn** said he had seen the child in hospital, and no history of discharge could be obtained. He was inclined to think she had been ill for a longer period than the parents made out, and that the choking was probably some defect of swallowing. About an hour and a half before death there were five or six fairly typical spots on the child's limbs. After death he saw the body almost covered with them.

Dr. **Harvey**, in reply, said the preparation to which Professor White had referred as showing regularity in staining had been made from the original fluid; but on making some more that day he had noticed great irregularity in the staining; and the appearance of diplococci apparently much larger than the other cocci gave him the idea that the cocci had swollen out.

A TELEGRAM from Strasburg last week states that the small-pox epidemic at Metz had assumed alarming dimensions. The epidemic is seriously affecting trade and industry, and the military doctors, seeing that the civil medical men are unable to cope with the number of cases, placed themselves at the disposal of the town, and are vaccinating people in their homes. Owing to the serious nature of the epidemic the public rejoicings in connection with the Eastertide fetes have been abandoned.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.

Meeting held at the Town Hall, Hastings, on March 16th, 1907.

After a short address of welcome by the Mayor of Hastings,

Dr. **Wm. Ewart**, of London, introduced a discussion on the

PRESENT POSITION OF THE TREATMENT OF TUBERCULOSIS BY MARINE CLIMATES,

an abstract of which will be found on page 390.

Mr. **Henry Colborne**, M.R.C.S., read a statistical paper on the temperature, rainfall, bright sunshine, and climatic conditions of Hastings, covering a considerable period. After demonstrating the abundant amount of sunshine in Hastings, the highest record in the British Isles save the islands of the English Channel, he referred to the clearness of its atmosphere, when compared with our great cities which lost from three to four hundred hours of bright sunshine yearly through smoke alone, the yearly average in the City of London being 1,143 hours, while at the Kew Observatory there was an average yearly record of 1,568 hours.

Mr. A. **Scarlyn Wilson**, D.P.H. (St. Leonards-on-Sea) said examination of the mortality statistics shows that since 1898 there has been a marked decline in the number of deaths from phthisis registered in Hastings. This reduction is so great (nearly 35 per cent., comparing 1898 with 1906) as to make it reasonable to infer that the stream of phthisical patients which formerly flowed in this direction has been partially diverted into other channels, probably towards the inland sanatoria, which have recently sprung up. If other seaside resorts have been similarly affected, a great change must have taken place in the opinion of the medical profession as to the value of marine stations in the treatment of active phthisis.

Dr. **Anderson-Berry** (St. Leonards-on-Sea) heartily agreed with Dr. Ewart's illuminating address. He wished to emphasise one or two points: (1) That, as Dr. Ewart well said, there is no single method whereby phthisis may be successfully treated. Drugs have their place as well as open air and other hygienic methods. (2) That the patients who do well at marine stations are those whose opsonic index shows a considerable power of reaction present, especially when tested by injections of tuberculin. In answer to a question asked he would add that such a climate as that of St. Leonards is especially favourable in his experience to cases of emphysema upon which have been grafted tubercular processes.

Dr. **Bagshawe** pointed out that the late Dr. Henry Bennet was an early advocate of the treatment of phthisis by the open-air method. All his patients at Mentone were enjoined to have their windows open night and day, and to spend much time reclining in the garden. The importance of rest was especially enjoined. Looking back upon an experience of forty years at Hastings, he was able to point to a long list of patients who had lived through the active stages of pulmonary tuberculosis and had settled down to spend long lives, with arrested damage, some partially, some entirely cured. Such cases bore striking testimony to the advantages to be derived from a sheltered sea-coast climate such as Hastings.

Mr. **George Pernet** desired to call attention to the importance of general treatment in tuberculosis of the skin, especially as regards marine climates.

Dr. **Wethered** said that it might be accepted that the treatment of pulmonary tuberculosis in marine climates was practically one form of the "open-air" treatment of the disease. The essentials were an abundance of fresh air, a full, varied diet, and, in the earlier stages, skilled supervision in the matter of exercise. These requisites might be obtained *par excellence* at English seaside resorts. He laid stress on the importance of studying "individualism" in the selection of cases to be sent to marine climates. Also he was of opinion that residence at the seaside was most valuable in the treatment of patients who had passed some months in a sanatorium, and in whom permanent arrest had not yet been obtained. Several months were necessary before arrest could be procured, and the many attractions to be found at a seaside resort would be of great value in enabling patients to give the necessary time to the treatment without the weariness that necessarily ensues upon strict routine.

Dr. **Percy Lewis** (Folkestone) said that as long as there were consumption hospitals in congested areas, as the City Road and Brompton Road, London, it was necessary to convert the leaders of the profession to the imperative need for treating phthisis out of large cities. He criticised sanatoria treatment, and advocated the advantages of marine climates for the treatment of most forms of tuberculosis.

Dr. **Leonard Williams** said that sanatoria were doing a fine work not so much in curing phthisis as in educating the public in open-air methods. Marine climates could offer no such advantages, because climate without method was useless.

Dr. **St. Clair Thomson** spoke in emphatic terms of the necessity of instruction concerning the open-air methods carried out in inland sanatoria.

Dr. **Tyson** (Folkestone) spoke in favour of marine climates in the treatment of tuberculosis.

ULSTER MEDICAL SOCIETY.

Meeting held Thursday, April 4th, in the Medical Institute, Belfast.

The President, Dr. D. P. **Gaussen**, in the Chair.

Dr. H. L. **McKisack** showed a case of Aortic Stenosis in a child.

Mr. A. B. **Mitchell** read a paper, entitled "Suggestions as to Treatment of some Common Surgical Ailments, from a General Practitioner's Standpoint. The first ailment with which he dealt was the common and troublesome one of nocturnal seminal emissions. In this affection he recommended the use of counter-irritation over the lumbar region of the spine. The form in which he applied it was to blister an area about 3ins. by 2ins., remove the skin, and keep the sore open by the old-fashioned but most useful D'Albyspierre's paper. The same line of treatment he had recently tried in enuresis in children, and though too soon to say decidedly, he believed it promised well. The second ailment with which Mr. Mitchell dealt was the very common and important one of piles. Many patients would not submit to operation, and in cases of internal piles, he advocated treatment by injection, with certain strict precautions. A purgative should be given the night before, and an enema the morning of treatment. The patient was directed to strain down, and a pile being washed with boric lotion, was pierced at its base with a hypodermic syringe, going nearly but not quite through it. Into it is then injected from 3 to 10 minims (generally about 5) of a mixture of equal parts of hazeline and glycerine, with 10 per cent. of carbolic acid added. The needle is withdrawn very slowly, and the patient kept quiet for a few minutes before he goes to his ordinary occupations. If too great a quantity is injected the pile sloughs, but if it is done right it only swells up for a few days, and then disappears. At the first sitting only one should be done, and in a week or so, if the first is well borne, two may be done. Any ulceration about the pile renders it unsuitable for this treatment, and external piles are not suitable. Anal Ulcer and Anal Fissure need not always be operated on. After the free use of orthoform as a local anæsthetic pure ichthyol should be applied on a probe with cotton wool. This treatment is generally successful in two or three applications. In Pruritis Ani and Vulvæ, a saturated solution of chlorotone may be applied on wool, and is often successful. Chronic Abscess was dealt with by Mr. Mitchell at some length. There was no doubt that it was always tubercular, but the pus only contained dead bacilli, the living ones being found in the limiting membrane, wrongly called the pyogenic membrane. Some men advised one to let such abscesses alone in the hope that they might be absorbed, but he could only say he had never seen such a happy issue. On no account should they be simply opened and drained, for though the early results might seem good, soon there would be a mixed infection, temperature would rise, and endless trouble begin. Aspiration might be tried, and was often good if aseptic, but it frequently ended in infection of the skin, and was unlikely to cure. If it was done, he advised the subsequent injection of iodoform emulsion, which could be used with safety after careful boiling, up to 2ozs. being injected. The plan which he himself preferred was to open the abscess freely under strict aseptic precautions, and scrape it out with a flushing curette and boiled water. He did not drain, but merely loosened a stitch the day after to allow any fluid to escape. Tubercular Fistula or Sinus was often very troublesome. He had found far the most efficacious means of dealing with either of these was to inject 2 per cent. formaline into it. It was not a good treatment in a septic sinus, but most successful in tubercular ones.

The paper was criticised by Drs. Henry O'Neill, Fullerton, Calwell, and the President.

CEREBRO-SPINAL MENINGITIS AND PREGNANCY.

Dr. J D. **Williamson** read notes of a case of cerebro-spinal meningitis occurring in a young girl admitted to the Ulster Hospital for Children and Women for Labour. The patient was exactly thirteen years and nine months old, had never menstruated, and would not acknowledge her condition. She was taken ill in the early morning hours of March 5th, and was seen by two doctors, who agreed as to her condition, and sent her into hospital, where she arrived at noon. She then complained of violent abdominal pain, and vomited a little. Temperature was 101°. She was quite conscious. The os was only slightly dilated, and she seemed too ill for labour. Dr. Williamson was sent for, and on arrival at 2 o'clock, found her very ill, but still conscious. Her legs were flexed on her abdomen, and her arms on her chest, and dark spots had appeared on the skin of the abdomen, where none had been seen two hours before. She died at 4 p.m. and at a post-mortem examination a full-term male child was found in the uterus, and signs of cerebro-spinal meningitis in the brain and other organs.

THE THERAPEUTICAL SOCIETY.

Meeting held March 26th, 1907.

Prof. Nestor Tirard discoursed on the

TREATMENT WITH OPIUM IN PNEUMONIA.

He quoted Osler's and other recent text-books which prescribed opium. But in his own practice he never used opium nor morphine, unless after the crisis. In the albuminuria which occurs sometimes it would be harmful. If given for diarrhœa, is that not due to prescribing ipecac. ?

Dr. **French** suggested that the cause of albuminuria was probably blistering.

Dr. **Soper** was in the habit of giving opium and carbonate of ammonia. (He did not say if together and in what form). Also turpentine fomentations. On the whole the members present seemed to disapprove of opium as a routine treatment. Whether opium acts by way of depressing the heart's action was disputed, but it was considered better practice to administer strophanthus 5 m. twice a day from the commencement.

Prof. Dixon then read a highly scientific paper on

HOW DRUGS PRODUCE THEIR EFFECTS.

Carbon and bismuth, he remarked, act mechanically; sodium chloride is absorbed, but sodium sulphate is not. Again, strychnine acts on the spinal cord only, and on no other tissue, but it does not combine with any substance as one chemical with another. Pilocarpine stimulates vagus; so does electrode. They produce a sort of ferment in the terminations of the vagus within the heart muscle and so act in the same way, stopping the heart-beat. Experiments, he said, were made on a cat, already dead. This is a suggested explanation of the specific action of drugs, but in the absence of a clear knowledge of the organic chemistry of ferments, his inferences appeared to be hypothetical.

FRANCE.

Paris, April 7th, 1907.

Hæmorrhage in Disease.

Two varieties of hæmorrhage are obtained in infectious maladies: (1) Hæmorrhage of local origin due to intensity of congestion or lesions of the blood-vessels; (2) hæmorrhage from general causes, the result of modification of the humours of the organism. The latter, when slight, is not very serious, but when it becomes repeated and abundant it has the characters of the hæmorrhagic form of infection and is always grave.

M. Roger has studied the causes and treatment of these forms of hæmorrhage in an excellent article of which the following is a *resume* :—

Hæmorrhage from local cause results from several pathological conditions: (1) A particularly intense inflammation may end in rupture of the vessels. This hæmorrhage is generally benign; frequently petechae are observed on the legs in scarlatina; in small-pox, pustules of the legs and hands may be filled with blood, but do not indicate gravity. The same may be said of the mucous membranes; in cases of tonsillitis a sanguinous patch may be observed on the tonsil, in coryza there is frequently slight hæmorrhage from the nose (epistaxis), and blood-spitting may occur in laryngitis or bronchitis, vomiting of blood in gastritis, while slightly tinted stools may be observed at the outset of typhoid fever. Effusion of blood in the parenchyma producing infarctus of the lungs as in broncho-pneumonia, which sometimes passes unperceived and at others cause blood stained expectoration. Hæmaturia is frequently the first sign of nephritis, and is due to the intensity of congestion of the kidney. It is especially observed in those forms observed in scarlatina, pneumonia, or erysipelas.

(2) A certain predisposition favours the appearance of hæmorrhage. Thus persons with varicose veins present ecchymosis of the lower limbs in the course of eruptive fevers and in children suffering from whooping-cough, who contract measles, the rash assumes an ecchymotic aspect.

(3) The extension of the infectious disease provokes abundant hæmorrhage and if a thrombus has not had the time to form, death may result, as in the case of intestinal hæmorrhage of typhoid fever.

Hæmorrhage from general causes is due to divers causes. It can represent an ordinary symptom of infection as in purpura hæmorrhagica. It may result from a lesion of an organ playing an important *role* in the coagulability of the blood—the grave forms of icterus, or splenic disease.

It can also be the consequence of the virulence of the germ which produces the infection, as in the hæmorrhagic form of scarlatina and measles, typhoid fever, and, above all, small-pox, which is the most frequent.

As to treatment, absolute rest and immobility are indicated, as the slightest effort, movement, cough, or colic, may detach the clot and renew the hæmorrhage. Consequently baths should be suspended in typhoid cases and anodynes in the form of opium or chloral administered.

The general treatment should aim at modifying the coagulability of the blood and in these last years two new agents have been employed to this effect—

chloride of calcium, as recommended by Wright and Carnot, and gelatine.

Chloride of calcium is particularly effective in hæmorrhage of the digestive tract. A drachm a day is the proper dose.

Chloride of calcium, 1 dr.
Cognac, 1 oz.
Tincture of cinnamon, 1 dr.
Syrup of orange, 2 oz.
Water, 2 ozs.

A tablespoonful every two hours.

Oxygen water (12 vol) applied to the bleeding surface acts very well but is rather painful.

Carnot proved the advantages of applications of a solution of gelatine to increase the coagulability of the blood. The solution might be at 10 per cent., to which a few drops of formol are added, and finally sterilised by a quarter of an hour's boiling.

When the hæmorrhage is arrested, subcutaneous injections of artificial serum should be made to increase the tonicity and volume of the blood.

LOCAL PRURITUS (ANI, VULVA, &C).

Bromide of potassium, 30 gr.
Supulin, 30 gr.
Calomel, 30 gr.
Olive oil, 5 dr.

BLEPHARITIS.

Icthyol, 10 gr.
Sulph. of copper, 10 gr.
Vaseline, 6 dr.

GERMANY.

Berlin, April 7th, 1907.

TRANSMISSION OF SPIROCHÆTE FROM THE MOTHER TO THE CHILD.

THE *Deutsche Med. Zeitung* No. 19, '07, relates a case in which this took place. In a case of triplets one fœtus (male) was macerated. One child lived a few hours, whilst the third (a female) lived a day. The writer of the article, Dr. Wersilowa, was of opinion that all three fœtuses had reached full term. Far advanced syphilitic changes were present in the two first children. The palms of the hands and soles of the feet, as well as other parts of the body, showed papules. The second child, in addition to the above, had a large hard spleen, while the female child showed no morbid changes. The placenta, which was common, consisted of three parts, and was full of nodules in size from that of a pin's head to a pea. Nothing abnormal was seen about the umbilicus. The mother was syphilitic. Spirochætes were found in the expressed juices of the umbilicus, of the placenta, in section of the heart of the macerated child, in the papules, in section from the placenta, umbilicus, heart, lungs, spleen, the plaques and papules of the second child and spirochætes were therefore found in the placenta and umbilicus and in the organs of the fœtus even when the mother showed no signs of syphilis. He finished up by formulating certain conclusions. (1) The spirochæta pallida is present in syphilitic processes, also in the organs of new born infants affected with hereditary syphilis. (2) The spirochæta pallida may be transmitted from the mother through the placenta and umbilical evil. (3) The presence in the placenta, cord and organs of the fœtus is possible even when the mother shows no sign of the disease.

In eighty cases of hereditary syphilis in the new born the spirochæta pallida had been found in fifty of the number.

At the Fren Vererinyung der Cheringen Berlins, Hr. Israel reports

THE LATER RESULTS OF HIS 94 NEPHRECTOMIES FOR TUBERCULOSIS.

Of 3 patients nothing was known, 21 were dead, 11 as a result of operation, 10 died some years later. In 70 of the living the operation had been performed 5 to 15 years in 15 of them. Those cases had not been taken into account in whom the operation had been done less than one year. The information had been obtained by himself personally wherever possible, where this was not so some other medical man had reported. The following points were to be specially noted:—(*a*) The influence of the operation was almost always favourable as regarded increase in weight, 47 patients had increased in weight (10 to 90 lbs.), 2 patients had maintained their weight, 1 had lost through pulmonary tuberculosis. (*b*) The strength had become better in almost all cases. Disturbances of micturition were common in patients with tuberculous kidneys; they were present even when the bladder was normal, and removal of the kidney relieved the bladder symptoms. On the other hand removal of a tuberculous kidney effected also an improvement in a bladder already affected with the disease. In detail, as regarded bladder troubles, 31 per cent. were free from them before operation; after it 20 per cent. still had slight bladder troubles. Frequency of micturition was normal only in 15 per cent. before operation; but it became so in 60 per cent. after operation. In two patients with bilateral tuberculosis of the kidney there was no improvement, and in 2 others it got worse. A study of the influence of the operation on tuberculosis of the bladder showed that no patient who was free from it before operation acquired it after. The recovery of tuberculous bladders was ascertained partly by the cystoscope, and partly from proof of the gradual disappearance of the tubercle bacilli from the urine. Forty cases were tested in the latter way, 34 microscopically and 6 by animal experiment, and bacilli were found only in 3 cases. Functional improvement with bladder symptoms progressed only very slowly, rapidity being proportionate to the slight degree of the disease. All this was in favour of anatomical healing. These results followed even when the bladder was subjected to the after-treatment. In many cases, however, the functional bladder disturbance persisted even when the bladder and urine were normal. In such cases the bladder had become accustomed to frequent emptying, in many cases it depended on physical causes, as when the patient had previously suffered agonies.

He distinguished 3 stages of bladder disease—(*a*) disease in the region of the mouth of the corresponding ureter; (*b*) of the corresponding half of the bladder; (*c*) different disease. Class *a* ended in normal function in 75 per cent., slight disturbance in 16.6 per cent., serious disturbance in 8.3 per cent. Class *b* ended in normal function 66 per cent., slight disturbance 16.6 per cent., serious disturbance 16.6 per cent. Class *c* normal function 37.5 per cent., slight disturbance 10.5 per cent., serious disturbance 57 per cent. The more extensive the tuberculosis of the bladder, the less was it amenable to treatment.

Regarding the remaining kidney it was ascertained that more became tuberculous unless they were diseased before the operation. In one case non-tuberculous ascending pyelonephritis took place eight years after the operation. Pregnancy was not influenced by it. Of 8 pregnant women, 6 had normal labours at term, 2 had abortion that took place without disturbance on the side of the kidney; 65 per cent. of the cases had been saved by early operation. Early treatment was urgently called for. Experience taught that nearly all tuberculous diseases of the urinary tract proceeded from the kidneys, and they were never recorded spontaneously. The permanent results of nephrectomy were an encouragement to early operation, and the more frequently it was performed, the more would the mortality of the operation diminish.

AUSTRIA.

Vienna, April 7th, 1907.

PSEUDO-HERMAPHRODITES.

HAIM showed to the Gesellschaft two sisters, the eldest, æt. 20, with masculine habits. The first striking features were the voice and throat, the small developed breasts and the hair covering of the body. The genitals had a large unperforated clitoris with elongated prepuce while the index finger could be inserted into a narrow *cul-de-sac*; uterus and ovaries could not be discovered by the vagina. In the vulva oval swellings like hazel nuts represented the testes. They had been brought up as females, but have no sexual feelings.

Multiple Epiphysal Separation.

Hochsinger exhibited to the members a child four weeks old with loose epiphyses, the result of syphilitic osteo-chondritis. Shortly after birth the child ceased to move its limbs, particularly the arms, which seemed to have no power in them. Shortly after this a thickening around the joints commenced.

The child was of premature birth and had four large bullæ on the soles of the feet when born. The father had syphilis thirteen years before the birth of the child but the mother had no trace of the disease before marriage.

The swelling around the joints of the long bones was very painful and tender, with a hollow line above and below the joint in the soft tissue covering the bone, but the skin only was movable over the part. The most notable condition was observable in the upper third of the left femur where it was circular. The upper extremities were quite paralysed at first, but when pricked with a needle or the soft parts nipped, a distinct reflex action could be produced. When exhibited the child could again move its arms and slightly the legs. Passive movement in pronation and abduction also gave pain. The joints were still a good deal deformed and swollen.

The case seems to have been one of congenital syphilis having first Wegner's osteo-chondritis followed by epiphysal separation in the long bones. The Röntgen rays showed a space at the epiphyses and diaphyses. The diaphysial shadow had a shaggy network towards the epiphysis, clearly proving that the lime was irregularly distributed over the bones. The fractured ends appear to have been due to this granulation metamorphosis. The anti-syphilitic treatment has been adopted and appears to be successful so far.

Rontgen Ray Ulcers.

Lang presented a patient, æt. 30, who had been treated in Genoa with the Röntgen rays for malaria in the spring of last year. The rays had been liberally applied to the spleen and with such success that the patient came to his clinic in the month of September last year with a painful X ray ulcer 10½ by 7 centimetres broad. The pain was so extreme that he could not get sleep by day or night, no matter how large the dose of morphia.

Lang resolved to excise and cut out a large portion of the pectoralis major, serratus, and magnus intercostals, covering the raw surface after the Thiersch method in the hope of bringing about a healing condition. Immediately after the operation, the necrosis went on for a time, but now the healing seems to have commenced.

He next recorded the history of a few other cases which had come under his treatment after the Röntgen Therapy, as well as a few that have become ulcerated after the diagnostic application.

A young man, æt. 24, of a psychopathic nature, swallowed a few rusty nails, which required the rays to determine their position. Twelve days after the application a reaction in the skin took place over the site of the rays, and sixteen days later a necrotic ulcer commenced to form over the part where the rays had been applied. He was retained in the medical wards for a year, but the ulcer would not heal. At the end of this period the case was handed over to him to treat it as a surgical case, which he did by excising the ulcer entirely and immediately commencing the plastic operation with the best results. Lang thinks that as soon as it is discovered or suspected the part will ulcerate after the application of the rays, the part should be excised and plastic operations commenced to arrest the degenerative changes that are sure to follow.

Hepatic Cirrhosis.

Gruner recorded the history of a young girl who suffered from cirrhosis and large spleen. One day a varicose ulcer in the lower part of the œsophagus burst and died in thirty hours after from hæmatemesis. The *post-mortem* confirmed the diagnosis. The girl had been in the habit of taking a quarter of a litre of beer daily.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

THE ALLEGED INCREASE OF INSANITY.

In his annual report, Dr. Easterbrook, Medical Superintendent of the Ayr District Asylum, discusses the alleged increase of insanity, and takes a hopeful view of the facts. The Central Lunacy Authorities, who are in the best position to know, state that the number of persons placed on the register of the insane for the first time in their lives is year by year not increasing to a greater extent than can be accounted for by the increase of the population, which indicates that there is no undue increase in the absolutely new insanity of the country. At the same time the actual number of registered insane has for many years back increased to a greater extent than the population—some 1,858 of the population of Scotland has risen by 56 per cent.; but the number of officially known lunatics has risen 200 per cent. This increase is partially, but not wholly, ascribable to the accumulation of unrecovered lunacy, but there are, in addition a number of unrecovered lunatics who do not come under the cognisance of the general Board. It is not possible by the present method of annual lunacy statistics to arrive at the total picture of mental unsoundness in this country; the nearest approach to the truth could be reached only by retaining all certified persons on the general register until they recovered or died, which would entail a system of notification somewhat similar to the notification of infectious disease. Notwithstanding the apparently gloomy picture of the gradual increase of the total lunacy of the country, the last Blue Book contains the comforting news that during 1903, 1904 and 1905, there were signs of retardation or even of arrest, and in 1905, for the first time, there was no increase on insanity relatively to the population. The receptions into the asylums in 1906, in every case without exception, presented distinct evidence of the possession of a neurotic or neuro-insane constitution, which in Dr. Easterbrook's experience is the essential etiological basis of insanity in the individual. Enquiry into the antecedent history of the patients—temperament, habits, early manifestation of nervous or mental symptoms, minor congenital defects, physical signs of degeneracy (which, however, should be judged of cautiously, since isolated stigmata occur in normal capable persons) or heredity, showed that in no instance could these be excluded, prior to the outbreak of insanity, the existence of a morbidly reacting brain, or bad heredity, faulty modes of life, or previous disease.

Dr. Easterbrook emphasises the importance of recognising and admitting the danger of peculiarities of temperament as a soil on which insanity is prone to develop, and by careful nurture and education of such persons, by attention to the laws of health in later years, and by avoidance of undue stresses, avoiding the breakdown which will ensue if they live like their normal fellow men. All other or "exciting" factors of insanity operate solely on neurotic individuals. Among such was worry, anxiety, overwork, alcoholism, and periods of physiological stress. Another group of patients suffered from general paralysis, and finally the third group was that in which insanity was due to toxæmia. There is much loose talk, at present based on one-sided and insufficient evidence, on the toxic causation of insanity. Poisoning of the nervous system arising from disease or bad habits is an important factor, but only one of many, and lights up insanity only in a predisposed person, not in the absence of the neuro insane diathesis. Take the case of one of the patients who became insane while convalescing from pneumonia, a small slightly built woman, subject for years to migrane, excitable, the daughter of a neurotic man, the sister of a neurotic brother, was not her constitution a more important factor in producing insanity than the pneumonia? Yet the toxic school assert that not only may pneumonia "cause" insanity, but that insanity may be "cured" by an attack of some acute infection. The mere fact that a fever may be but harmful and beneficial, suggests that the insanity is mainly dependent on some other factor.

Take again the cases of alcoholic insanity who form the bulk of the toxic group (12.7 per cent. of the admissions), all presented distinct evidence of the neurotic constitution. Is it not well recognised that many persons can consume vast quantities of alcohol without their nervous systems breaking down. Those who attribute to the elusive factor of toxæmia an all important influence in causing insanity are deliberately shutting their eyes to signs which "he who runs may read."

BELFAST.

Public Health.—The new Fever Hospital at Purdysburn is not long in coming into full use as appears from the report of the medical officer of health for the past month. It appears that 302 cases of infectious disease were notified, including 104 cerebro-spinal meningitis, 89 typhoid and simple continued fever, 58 scarlet fever, 27 diphtheria, and 4 puerperal fever. During the past week the daily number of cases of cerebro-spinal meningitis has not been published, as the Public Health Committee has come to the conclusion that constant bulletins only alarm the public, but as far as can be ascertained there have been only a moderate number of new cases, and no signs of an increase in the epidemic. There are now 40 cases under treatment at Purdysburn, the total number notified up to date being 261, with 136 deaths. During the week ending Saturday, the 30th ult., there were 31 fresh cases.

LETTERS TO THE EDITOR.

RAYNER'S REPRIEVE AND THE PLEA OF INSANITY.

To the Editor of The Medical Press and Circular.

Sir,—Although your correspondent "M.D.,D.P.H.," has been gratified with innumerable others at the reprieve in question, which, as you remark, probably represents the sentiment of the great majority of the medical profession, it is interesting to note that the lay press has been all but, if not unanimous, in strongly condemning the Home Office for yielding to what it pleases to regard as a hysterical outburst of public feeling. This notwithstanding that about half a million of the British public were about to petition the Home Secretary for the reprieve, of which he no doubt had knowledge, and could not, advisedly, turn a deaf ear. On the other hand there is no evidence, I think, to show the writers of the articles in the daily press for the reprieve, represent any considerable section of the public against the reprieve.

There is, I imagine, ample evidence that the condemned man in mind was greatly perturbed and unhinged, suffering from a grievance either real or imaginary, that he was "the illegitimate outcast" of his victim. Further that he was seized with the idea that natural parentage afforded him a strong moral claim in his dire poverty and distress to seek succour out of the abundance which his victim apparently possessed. Although the case has been represented as one of common blackmail, the fact remains that it culminated in homicide, with a determined, yet abortive, attempt at suicide.

Undoubtedly a case of this kind without positive evidence of insane delusion is of great difficulty and delicacy. It is one upon which neither the jurist nor the alienist can afford to dogmatise. We cannot escape the fact that the whole criminal code with its penalties is pivoted and founded on the hypothesis that so-called free will and moral responsibility does to some degree exist. On the other hand the idea of non-freedom of will, although as old as the hills, seems to be gaining in currency nowadays. Possibly the general spread of education which tempts many to dip beneath the surface and think for themselves, accounts for the spread of these ideas. Meanwhile, those who believe in absolute non-freedom of will—in other words, that we are mere organic machines in the universe—may take courage in the thought that the human race has improved and hope the evolutionary processes or machinery may eventually turn out a purer, healthier, and better race than that hitherto produced.—I am, Sir, yours truly,

Clement H. Sers.

Brighton, April 5th, 1907.

THE ANTI-VACCINATION CHAMPION.

To the Editor of The Medical Press and Circular.

Sir,—Mr. Lupton, who holds the proud position of champion of the cult of anti-vaccination in the House of Commons, seems likely to meet the fate of a former member, who, to the frequent amusement of the House, held up alone the banner of "No Popery" for many years. This gentleman discovered the hands of the Jesuits in every political movement, and brought in the end such ridicule upon his attitude that he was once seriously charged with being himself a Jesuit in disguise entrusted with the task of damaging the cause he was ostensibly fighting for. Since I called attention to Mr. Lupton's oration last month he has delivered another of similar length and character, this, like the former, being greeted throughout with continuous laughter. The following excerpt will show that the mirth was well provoked.

Mr. Lupton said "that the carcases of cows from which lymph for the purpose of vaccination had been extracted were sold in the markets. The consumption of this diseased meat led to that physical degeneration among the people which swelled the ranks of the unemployed. The matter taken from the calf contained the germs of cancer and other diseases. This was admitted by medical men, who also said that the organisms might be destroyed by mixture with glycerine. Used as food, were the animals from which the poisonous stuff was taken likely to benefit the health of the people? In consequence of vaccination enforced under the law infants had sickened and died. He mentioned several cases, and exhibited a photograph, regretting that he could not display a screen picture of the horrible sores. There had been Local Government Board reports, but these were kept secret, and from that they could draw their own inferences."

That such fatuous drivel should meet with the ridicule which alone it merits in the House is so far satisfactory, and there need be no doubt anti-vaccination is getting nothing but harm in Parliament from Mr. Lupton's advocacy. I should like to ask once more, what can be the mental calibre of the body of people whom he represents, what respect do their outcries deserve from the Legislature of a civilised State? They are on a level with children and can be safely dealt with only as such.

I am, Sir, yours truly,

Onlooker.

Bradford, March 30th, 1907.

THE ALCOHOL QUESTION.

To the Editor of The Medical Press and Circular.

Sir,—I have before me your leader on Temperance and Legislation of January 23rd, 1901. This leader concludes in the following sentences: "Let them distinguish clearly between alcohol, the distilled product of fermentation, and those more necessary fluids which are obtained by fermentation of the juice of the grape, or the infusions of various grains, in which the small amount of alcohol produced by fermentation plays a very small part in their value as articles of diet. If legislation comes up for consideration, let it be clearly pointed out that alcohol distilled and separated from any fermented solution is quite a different thing from fluids which are simply obtained from natural and wholesome sources, and have gone through the most strange and important change which fermentation produces in them, and renders them of such great value as articles of diet."

It would be well for those who are interested in the alcohol question to consider carefully what is contained in your leader. I see that Mr. Tomlinson, in his letter to *The Times* (April 2nd, 1907) on Dr. Dawson Burns and the Drink Bill, remarks that Dr. Burns' figures "convey the impression that alcohol is made out of air or some equally inexpensive article"; and the fact that Faraday and Hennell, in 1820, obtained traces of alcohol by passing olefiant gas (bicarburetted hydrogen) through sulphuric acid certainly leads one to the conclusion that we must not treat fermentation as a chemical process for making alcohol, and nothing more. "Herodotus ascribes the first discovery of the art of brewing barley-wine to Isis, the wife of Osiris, and a beverage of this kind is mentioned by Xenophon 401 B.C." (Haydn's Dict. Dates.)

As the leading medical journals do not seem to have treated this subject as you did in your leader, it would be well for them to try and clear away on sound scientific grounds the differences that exist in the profession on the various questions that have to be considered before reasonable and sound legislation can be expected.

I am, Sir, yours truly,
Temperance.

Pwllheli, North Wales, April 3rd.

THE SUPPRESSION OF FRAUDULENT ADVERTISEMENTS.

To the Editor of The Medical Press and Circular.

Sir,—Knowing the interest taken by The Medical Press and Circular in the suppression of fraudulent advertisements, I make no apology for calling your attention to the impudent attempt which is being made by a certain firm to foist a worthless disinfectant preparation on the consumer by means of a chemical trick.

In the enclosed advertisement, the manufacturers in question offer facilities for demonstrating their "claim." Their preparation is, of course, provided with a taking name. On analysis it is found to be nothing more or less than a weak solution of chloride of zinc. You will see from the enclosed test form that even pure chloride of zinc is, at best, a feeble disinfectant; indeed, this particular solution has a carbolic co-efficient of 0.02 when tested by Dr. Rideal's method, and is absolutely useless for the purposes for which it is sold.

Of course, a very elementary knowledge of chemistry, which the public do not unfortunately possess, is sufficient to explain the reaction which takes place when carbonate of ammonia (the particular form of ammonia employed by these people in their test in the advertisement) is added to a solution of chloride of zinc; and the public are thus artfully led to believe that this worthless "new disinfectant" must be a powerful deodorant and antiseptic for general use.

I am, Sir, yours truly,
Analyst.

THE ELIMINATION OF THE UNFIT.

To the Editor of The Medical Press and Circular.

Sir,—To palliate a symptom when the cause cannot be got at is often justifiable; it is sometimes pardonable to mistake a symptom for the disease, but it can never be excusable deliberately to treat a symptom when the causes of the malady are known and can be prevented or removed. Nothing can be more certain than that the existence of a large percentage of the unfit among the populations of civilised states is merely a symptom of diseases in the body politic, the main causes of which are well understood, and it is evidently out of the question to suppose that the legislature of any enlightened people will attempt to deal with that symptom by drastic measures until an attempt shall have been made to get at the *fons et origo mali*. The fact that science has for the first time given mankind the power to mould as they please their physical and even their moral future is slowly sinking into the minds of statesmen and gradual progress is already being made, and when the nations rouse themselves and put their social and sanitary institutions on a level with science, a great part of the evils now existing will be speedily put an end to. Malnutrition, rickets, syphilis, typhoid fever, tuberculosis, alcoholism, poverty, filth, bad housing, ignorance and cruelty of parents, all these are causes of degeneration; many of them are in constant action together. How many children are made unfit by the criminal neglect and cruelty of parents. The fact that the Society for the Prevention of Cruelty to Children prosecutes successfully in many thousands of cases annually is sufficiently suggestive of the extent to which the ranks of the unfit may be swelled by this cause alone. It would be interesting if Dr. Rentoul, whose book is reviewed in your paper this week, would some day discuss this question from the point of view in which I have attempted to place it.

I am, Sir, yours truly,
April 4th, 1907. A Student of Sociology.

LONDON AND ITS MILK SUPPLY.

To the Editor of The Medical Press and Circular.

Sir,—In the leading article on this subject in the current number of the Medical Press there occurs the following sentence:—"It seems probable, in the light of the evidence obtained" (by the investigations of the Royal Commission on Tuberculosis), "that the major part of the terrible sum total of infantile tuberculosis, and possibly a fair proportion of the disease in adults, arises from milk infection."

In view of such a strong statement, I shall be much obliged if the writer will be good enough to refer me to one solitary case in which there was even a probability—not to say evidence—that this disease had been communicated by means of milk.—I am, Sir, yours truly,
Geo. Granville Bantock.

14, Upper Hamilton Terrace, London.
April 6th, 1907.

[Our correspondent speaks of "a strong statement," but appears to have overlooked the careful qualifying introduction. "It seems probable that." It is now proved scientifically that "live" tubercle bacilli can be conveyed in milk. If milk thus infected be swallowed by children, there is a reasonable certainty that by the law of averages cases of tuberculosis must result. As a scientific man, Dr. Bantock must be well aware of the extreme difficulty that attends the positive identification of the agency of the conveyance of specific zymotic infection in many cases.—Ed. M.P.& C.]

OBITUARY.

ANDREW SCOTT MYRTLE, M.D.Edin., J.P.

By the death of Dr. Andrew Scott Myrtle, Harrogate has lost one of its oldest and most respected citizens. For nearly fifty years he formed a leading figure in the life of the town, and his death at the ripe age of 82 has left behind a widespread sense of personal and of civic loss. In 1839 he was apprenticed for five years to his brother, an Edinburgh physician. In 1844 he took the degree of Doctor of Medicine of Edinburgh University, as well as the licentiateship of the Royal College of Surgeons. In 1847, after two years spent in locum tenens work, he returned to Edinburgh, where an epidemic of typhus fever was raging; in the combating of this outbreak he worked assiduously until he contracted the disease. For some years he conducted a large practice at Polmont, in Scotland, but ultimately he settled in Harrogate. Here he was a pioneer in bringing the virtues of the Spa waters before the public. Among various books on this subject the best known is "Chronic Diseases at Harrogate Spa," published in 1876. Another in 1887, "Practical Observations on the Harrogate

Mineral Waters," written in conjunction with his son, Dr. T. A. Myrtle, is now in its fourth edition. Deceased for many years held the position of a county magistrate, and was a prominent member of many official and social undertakings connected with Harrogate. He was also a voluminous writer, and made many contributions to current medical literature, of which perhaps the best known are those relating to the Harrogate waters. He leaves a widow, a daughter, and three sons, one of whom, Dr. George Myrtle, will carry on the practice which has so largely contributed to the name and fame of Harrogate.

THOMAS HENRY WAKLEY, F.R.C.S.ENG.

WE regret to announce the death of Thomas Henry Wakley, the senior proprietor and editor of *The Lancet*. Mr. Thomas Wakley passed the eighty-sixth anniversary of his birthday a few days before he died. He was the eldest of the three sons of Thomas Wakley, the well-known coroner and Member of Parliament, who founded *The Lancet* and brought about an era in medical reform. Mr. Thomas Wakley was educated with the intention that he should enter the Church. He entered as an undergraduate at Oxford, but his connection with the University was brief. His father's radical opinions were not acceptable at Oxford, where Wakley found his political and social creed regarded as very like high treason. To the University of London Thomas Wakley then went, and entered the medical department of University College. In the year 1845 he took the diploma of Membership of the Royal College of Surgeons of England, having previously studied also at Paris because of his father's views that the scheme of medical education enjoyed by the Parisian students was preferable to that of the London medical schools.

In the year 1848 he was elected assistant surgeon to the Royal Free Hospital, a hospital which was started in 1828 in a building at Hatton Garden as a protest against the system of letters by which the subscribers to the medical charities of London were able to dispense patronage upon exclusive principles. This hospital made a great stride forward in 1842 when it was removed to its present site, and the appointment formed an admirable opening for young Wakley, who entered into his duties with great enthusiasm. At the end of the next year he passed the Fellowship exam. of the Royal College of Surgeons, and weathered successfully a blackmailing action for malpraxis brought against him by a hospital patient.

Shortly after this, Wakley, whose position as an operating surgeon was now well established, moved to No. 7, Arlington Street, where he enjoyed for many years a good surgical practice, many of his patients belonging to the highest classes of society. While in Arlington Street Wakley made a special study of diseases of the urethra and invented an ingenious dilator which in his hands gave very good results. He was also the first to introduce the use of glycerine into practical surgery, and an article on the point, published in *The Lancet*, attracted considerable attention and incidentally gained for him some reputation as an aural surgeon, as it was in relation to the treatment of affections of the external auditory meatus that his experiments were made. He also wrote the article upon Diseases of the Joints in one of the later of the many editions of Samuel Cooper's famous "Surgical Dictionary."

In 1862 his father died and the editorial conduct of *The Lancet* passed to his brother, the late Dr. James Wakley, but Thomas Wakley as part proprietor of the paper was actively interested in its conduct. His life as an active surgeon was then combined with that of a journalist, but eventually he retired from consulting practice in 1882. He came daily to *The Lancet* office, and acquired such experience that he was able upon the death of his brother in 1886 to assume the editorship in association with his son. Under his guidance as senior editor *The Lancet* steadily kept its place as one of the leading medical journals of the English-speaking race, and maintained the high tone in medical ethics which its founder aimed at. Of enormous activity, physical and mental, Mr. Wakley was never ill and never absent from his duties. In all weather and on all occasions he arrived in the early morning at his office. During the last few years the editorial management of the journal passed more and more to the hands of the son, but to the end of his life Thomas Wakley showed no abatement of interest in the paper. During all the period in which he was associated with the editorship of *The Lancet* great attention was given to the work of the Hospital Sunday Fund, for the fund was largely founded by Dr. James Wakley, and Thomas Wakley desired that the interest manifested by his brother should not be allowed to flag. His sympathy with the welfare of the medical profession was shown by the institution of *The Lancet* Relief Fund, the income of which was supplied by himself and his son as the proprietors of *The Lancet*. He was also a warm supporter of Epsom College, and in 1902 he gave a donation of £1,000, and he was always ready to support the claims of the College upon medical practitioners. He was concerned in the ambulance department of the Order of St. John of Jerusalem and was Knight of Grace of that Order. His last illness was also his first, and took the form of repeated attacks of dyspnœa. He was ill only six weeks, and the end came quietly last week.

We may add for the information of those of our readers desirous of attending, that the funeral service will be in St. Mary Abbot's, Kensington, to-day (Wednesday) at 12.15.

LAURENCE W. K. PHILLIPS, M.D.DURH., M.R.C.S., L.R.C.P., D.P.H.

WE regret to record the death of Dr. L. W. K. Phillips, of Hove. Dr. Phillips was educated at Guy's Hospital, and took the M.R.C.S. in 1880, the L.R.C.P. five years later, and the D.P.H. in 1884. He graduated M.D.Durham in 1898. He was well known at Hove, where he was surgeon to the police and honorary medical officer to the Hove Hospital and Dispensary. He enjoyed the confidence of a large circle of friends and patients, and his funeral was attended by many of his medical colleagues and representatives of many institutions with which he was connected.

HENRY REEKS, M.R.C.S., L.R.C.P.

WE regret to record the death of Dr. Henry Reeks of New Shoreham. Dr. Reeks studied at St. Bartholomew's Hospital, and took the qualifications of M.R.C.S. and L.R.C.P. in 1891. Settling in Shoreham soon afterwards he attained a quick popularity, and was elected medical officer to the infirmary and workhouse. He was also a member of the District Council. Dr. Reeks was a keen footballer and cricketer, and his early death has caused great regret amongst those who knew him.

COLIN M. CAMPBELL, L.R.C.P. AND S.EDIN.

WE regret to announce the death, under painful circumstances, of Dr. Colin Mansfield Campbell, of Winlaton. The deceased gentleman was apparently in his usual health on April 2nd, but between seven and eight o'clock on April 3rd his housekeeper found him lying ill in his room. The efforts of the medical men summoned were of no avail, the patient only lingering about two hours. Death is believed to have been due to an overdose of morphia. Dr. Campbell was a native of Tasmania, New South Wales. He studied at the University at Melbourne, Australia, and afterwards entered the Royal College of Surgeons, Edinburgh, taking the degrees of L.R.C.P. and L.R.C.S., Edinburgh, and L.F.P.S., Glasgow, and some four years ago he came to Tyneside. He was an enthusiastic footballer, and in taking up his residence at Winlaton he associated himself with the Vulcans Rugby Club. As a cricketer he also made a name for himself locally. He was, indeed, a batsman of great merit. Dr. Campbell's ability as a medical practitioner was recognised, and the news of his untimely end was received with sorrow and regret by the people of the Winlaton district, as it will be by footballers and cricketers throughout Northumberland and Durham, for among these he was very popular. Deceased was 35 years of age, and leaves a widow.

WILLIAM DAVID DAVIES.

THE death of Dr. William David Davies, Llantrisant, removes one of the oldest inhabitants of the district. Deceased was born in Newport nearly 80 years ago. At the age of about 28 he turned his attention to medicine. He qualified and went to Llantrisant, where he practised until the time of his death. He held the offices of medical officer to the Llantrisant and Llantwit Fardre Rural District Council, and also to the Llantrisant District of the Pontypridd Union until five or six years ago, when he resigned both positions in favour of his son. He leaves a widow and two sons and two daughters, his eldest son being Dr. Naunton Davies.

SPECIAL ARTICLE

THE UNIVERSITY QUESTION IN IRELAND

SEVERAL events of importance in the battle which is still waging on the University question have occurred during the past fortnight. On March 26th, the graduates of the University of Dublin met under the auspices of the Dublin University Defence Committee in the Hall of the Middle Temple for the purpose of considering the proposed withdrawal of the Charter of Trinity College, Dublin, and the University of Dublin, and their reconstitution as intended by the Government in the interests of the Roman Catholics in Ireland. The meeting was addressed at considerable length by Lord Rathmore, after which, on the motion of Sir Robert Ball, seconded by Professor Dowden, the following resolution was passed :—

"That this meeting protests against any legislation which would transform the University of Dublin into a University comprising Colleges identified with different religious denominations and animated by conflicting educational ideals, and further records its belief that such change would introduce sectarian division into the administration of the University and subject teaching and research to limitations injurious to liberal education and free enquiry. This protest is made, not on political grounds, but solely in the interests of liberal education."

During the past week, two important memorials have been placed in the hands of the Chief Secretary for Ireland. The first of these is from the "Principals, Professors, Former Professors, and Lecturers in the Scottish Universities," and is as follows :—

"We, Principals, Professors, Former Professors, and Lecturers in the Scottish Universities, actuated solely by academic reasons, and in no spirit of hostility to the Government, desire to bring under your notice our views in regard to the proposal to cancel the Charter of the University of Dublin, with the object of associating within it Trinity College and a number of other colleges of recent, or even future foundation. Hitherto the University of Dublin has been "one and indivisible," with Trinity College. During the three hundred years of its existence it has gathered around it noble traditions, and has rendered incalculable service to the State We would most respectfully submit that we regard with repugnance the proposal to sever the intimate and historic connection between the College and University, and to destroy the identity and independence of an Institution which has contributed so much in the past to the advance of knowledge and the spread of higher education, not only in Ireland, but throughout the Empire at large. We do not think that an ancient seat of learning, justly proud of its past and present usefulness, should be forced against its will into a federation which it believes would be destructive of its prestige and its efficiency. Apart from the considerations referred to above, we do not consider that a federation of widely separated colleges under the University of Dublin is a solution of the Irish University problem which is likely to achieve any measure of success. Experience has shown that even in cases where the federated Colleges are of similar age and origin, in near propinquity to each other, and animated by similar sentiments and aspirations, failure has attended such combinations. How much more is such a scheme likely to fail where, as in Ireland, the different elements it is proposed to unite are already discordant. This memorial is presented in no spirit of antagonism to reasonable claims of the Roman Catholics of Ireland in respect to University education. Our concern is entirely with the preservation of the University of Dublin and Trinity College, an institution which commands our admiration and respect."

Attached to the above memorial are the names of 199 professors, lecturers, and other officers of the Universities of Aberdeen, St. Andrews, Edinburgh, and Glasgow.

The second memorial is from the Principals, Professors, and Heads of Departments in the Constituent Colleges of the University of Wales. It is couched in very similar terms to that presented by the Scottish Universities, but is of greater length. It possesses a special interest of its own in that it represents the views of the staff of federated Colleges in Wales with regard to a proposed scheme for the federation of Colleges in Ireland.

On Saturday last, a letter appeared in the daily papers from the Secretaries of a Committee appointed to ascertain the opinions of the Roman Catholic laity in Ireland with regard to Mr. Bryce's scheme. The Committee sent out the following Declaration for signature :—

"That the Government's scheme of Irish University Reform, designed to secure educational equality for Catholics through the foundation and endowment of a great College in Dublin as a constituent College of a re-modelled Dublin University, merits our strongest support; and we affirm our conviction that to be in consonance with Catholic ideas, and acceptable to the Irish people, such new College must be granted (1) whatever faculties in Arts and Science, equipment, academic privilege, and public endowment any other constituent college of the common University may possess; and (2) the fullest possible measure of autonomy."

The Secretaries now announce that in the short time which has elapsed since the declaration was first offered for signature they have received over a thousand signatures. The *Freeman's Journal* devotes some twelve columns to the list of names, which include those of a large number of prominent Catholic laymen. On the other hand, we note the absence of a large number of equally prominent names.

On the same day that this list appeared, the *Irish Times* stated that "the Government has abandoned definitely the intention of introducing an Irish University Bill in the course of this Session of Parliament."

This very definite announcement was followed later in the day by an equally definite announcement made by Mr. Birrell to a deputation from the Province of Connaught to protest against the exclusion of Queen's College, Galway, from the proposed scheme. In his reply, Mr. Birrell referred to the announcement "that his Majesty's Government had abandoned the projected legislation for this University question," and continued:—"There is not a word of truth in that statement. There is no subject in which the Government takes a greater interest than in this, and our determination to deal with it at the earliest possible moment remains unaltered and unaffected. . . . . Therefore, we shall certainly proceed as quickly as we can to lay our proposal before Parliament."

MEDICAL NEWS IN BRIEF.

Lord Lister's Eighty-First Birthday.

On Thursday last a meeting, convened by the Lister Institute of Preventive Medicine, took place at the Royal College of Surgeons of England. Some short time ago a committee of some 200 members was formed with a view to celebrating in some suitable manner Lord Lister's 81st birthday, which event took place last Friday. This committee was representative of the medical and scientific leaders of Great Britain and of foreign countries, and it was interesting to note that Professor Tilanus, representing the profession in Holland, and Dr. Madsen, of the Danish Academy, were present at the meeting; thus two of the first countries to adopt antiseptic surgery were represented.

The President of the College of Surgeons, Mr. Henry Morris, was voted to the chair, and was supported by some 50 members of the committee, among whom were:—Sir Thomas Smith, Sir William Church, Mr. Jonathan Hutchinson, Sir Felix Semon, Sir Lauder Brunton, Dr. Ferrier, Surg.-Genl. Branfoot, Mr. Reginald Harrison, Professor William Osler of Oxford, Mr. Watson Cheyne, Mr. Rickman Godlee, Dr. Sims Woodhead of Cambridge, Mr. Henry T. Butlin, Colonel Bruce, Professor Keatinge of Cairo, Mr. Mayo Robson, and Dr. C. J. Martin, Director of the Lister Institute.

Dr. Martin made a few remarks as to the object of the meeting, and read the following telegram from the Pasteur Institute in Paris:—"On the occasion of the eightieth anniversary of Lord Lister, we beg you to present to the renovator of surgery the felicitations and the homage of his admirers of the Institut Pasteur." It was felt that, owing to Lord Lister's age, no festival or dinner could be held, but, as a mark of appreciation of his writings, it was decided to form an Editorial Committee to collect and publish them, which, when completed, are expected to occupy two volumes of about 500 pages each. To carry out this work the following were elected as the Editorial Committee:—Sir Hector Cameron, Mr. Watson Cheyne, Mr. Rickman Godlee, Dr. Dawson Williams, and Dr. C. J. Martin.

A small deputation, bearing the best wishes of the meeting, waited on Lord Lister on the following day and extended to him birthday greetings.

The Recent L.G.B. Vaccination in Ireland.

A joint deputation from the University of Dublin, the Royal College of Physicians, and the Royal College of Surgeons, waited on the Chief Secretary yesterday in connection with the Local Government Board's recent Vaccination Order, which they asked to have cancelled. The members of the deputation were as follows:—Dr. James Little, Regius Professor of Physic in the University of Dublin; Dr. Joseph Redmond, President Royal College of Physicians; Mr. Henry R. Swanzy, President Royal College of Surgeons; Mr. John Lentaigne, Vice-President, Royal College of Surgeons; Sir John W. Moore, F.R.C.P.; Dr. Andrew Horne, F.R.C.P.; Sir Arthur Chance, F.R.C.S.; Mr. Thomas Donnelly, F.R.C.S. Mr. Birrell, having heard the representations made by the deputation, undertook to give the matter his most serious attention.

Royal College of Surgeons in Ireland.

The following is the prize list of the Royal College of Surgeons in Ireland for the Winter Session, 1906-1907:—

Descriptive Anatomy.—Junior: J. T. Duncan, 1st prize; T. Dowzer, 2nd prize. Senior: H. G. P. Armitage, 1st prize; W. Swan, 2nd prize.

Practical Anatomy.—First year: T. M. Thomson, 1st prize; F. W. Warren, 2nd prize. Second year: W. Swan, 1st prize; H. G. P. Armitage, 2nd prize.

Practice of Medicine.—C. Green, 1st prize; G. S. Levis, 2nd prize.

Surgery.—G. S. Levis, 1st prize; W. R. Burton, 2nd prize.

Midwifery.—H. W. White, 1st prize; G. S. Levis, 2nd prize.

Physiology.—H. M'Adoo, 1st prize; O. G. Connell, 2nd prize.

Chemistry.—P. F. Crowe, 1st prize; J. T. Duncan, 2nd prize.

Pathology.—I. Scher, 1st prize; C. Greer, 2nd prize.

Physics.—J. T. Duncan, 1st prize; T. Buckley, 2nd prize.

The lectures and practical courses of the Summer Session commenced on Monday, April 8th.

Doctor Robbed.

At New Mills on April 3rd, Edwin Sharkett, 17, who had been arrested in Manchester, was charged with stealing a gold watch, value £40, the property of Dr. Frederick Ashurst, of Hayfield. The youth's mother is housekeeper to the doctor, and the watch was missed from the pocket of a waistcoat hanging in the hall, following a visit by the lad on February 13th. Robert Jones, travelling showman, Ancoats, stated that he agreed to buy the watch for ten shillings, Sharkett having told him he found it in a waistcoat on a hedge at Hayfield. He sold the watch the same day for £3. Questioned by the magistrates, Jones said he was in the habit of giving 1s. 5d. each for watches to give to those who "throwed" at his cocoa-nut stall, and he bought this watch for that purpose. Sharkett, who pleaded guilty, was sent to one month's hard labour, while Jones was advised to be very careful in future.

A child whose relatives reside in Old Cross Street, Tipton, has been certified by medical men to be suffering from spotted fever. Precautions have been taken to prevent the spread of the disease, the patient having been isolated and the house thoroughly disinfected.

Various forms of infectious diseases are prevalent in the King's Norton district, and it is probable that some of the infant schools will have to be closed for a further period at the expiration of the Easter holidays. The rapid increase in the number of cases led to the infant schools being closed a fortnight ago.

On April 2nd, the Metropolitan Asylums Board reported that a case of spotted fever had been admitted to the Eastern Hospital from Shoreditch.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for The Medical Press and Circular.

RECENT GYNÆCOLOGICAL AND OBSTETRICAL LITERATURE.

Forcible Dilatation of the Cervix Uteri, and Vaginal Caesarean Section are compared by Müller (*Zentralbl fur Gyn.*, 1907, Nr. 11). He shows that while both Bossi's method and the vaginal Cæsarean section of Dührssen are undoubtedly of value, that one method is more suitable for some cases than the other. Firstly, he says that Bossi's method requires less practise and operative skill than Dührssen's. The lacerations of the cervix, which are the most important complication of instrumental dilatation, may be prevented in the majority of cases. The danger of infection during the employment of Bossi's method is not serious, since it can also be prevented to a certain degree. When the cervix is very firm and rigid, the canal completely closed, and immediate delivery is indicated, for example, in eclampsia, Müller recommends the vaginal Cæsarean section. If the cervix is a little dilated, or soft, elastic, and dilatable, and the internal os is already partially obliterated, Bossi's method is the better, if at least thirty minutes can be spared for its employment. This, according to the writer, will be the suitable treatment for most cases of eclampsia, threatened rupture of the uterus, uterine inertia, placenta prævia, &c., and also for some cases of abortion. The author concludes that since no case is like another both methods have their strict indications to recommend them to the obstetrician. G.

A Case of Vagitus Uterinus is recorded by Stock (*Zentrallbl. fur Gyn.*, 1907, Nr. 11). He says he was called to a woman in labour because the child lay transversely. The membranes had ruptured two hours before, and there was prolapse of the right hand. At the moment when the writer was about to bring down a foot, he heard quite distinctly a short cry in the interior of the uterus. Version was easily performed, but the extraction which followed immediately was difficult. The child was born in a state of asphyxia, but was revived after ten minutes. It died when a year old of pneumonia. In the author's opinion every vagitus uterinus is due to disturbance of the placental circulation. G.

Laparotomy in Cases of Irreplacable Retroverted, and Retroflexed Gravia Uteri.—Küstner (*Monatssch fur Gebund Gyn.*, Bd. xxv. Hfh. 2) records the case of a primipara, æt. 23, whom he had treated a year previously for an incomplete abortion. She had then a fixed retroversio-flexio. She has now come for treatment again on account of ischuria paradoxa. Retroflexion of the gravid uterus was diagnosed. All attempts at replacement even under anæsthesia were unsuccessful. It was therefore decided to do a laparotomy. There was a large mass of thin adhesions binding the retroflected uterus, which was between four and five months pregnant, the ovaries, tubes, peritoneum of the rectum and of the posterior wall of the pelvis, together. After separation of these the uterus was brought into anteflexion and a Smith pessary inserted. The convalescence was uneventful. The pessary was removed when the patient was leaving the hospital. The uterus retained its position of anteflexion during the remainder of the pregnancy. The author maintains that in cases of incarceration of the gravid uterus, the treatment shall not be altogether confined to the protection of the urinary bladder, where possible by the induction of abortion. One should endeavour above all things to bring the uterus into its proper position, even through a laparotomy. There is nothing, he says, by which recovery of a severely injured bladder, as far as such is possible, is better or with more certainty promoted than by placing the uterus in its proper position. G.

Ruptured Extra-Uterine Pregnancy with free Hæmorrhage into the Peritoneal Cavity.—Haim and Lederer (*Monatssch fur Geb. und Gyn.*, Bd. xxv., Hft. 2) record their experiences from twenty-seven cases of ruptured extra-uterine pregnancy, the average age of the women being 30½ years. Four were nulliparæ, nine primiparæ, and the remainder multiparæ. In about half the cases there was previous disease of the genital system. Although gonorrhœa is not always the predisposing cause of extra uterine pregnancy, it is so in very many cases. In two cases the last menstruation had occurred four months previously, in five three months, in seven two months, in seven one to two months, in three one month, and in three two weeks. On the average, the extra-uterine pregnancy came to an end from the second to the third month. The cause of rupture is certainly an erosion of the tubal wall by the growing placental villi. The contractions of the Fallopian tubes are, however, a most important factor in causing the rupture. The authors then describe the different symptoms—anæmia, pulse, temperature, vomiting, tenderness, and dullness of the abdomen, the result of pelvic examination and the discharge of blood per vaginum which they found in sixteen cases. The right tube was the seat of the pregnancy seventeen times, the left nine times. The authors condemn exploratory puncture or curettage in order to make the diagnosis certain. Their treatment is as soon as symptoms of internal hæmorrhage appear find out the source of the bleeding and control it. To do this, they most usually perform laparotomy. As complete a removal of the extravasated blood must be performed as is possible without danger to the patient from prolongation of the operation. They put in a Mikulicz's bag at the conclusion of the operation. Of the twenty-seven patients who were operated on, four died. The convalescence of the others was practically uneventful, and averaged twenty-six days. The after-results were, as a rule, good. In some cases the women had normal intra-uterine pregnancies afterwards. G.

A Contribution to the Question of Eclampsia is made by Gutbrod (*Monatssch. fur Geb. und Gyn.*, Bd. 24, Hft. 5) as follows:—His patient, æt. 40, pregnant for the fourth time, suffered from very severe eclampsia during her first two labours. He saw her at the beginning of her fourth pregnancy, as the last pregnancy had ended in an abortion, but particularly following the advice of Lomer, he gave her iodide of potassium as a prophylactic against eclampsia. During the fifth month of her pregnancy, she threatened to abort, but this was prevented by the usual treatment. The author did not see the patient again till a year and a quarter later, when he was called to her on account of severe eclampsia complicating another labour. She had several convulsions. The urine contained 2 per cent. albumen. Under treatment her labour was soon at an end, and the convulsions ceased. The author then learned that the previous labour before which he had given potassium iodide, had passed off quite easily and without any disturbance. He believes that he sees in this a proof of the efficiency of iodide of potassium as a prophylactic against eclampsia. G.

Mechanical Dilatation of the Cervix Uteri in Obstetrics.—L. H. Leicester (*Jour. Obstet.* and *Gynæcol.*, March, 1907). In this paper the author records his experiences of sixteen cases treated in the Eden Hospital, Calcutta. In seven dilatation was resorted to for eclampsia, in six for rigid cervix, in one each for induction of labour, hydatid mole, and placenta prævia. The instrument used in the first six cases was Bossi's model; in the remainder, Preiss's modification of the same. This latter is far simpler, lighter and easier to clean than Bossi's dilator. Of all the various forms of mechanical dilators he considers that de Seigneux's is undoubtedly the best pattern and least likely to tear the cervix. With the exception of some lacerations of the cervix in four cases, only one of which required suturing, there was no untoward effect which could be attributed to the method of dilatation, and the author thinks these dilators have a distinct place in obstetrical practice, but that the number of cases in which their use is indicated is limited. As to whether it is safe treatment in placenta prævia in any but cases comparatively early in pregnancy, he is exceedingly doubtful, as owing to the friable nature of the lower uterine segment in these cases, there must be a very grave risk of laceration and very serious hæmorrhage. The instrument when in use requires to be very carefully inserted and dilatation to be very slowly proceeded with, a careful watch being kept by the aid of one finger on the cervix. When the cervix is felt to be in the least unduly stretched, dilatation should cease for a short interval, and then resumed more slowly and cautiously than before. This caution is especially necessary if this method is adopted in any case before the cervix is taken up, because, under these circumstances, there is a greater risk of extensive laceration, and for this reason it should only exceptionally be employed in such cases. F.

Prognosis of Pregnancy in Patients with One Kidney.—Ferguson, (*Jour. Obst. and Gyn.*, March, 1907). Nephrectomy is now no uncommon procedure for various diseased conditions of the kidney, and it follows that obstetricians will occasionally be confronted with the question—Should a woman with one kidney be advised to marry and run the risk of becoming a mother? One would, on the whole, prefer that patients who only possess one kidney, even though apparently a healthy one, should, if they marry at all, delay marriage till after the menopause. But one could not, however, give such uncompromising advice, and each case would require to be judged on its own merits. The writer would be strongly inclined to urge in the interests of prudence, that marriage be delayed till at least three years from the operation of nephrectomy, so as to give the remaining healthy kidney ample time for compensatory changes to occur under the influences of the varying vicissitudes of ordinary life—in fact to establish and consolidate a condition of matters which will enable the one kidney safely and easily to do the work usually undertaken by two. If the remaining kidney be diseased, and there is a possibility of child-bearing, marriage should be out of the question. Whenever a pregnancy occurs in a patient with one kidney she should be most carefully watched, her urine being examined and tested regularly during the whole duration of pregnancy, with a view of immediately bringing the pregnancy to an end should she show any evidences of renal inadequacy which fail to respond to treatment. Special care should be taken that the excretion of urea is not diminished, and in this connection it is well to remember the excretion of urea in healthy pregnant women seems to be considerably less than is usually supposed, varying from 20 to 24 grammes in the 24 hours. There is no doubt that urea is always diminished in the toxæmia of pregnancy, and this diminution is of more value, and an earlier indication than either the presence of albumen or casts, both of which latter may be absent even in bad cases. F.

A Case of Premature Birth of Twins.—Martyn, Cambuslang, N.B. (*Brit. Med. Jour.*, March 16th, 1907) records a case of considerable interest. The patient, a primipara, æt. 23 years, expected to be confined about August 10th, 1906, her last menstruation having terminated November 8th, 1905. She first felt fœtal movements early in April. Premature labour, however, took place, and she was confined of twins on June 1st. Both children were females. The exciting cause was hæmorrhage, probably of accidental nature. The first born infant survived but a few hours, the second, much smaller, followed the first rapidly, it cried well at birth. A week after delivery this child weighed only 1 lb. 14 oz., from then till June 30th, it gained nothing in weight, but after that increased progressively till on October 6th it weighed 6 lb. 10 oz. From the onset the child took the breast and throve. The case is remarkable in that without any incubation treatment so premature and small a child should have thriven so well.

A Case of Villous Tumour of the Uterus in a Woman Aged 84 Years—Hysterectomy—Recovery.—Bland-Sutton (*Journal of Obstetrics and Gynæcology of the British Empire*, March, 1907) reports a case of this very rare condition occurring in an old woman. The patient suffered from a blood stained vaginal discharge, the character of which made those in charge of her suspect cancer of the body of the uterus. She was, however, in excellent health. In order to make certain the diagnosis the uterus was curetted, and after microscopic examination was pronounced cancerous. It was thought, however, that the advanced age of the patient contra-indicated operation. Mr. Bland-Sutton saw the case in consultation with a view to operation, and after due consideration, taking into account the patient's excellent health and the small size of the uterus, advised operation. Vaginal hysterectomy was performed by him, and the convalescence was rapid and uneventful. The uterus was hardened in formalin solution, and bisected in its sagittal axis. The uterus was found to be filled with a soft yellowish mass, growing from the endometrium on the posterior wall. Sections cut in such a manner as to involve the walls of the uterus and growth, showed the free portion of the tumour to consist of compound villous processes covered with columnar epithelium, with the exception that the investing epithelium was identical with that covering the normal epithelium, the tumour exactly resembled a villous tumour of the bladder. A further careful examination of the base of the tumour revealed that it consisted of the peculiar cells which compose the reticulum of the normal endomerium. No infiltration of the wall of the uterus was discovered. He considers it from the histological standpoint non-malignant. He has met with one other case similar to the above in a multipara, æt. 54. The present case was also in a multipara.

Chorea During Pregnancy.—Wm. Fletcher Shaw (*Jour. Obstet. Gynæcol.*, April, 1907). In this communication are recorded 11 cases of chorea of pregnancy. The first two cases were treated on traditional lines; the results were bad. It was then decided to try a totally different antitoxæmic treatment, by which the patients were put on a milk diet and elimination was increased. Nine cases were treated in this way with the best results. The idea underlying the experiment was that the toxæmia of pregnancy lowers the resistance of the nervous system, and puts it on a state of heightened irritability, so that it responds to stimuli, chemical, emotional, etc., which would not otherwise produce any result perceptible by ordinary clinical methods of observation. The treatment in these cases consisted of keeping the patient quiet in bed, restricting diet to milk until signs of improvement, when milk foods were allowed; fish and chicken being added when the choreiform movements had practically ceased, and ordinary diet when quite gone for some days. Elimination was increased by acting on the bowels by means of jalap, and on the skin and kidneys by a simple saline mixture. Thyroid Extract was given (30 grains per diem) in five cases with very good clinical results, but as four other cases were treated exactly the same, except that no extract was administered, recovered quite as rapidly, it would appear that the extract does not play a very important part in the treatment. The pregnancy should not be arrested as a rule, as it is generally unnecessary and harmful to the patient as well as to the child. F.

NOTICES TO CORRESPONDENTS, &c.

☛ **CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to his rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

LUTON M.D.—The Finsen Light treatment of Lupus is according to many authorities both tedious and unsatisfactory. Some good results have lately been reported from the injection of iodoform emulsion. There is a great deal to be said for the surgical measures of excision and scraping. The latter, in skilful hands, leaves a little scar, and recurrent nodules (if any) can be promptly dealt with.

K. R. (Bromley).—Certainly, we shall be very pleased to have the article. A case of fracture of the coracoid process of the scapular is worth publishing, especially as you say it resulted in this case from indirect violence.

ROUND IN A MILK-CART.

A **WELL-KNOWN** Birmingham doctor had an amusing experience the other day. He usually covers his round by means of a cab, the driver before starting each morning receiving instructions at which houses he has to call, and the order in which the visits shall be paid. The other day the doctor came out of a patient's house in the neighbourhood of Moseley, but, instead of entering the cab as usual, walked across the road to examine a placard which had attracted his attention. Cabby, thinking his fare secure inside, drove off, but when he arrived at the next stopping place was surprised to find that there was no sign of the doctor. He hurried back, but being unable to find his employer, drove off in the direction of the round it was arranged he should take. The doctor in the meantime, finding himself deserted availed himself of a passing milk float, and in this he continued his calls until cabby once more discovered him.—*Birmingham Daily Mail.*

RUSTICUS X. asks if it is advisable to send a patient suffering from chronic urticaria to Schlangenbad in Germany. Also if there is good hotel accommodation there and what is the nature of the "cure." Perhaps some of our readers will supply the desired information.

MEDICAL STUDENT.—If the ill-treatment continue we would advise you to go to the Dean of your school and lay all the facts before him. This does not necessarily involve official inquiry or action on his part, but in any case he would probably advise you as to the best course to pursue in a difficult situation.

☛ **DR. — BARRETT.**—We have communicated with the author of the Lecture, and will let you know the result.

M. CH. The work is in its sixth edition, and is, we understand, as popular as ever.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, APRIL 10th.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20 Hanover Square, W.).—5.30 p m.: Adjourned Discussion on the Present Position of the Treatment of Tuberculosis by Marine Climates (opened by Dr. A. Street, Westgate-on-Sea). Paper :—Dr. N. H. Forbes : Church Stretton as a Health Resort.

DERMATOLOGICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—5.15 p.m. : Meeting.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.). —8.30 p m. : Discussion on Epilepsy. First Evening : Dr. F. Beach (Historical), Dr. G. Holmes (Pathology), Dr. P. Stewart (Masked Epilepsy), Dr. Mercier (Epileptic Insanity).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. : Mr. J. Clarke: Clinique. (Surgical). 5.15 p.m. :—Lecture :—Dr. N. Tirard : Some Recent Cases of Hæmaturia.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—Cliniques :—2.30 p.m. : Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Out-patient (Dr. Whipham).

THURSDAY, APRIL 11th.

BRITISH GYNÆCOLOGICAL SOCIETY (20 Hanover Square, W.).—8 p.m. : Specimens will be shown by Mr. B. Jessett and Dr. Swanton. Paper :—Prof. Jacobs (Brussels) : The Radical Cure of Prolapsus Uteri.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson : Clinique. (Surgical.) 5.15 p m.: Lecture :—Mr. M. Morris : The Treatment of Some Common Skin Affections.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—2.30 p.m. : Gynæcological Operations (Dr. Giles). Cliniques : Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson). 3 p.m. : Medical In-patient (Dr. Chappel).

FRIDAY, APRIL 12th.

WIMBLEDON AND DISTRICT MEDICAL SOCIETY (Worple Hall, Worple Road, Wimbledon).—9 p.m. : Paper :—Mr. H. Tilley : The Diagnosis and Treatment of Certain Nasal Diseases frequently met with in General Practice.

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8.30 p.m. : Papers :—Mr. G. H. Makins and Mr. P. Sargent : A Note on the Value of Anti-colon Bacillus Serum. Mr. L. McGavin : A Modification of the Method of applying Prepared Filigree of Silver Wire to the Cure of Large Inguinal Herniæ in Males. Mr. W. G. Spencer : Acute Solitary Suppuration in the Psoas and Iliacus Muscles.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. : Mr. S. Stephenson : Clinique. (Eye).

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—9.30 a.m. : Clinique. Surgical Out-patient (Mr. H. Evans). 2.30 p.m. : Surgical Operations (Mr. Edmunds). Cliniques : —Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 p.m. Medical In-patient (Dr. Leslie).

Vacancies.

Torbay Hospital, Torquay.—House Surgeon. Salary £100 per annum, with residence, board, and washing. Applications to H. J. Packe, Secretary.

Bradford Royal Infirmary.—House Surgeon. Salary £100 per annum, with board and residence. Applications to John Barron, Secretary.

The Royal National Orthopædic Hospital, 234 Great Portland Street. Resident House Surgeon. Salary £200 per annum. Applications to the Secretary.

North Staffordshire Infirmary and Eye Hospital, Hartshill, Stoke-on-Trent. House Physician. Salary £100 per annum, with furnished apartments, board, and washing. Applications to the Secretary and House Governor.

Lancashire County Asylum, Winwick, Warrington.—Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, attendance, and washing. Applications to the Medical Superintendent.

West Riding Asylum, Wakefield.—Pathologist and Assistant Medical Officer. Salary £140 per annum, with board, furnished apartments, washing, and attendance. Applications to the Medical Director.

Royal Victoria Infirmary, Newcastle-upon-Tyne.—Director for the Bacteriological Laboratory. Salary £100 per annum. Applications to the Secretary of the Honorary Staff.

Sheffield Union Hospital.—Resident Medical Officer. Salary £100 per annum, with apartments, rations, etc. Applications to Albert Edwd. Booker, Clerk to the Guardians, Union Offices Westbar, Sheffield.

Sheffield Union Hospital —Resident Assistant Medical Officer. Salary £80 per annum, with apartments, rations, etc. Applications to Albert Edwd. Booker, Clerk to the Guardians, Union Offices, Westbar, Sheffield.

Cornwall County Asylum, Bodmin.—Third Assistant Medical Officer. —Salary £140 a year, with furnished rooms, rations, laundry, and attendance. Applications to Medical Superintendent.

Fife District Asylum, Cupar-Fife.—Junior Assistant Medical Officer. Salary £120 per annum, with rooms, board, and attendance. Applications to the Medical Superintendent.

Appointments.

CAPES, ROBERT, M.R.C.S.Eng., L.R.C.P.Lond., Medical Officer to the Camberwell Provident Dispensary.

DRAKE, JOHN ALEXANDER, M.B.Lond., M.R.C.S.Eng., L.R.C.P.Lond., Consulting Physician to the Pembroke and District Infirmary.

ELDER, EDWARD A., B.Sc., M.B., Ch.B.Edin., Senior House Surgeon at the Blackburn and East Lancashire Infirmary.

HAMILL, J. M., M.B., B.Sc.Lond., an Assistant Inspector of Foods in the Medical Department of the Local Government Board.

HOSFORD, ALFRED STROUD, M.R.C.S., L.R.C.P.Lond., Senior Resident Medical Officer to the Royal Hospital for Diseases of the Chest, City Road, E.C.

MELLISH, J. S., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Act for the Tetbury District of the county of Gloucester.

NETTLE, WILLIAM, M.R.C.S., L.S.A., Medical Officer of Health for Liskeard (Cornwall).

PEREIRA, J. A. WENCESLAUS, M.D.Brux., M.R.C.S.Eng., L.R.C.P. Lond., Honorary Surgeon to the Exeter Dispensary.

POSTLETHWAITE, JOSEPH M., M.R.C.S., L.R.C.P.Lond., Junior House Surgeon at the Blackburn and East Lancashire Infirmary.

PULLIN, BINGLEY GIBBES, M.R.C.S., L.S.A., Medical Officer for Sidmouth (Devon).

RICHARDS, S. H., M.B., C.M.Edin., Clinical Assistant to the Chelsea Hospital for Women.

SAYRES, A. W. FORTESCUE, M.D.Brux., L.R.C.P.Lond., M.R.C.S., D.P.H.Lond., Surgeon to the Exeter Dispensary.

SCOTT, SYDNEY R., M.B., M.S.Lond., F.R.C.S.Eng., Aural Surgeon to the Evelina Hospital for Sick Children.

SMITH, S. MAYNARD, M.B., B.S.Lond., F.R.C.S.Eng., Assistant Surgeon to the Victoria Hospital for Children.

Birth.

GREENE.—On April 4th, at Richmond House, Turvey, Beds., the wife of George Watters Greene, M.A., M.D., of a daughter.

Marriages.

MAY—MITCHELL.—On April 6th, at St. Peter's and St. Paul's Church, Chingford, Essex, George Ernest May, M.R.C.S., L.R.C.P., of Ware, Hertfordshire, second son of the late Harry May, M.D., of Parkstone, Dorset, to Racbael Marguerite, second daughter of the late William Augustus Mitchell, of Danes Hill, Bengeo, Hertford.

Deaths.

MITCHELL.—On April 2nd, at Topcliffe, Thirsk, Yorkshire, Thomas Carter Mitchell, M.R.C.S., F.S.A., in his 70th year.

WAKLEY.—On April 5th, at 5 Queens Gate, London, Thomas Henry Wakley, F.R.C.S.Eng., eldest son of the late Thomas Wakley, M.P., aged 86 years.

BRAYE.—On April 3rd, at 20 Ingersoll Road, London, John Gregory ("Jack"), youngest son of the late Hardwick Hubert Braye, M.R.C.S., L.S.A., of South Hackney.

GILLAM.—On April 3rd, at Hillside, Hollington, St. Leonards-on-Sea, Jane, widow of George Jules Gillam, M.R.C.S., L.S.A. Aged 71.

VOL. CXXXIV. WEDNESDAY, APRIL 17, 1907. No. 16

NOTES AND COMMENTS.

Coventry Dispute. THE Coventry fight is continuing, and the eyes of the medical world will be focussed on it for many weeks to come. The conditions at Coventry are typical of those in many other towns, except in that Coventry has its machinery far better organised, and consequently can fight more systematically and strenuously. If the medical men are beaten, then a severe blow will be dealt to concerted action in the profession, for Coventry is a fight for principle and principle only. But we do not believe they will be beaten. The staff of the dispensary, that is those members of it who resigned, are far too well known by their patients for desertion to take place, and the prospect of "blacklegs" is not likely to keep or attract members to the dispensary. As one of the dispensary members wrote to the *Birmingham Gazette*, last week, "I would not like to be a patient under any of these imports, as only those of questionable ability who have been unable to do any good on their own account would apply." As far as we know no "imports" have been brought in, and for the sake of professional honour we trust none will be, but if the people of Coventry are as intelligent as the correspondent of the *Birmingham Gazette*, any such outsider is bound to fail in keeping alive a system against which the profession has decided. The dispensary has had an ample period of grace, and has decided in a way which strikes us as distinctly offensive to pursue its own course. The medical men have countered in the only way possible.

Thomas Beecham. THE death of Mr. Thomas Beecham brings to notice the significant fact that it is possible by what is called "business ability" to amass a fortune out of some every-day drug, while the discoverers of medical principles of enormous life-saving and pain-reducing potentiality have to be content with viewing the advantages that their ability and industry and benevolence have conferred on human beings. If we contrast the career of Beecham, the vendor of pills in the market place who rose to vast wealth through harping on the weakness of his fellow men, with that of Lord Lister, whose magnificent work has made the whole world his debtor, and who never made a penny out of his discovery, the reflection is borne in on one that a State which confers its favours so unequally must be sadly out of joint. Thanks to Beecham's legal troubles the extent of his income has long been public property, and it certainly was of sufficient dimensions to tempt a poor man to leave his every-day routine and indulge in a course of blatant advertisement. The world's work in medicine is done unostentatiously and unselfishly by medical men, and the world's wealth is scooped up by those who do not hesitate to trade on the generosity with which the profession communicates its knowledge to all men for the benefit of mankind. Medical men are said to be "unbusiness-like"; their fellow creatures may thank heaven that they are.

"Ranji" as Sanitarian. THE battle of Waterloo was said by Wellington to have been won on the playing fields at Eton. Is the vast problem of the sanitation of India to be solved on the cricket grounds of Lord's and the Oval? It seems like it. We little dreamt when "Ranji" was delighting the Surrey crowd with his hook strokes and late cuts that when he came into his kingdom his first care would be for its hygienic organisation. No sooner, however, has he assumed his Jamship than he has set about in a determined fashion to remedy the filthy conditions under which his subjects have been accustomed to live and to suffer. He has got together a sanitary corps whose members go about the city of Diwan cleaning and disinfecting plague-stricken houses, and removing the displaced inhabitants to healthy huts till their own hovels are fit for occupation again. Additional medical men have been sent for to help forward the work of plague-prevention, and the Jam is seeking by persuasion and education to get people to conform to irksome restrictions which are designed to minister to their well-being. The plague in India has become such a commonplace that people in England are no longer concerned about it, and the attitude of the central Government is one of resigned despair. If Prince Ranjitsinghi is able to show them the way to rid a state of plague, even his cricket triumphs will pale before the *kudos* such success should bring him.

Seamen's Protest. AN awkward position has been created at Swansea by the action of the Shipping Federation in insisting on medical examination of all seamen before they are allowed to sign on a ship sailing from that port. The employers no doubt feel that with their new and heavier responsibilities under last year's acts they must be more careful to guard themselves against engaging men suffering from infirmity or disease; which, indeed, is very natural. On the other hand the seamen quite as naturally feel that the benefits of those acts will be considerably diminished if they are liable on a doctor's fiat to be prevented from following their employment, especially when the doctor is the servant of their employers. The solution of the difficulty which has these two distinct sides is not easy to see. The free-born Briton naturally likes to have his liberty to the full extent, and also wishes to enjoy the insurance privileges of his dragooned German confrere, and it is by no means easy to see how apart from State insurance, or compulsory payments to friendly societies, the opposing interests are to be reconciled. Other ports besides Swansea are likely to insist on medical examination in the future, and the question may easily become acute, and call for much tactful and statesmanlike handling.

School for Invalids.

The battle is not always to the strong nor the cure always to the quack. There are, *mirabile dictu,* even failures among the irregular practitioners, and of such would seem to be Mrs. Wingett, of Evesham, who lately started a school for invalids, but who has had to close her doors. Why success did not attend her ministrations it is impossible to say, for judging by the notice of the school, which we reproduce below, she was quite as little educated and quite as self-confident, and quite as offensive as most others of her kidney. The notice we refer to adorns the board in front of the school, and runs as follows:

Notice!
A School for Invalids
of all descriptions,
Where Doctors, Physicians, and Hospitals
Have Failed Lessons will be Wrote
or taught by **Mrs. Wingett,**
that will restore health and limbs if attended to
and **Paid** for.

What element of effrontery was wanting, we wonder!

Havens once more.

The ineptitude of machinery of the law in dealing with that class of people who are eccentric and turbulent without being certifiable is illustrated again by a fresh outbreak on the part of Dr. Havens, of Clacton. To the case of this gentleman we have called attention twice already, and we know that the local bench have in vain invoked the aid of the Home Office to enable it to deal suitably with this unfortunate man. His latest escapade took place last week at Clacton, where he was charged with pointing a gun at his next-door neighbour, assaulting him with a spade, and struggling with him on the edge of the cliff. The offences having been proved, the defendant was sent to gaol with a month's hard labour without the option of a fine, and was required to find sureties to keep the peace for twelve months. It is hardly comprehensible that some definite arrangement cannot be made whereby this gentleman might be preserved from being a source of danger to himself and the neighbourhood.

LEADING ARTICLE.

ARMY MEDICAL REFORM.

Now that the question of Army reform is a burning problem in politics, the time is opportune for the setting of the house of the Army Medical Department in order. A nation at peace is apt to forget the stern lessons of war, but of our own countrymen it may be said that successive Governments have done their best to meet the gross defects of system and of administration revealed by the late campaign in South Africa. The total casualties of that war, compiled from official sources, have been given as follows:—

Deaths.	Non-Com. Officers and Men.
Killed in action	5,256
Died of wounds	1,835
Prisoners who died in captivity (cause of death not stated) ...	97
Died of disease	12,911
Accidental deaths	770
Total	20,870

Invalids sent Home.	Non-Com. Officers and Men.
Wounded	8,221
Sick	63,644
Not specified which	449
Total	72,314

A glance at these figures illustrate in a most graphic manner the relative mortality of actual battle and of camp diseases. On approaching the problem we are led to reflect in the first place that it is all, or nearly all, preventable disease with which the Army Medical Corps are called upon to deal. The difference between the disease-incidence of a campaign conducted under ideal sanitary conditions and those of, say, the Peninsular War, would simply be parallel to the death-rate of to-day in the cities of London or of Dublin under modern hygienic conditions as against their terrible mortality in the middle ages. What has been done by civilians among a civil population can be done no less surely by army surgeons working in camps. It is true that special difficulties, more particularly perhaps in the matter of transport, must necessarily be met with in active warfare, but difficulties in such a case should exist only to be overcome. That they are not insuperable has been shown by the experience of the Japanese Army in the late Russo-Japanese war, when the ratio of their diseased to wounded was 1.15 to 1, and of the numbers who died from disease compared with the killed in action, 0.3 to 7.1. This magnificent result was mainly due to the immunity of their troops from epidemic diseases. The Japanese, prodigal and reckless of human life as they were in the face of the enemy, took such precautions in the care of the sick and wounded and in the sanitation of their surroundings that hardly a life was lost from purely preventable medical causes. These apt pupils of the East have not only acquired the art of Western warfare, but have learnt the lesson of its medical science, and have found out in their own supremely clever way how to get at the core of the situation in practice. The task of reorganisation of our Army Medical Department is clearly one of no small difficulty. We may anticipate that the Secretary for War, Mr. Haldane, who has taken it in hand, will not be above availing himself of any hints that may be available from our allies in the East. It is to be hoped that the Government may not be led into the error of reducing the Medical Department. In our opinion the inadequate strength of the Army Medical Department in South Africa was answerable in no small degree for much of the "breakdown." Happily, the period during which active recrimination was a possible factor in the case has lapsed, and the task before us now as a business-like nation is to reorganise our Army Medical Department on such a basis that the nation may use the thews and sinews of her Army to the best advantage in all future campaigns.

CURRENT TOPICS.

Lord Lister and the Royal College of Surgeons (England).

The following letter has been sent to Lord Lister on behalf of the Council of the Royal College of Surgeons of England:—"Dear Lord Lister,—The Council of the Royal College of Surgeons, at their meeting on the 10th inst., deputed us to write and convey to you the sincere good wishes of every member of the Council on the completion of the 80th year of your age. Crowned with honour and regarded with grateful esteem and admiration as you have been for years past, we have heard with great gratification of the further evidences of universal homage which have reached you from all parts of the world on this occasion. But by none are these feelings of esteem and homage more profoundly and genuinely entertained for you than by the members of the Council of this College. We recall with pride and satisfaction that for eight years you occupied a seat on this Council; that your services to the science of surgery have been commemorated by us in making you one of the very small number of recipients of the Honorary Medal of the College; and that your portrait was presented by Fellows and Members of the College in 1897 as an expression of respect and admiration for you as a man, and as a tribute to you as a great benefactor of the human race. This portrait we regard as one of the most valued possessions of the College, and we delight in the fact that it will convey to our successors, for all time, the likeness of him who is, and will always be regarded as, the greatest master of Modern Surgery. We are sure we shall be expressing the thoughts, not only of the present and of ex-members of the Council, but also of every Fellow and Member of this College when we say that you, more than any other who has ever lived, have succeeded in applying scientific and practical surgery to the benefit of mankind, and to the sparing of human life and suffering. The blessings which have followed from your life's work have been innumerable, and the knowledge that they increase and become, as time passes, more and more manifest, must, we feel assured, be a source of extreme happiness and consolation to you in your distinguished and honourable retirement. We are, dear Lord Lister, yours very truly, Henry Morris, president, Edmund Owen and Rickman, J. Godlee, vice-presidents."

The Cost of Sweating.

Medical men probably see more of the evils of sweating than any other class of society. Not only do they visit the poor in their overcrowded tenements, but they see them also in crowds at their surgeries, as well as in the outpatient rooms and wards of hospitals and other medical charities. The story that is laid before them is written in the bold hieroglyphics of want and starvation that sooner or later become stamped on the face and frame of the sweated workpeople. Only last week in London, the richest city in the whole world, two terrible cases of sweating came to light. In one case a coroner elicited from a witness that her family was evicted by the landlord because they could not pay the rent. They made trousers at twopence a pair, and earned in all some five or six shillings a week. In a second case an alien charged with theft was found to have appropriated purses which he was making at twopence a dozen, with the help of his family, he himself supplying the requisite glue and paste out of his own pocket. Now that the Government has safeguarded so amply the future bodily welfare of domestic servants, it would be well if they could find a little time to deal with the case of the sweated work-people. In the long run society has to pay for the workpeople whose health is sacrificed to the greed of the sweating capitalist. Sweating is a bad bargain for the poor and for society, not to mention the harassed medical practitioner, all of whom help to pay the piper.

Public Health in Egypt.

The great administrative powers of Lord Cromer in Egypt have nowhere been more beneficial and conspicuous than in the department of public health. Out of the chaos of numberless centuries the foundation of a system of national sanitation has been evolved. The obstacles in the way of the reformers have been so many and so serious that they might well have appeared insuperable to an ordinary man. The natives, both by tradition and temperament, are averse to the ways of modern hygiene. In the case of ophthalmia, for instance, it is notorious that the brushing away of flies from the affected lids is regarded as a violation of religious teaching. In spite of that attitude, however, a vigorous campaign is being conducted against that scourge, which gives rise to a vast amount of suffering and disability throughout the country. A new ophthalmic hospital will be opened this year at Tinkah to replace the tents in which patients are at present being treated. Some of the other difficulties that have faced the authorities may be gathered from the facts that the Government Anti-rabic Institute has been working since 1906, and that a new asylum has recently been opened at Kahnka. Then, again, excellent results are reported from Major Ronald Ross's campaign against mosquitoes in Port Said, which is said to have greatly diminished the incidence of malarial fever. During last year no fewer than 31,000 in-patients and 128,000 out-patients were treated in Government hospitals. Altogether, the recently issued blue book that contains Lord Cromer's report on the public health administration of Egypt for the year 1906 offers a reassuring proof of the beneficence of the British dynasty in the career of the ancient kingdom of Egypt.

The Reform of Medical Education.

A MEDICAL Congress is being held in Paris, and among the subjects for discussion is the important one of the reform of medical teaching. Educational methods, whether lay or professional, are a moot subject, upon which the last word will probably not be said for generations to come. What is true of education generally applies with equal force to the medical curriculum, which covers a whole galaxy of arts and sciences. The tendency has been more and more to turn out the qualified man full of reflected knowledge upon all branches of his profession. Too often his brilliancies fade into nothingness in the rough and tumble of practice, as he finds himself unable to draw a tooth, to pass a catheter, to perform a tracheotomy, or to diagnose a fracture of the skull. Indeed, most medical men would probably agree with any proposal to extend the practical side of medical teaching. A good solid course of instruction in baby feeding and baby ailments, for instance, would be of inestimable value to the future general practitioner, who is now compelled to spend much of his time in chemical, biological, and other laboratories, doing work which he will in later life have neither the means nor the opportunity of following up. One of the difficulties in the way of effecting any change in medical teaching is the fact that reform would have to begin with the teachers. In the far future it seems likely that medical teachers will receive salaries so ample as to relieve them from the distractions of private practice, their professional skill and experience being gathered solely in the hospitals.

Federal Universities.

THE opinions of the professors and teaching staff of the last remaining federal university in the British Isles on the subject of the federation, proposed by the late Chief Secretary, for their adoption in Ireland, possess a value above that possessed by the opinion of any other similar body of men. In the memorial to which we referred in our last issue, and which was sent by the University of Wales to the Chief Secretary, the following very striking passage occurs :—" We are convinced, by our own experience in the administration of the only remaining federal University in Great Britain, that a federation in which Trinity College should be united with the new College in Dublin, and the existing Colleges at Belfast and Cork, would possess none of the elements which are essential for the successful working of the federal system. In considering the conditions which would exist in the proposed federation, our attention is naturally drawn to their total dissimilarity from those of our own Colleges. They are of the same educational type ; they differ little in age or size ; they possess common ideals ; their partnership was entered upon voluntarily. In the new federation there would be joined together institutions widely diverging in type, with dissimilar conceptions of the aim of a University, and great difference in magnitude and traditions ; and, above all, the union is one which has been declared to be distasteful by all its members, and is strenuously resisted by the one which must, for some time at least, remain the most important. To force a union under such circumstances is, we believe, to court certain failure !" The memorialists also add that " the suggestion that the higher teaching in certain subjects should be given by University, as distinguished from College, Professors, is impracticable in a University in which there is no local union between the Colleges. If attempted, it could only result in the degradation of the Colleges which are situated at a distance from Dublin to the position of institutions of something less than University rank."

The Opsonic Treatment of Pneumonia.

IT is a hideous and dangerous practise which is being adopted by one after another of the leading journals—that of publishing popular medical articles on new subjects. If their object were to instruct the public in ascertained and responsible medical facts and theories, the influence exerted might be very good ; but that is far from their purpose. The idea is to stimulate the palate, jaded with horror and sensations of every sort and kind, to react if possible to medical flummery. There is nothing easier in the world for an unscrupulous writer than to overhaul the medical journals and serve up half-a-dozen fresh " discoveries " every week, each as tentative, ephemeral and disappointing as the rest. The most pretentious form of this pernicious craze is that in which medical terms and facts are used in profusion without regard to the reader's intelligence, merely with the object of making him believe he is sitting at the very fount of science. This last week some flamboyant stuff about the opsonic treatment of pneumonia has been going the rounds, and we venture to think those who have read it are about as wise as to pneumonia and opsonins as when they started. The chief facts ascertained up to date appear to be that the mortality rate of pneumonia in America is 40 per cent., and that opsonic treatment has pulled it down to rather less than 30. The wonder is rather how the pneumonia mortality rate ever got to 40 ; even in this benighted country we can do better than that, even without opsonins. The danger of printing this sort of flap-doodle in lay papers is that any value a new method is found eventually to possess, is discounted in the eyes of the public by the innumerable disappointments which they have already experienced in hearing of its action through these untrustworthy sources.

A Disease or a Vice.

It is not often that the doings of an ecclesiastical assembly are of special interest to us as medical men, but, nevertheless, the debate on temperance matters in the Synod of the Church of Ireland last week really centred round a point on which medical men must eventually come to a decision, although at present they are far from being agreed. Mr. Norman Barnett, F.R.C.S., moved a resolution stating that the present system of dealing with inebriates was based on "the wrong assumption that drunkenness is entirely a vice and not largely a disease," and demanding such a change in the law as would enable magistrates to commit inebriates to inebriate homes for periods of not less than a year. His views met with considerable opposition from some of the clerical members of the Synod, and eventually the resolution was watered down to a mere demand for greater facility in committal to inebriate homes. Without going into the vexed question as to where drunkenness and other drug habits stand in regard to the border line between vice and disease, we are of opinion that any power put into the hands of magistrates must be carefully guarded, and the Synod did well to reject the proposal in the form in which it was put forward.

The Hygiene of the Hop-picker.

The hop and fruit-picking industries of Kent have long been a by-word among decent people. The hoppers who flood this "garden of England" are drawn from the poorest and most uncivilised denizens of East London, and it is not a matter for surprise that they should bring their filthy habits and predatory ways with them. But it is a scandal that the employers of this form of labour should in the past have exercised so little care in catering for the inrush that it has been impossible for these poor creatures to live in anything approaching decency. Even the outbreak of typhoid which decimated Maidstone ten years ago and was clearly traced to the hoppers' excreta did not cause the inhabitants to rise up and insist on proper arrangements being made. The Local Government Board has done well at last to send an inspector, Dr. Reginald Farrar, to report on the matter, and from his report just issued, it seems that with the passing of individual enterprise and the creation of joint-stock fruit-farming companies, some attempt is being made to cope with the housing, sanitary, and other difficult points in the situation. Dr. Farrar found things were not as bad as anticipated, but they are still bad enough. Water when supplied is in many cases either clarified sewage or open to gross contamination; pig-sties and cowsheds—the latter in use for cows—are provided as sleeping-places in some counties, and men and women herded indiscriminately together in others. It will not tend to give people a keener appetite for the strawberries to know under what conditions they are picked, and most of us would probably prefer, apart altogether from the moral principles involved, to pay a little more for our fruit and know that we run less risk of contracting filth-diseases.

PERSONAL.

H.R.H. Princess Louise, Duchess of Argyll, will open the new Out-patient Hall of the London Temperance Hospital on May 14th.

The Duke of Northumberland, K.G., will take the Chair at the annual dinner of the Royal Sanitary Institute at the Langham Hotel on May 15th.

M. Roussilbe's legacy to found a prize for the study of Dermatology has been accepted by the Academy of Medicine of Paris.

Dr. William Cowper, of Frognal Lane, Hampstead, has been the subject of a brutal assault and is very seriously injured.

Dr. and Mrs. James Greenwood, for many years resident in Canonbury, celebrated their golden wedding on April 3rd at their residence at Leyton, Essex. They were the recipients of many valuable presents.

At a meeting of the Committee of the Chester Infirmary last week, Dr. Cyril Dobie was appointed honorary assistant surgeon, and Dr. A. Douglas Hamilton, honorary assistant physician.

Dr. A. McQueen, of Scotland, Ontario, met with a sad death on April 7th. As he was travelling to Winnipeg by train he by some means fell from the car, and the injuries he received proved fatal within a short time.

The Jacksonian Prize of the Royal College of Surgeons for the year 1906, on "The Diagnosis and Treatment of those Diseases and Morbid Growths of the Vertebral Column, Spinal Cord, and Canal, which are amenable to Surgical Operations," has been awarded to Mr. Donald John Armour, F.R.C.S.

Alderman Sir Marcus Samuel, late Lord Mayor of London, has offered to give £2,000 towards the erection of the new operating theatre and the anæsthetic room at the West Kent Hospital, Maidstone, provided that an equal sum is contributed for their endowment. Towards this amount £400 has already been promised.

The honorary degree of LL.D. of the University of Edinburgh, was bestowed on Sir John Tweedy, F.R.C.S., lately president of the Royal College of Surgeons of England, at the Graduation Ceremonial in Edinburgh on Friday last.

The Grand Prix at the International Exhibition at Milan (1906) in the Section of Hygiene has been awarded to the exhibit illustrating researches conducted in the Wellcome Physiological Research Laboratories with a gold medal to each of the Collaborators, Dr. W. Dowson (Director) and Dr. Barger.

Spotted Fever at Leamington.

Newburn Urban District Council last week decided to make cerebro-spinal fever, or "spotted fever," compulsorily notifiable. A case of the disease has occurred at Leamington, and the sufferer, a child, has been removed to the hospital.

A CLINICAL LECTURE
INTRODUCTORY TO
THE STUDY OF DISEASES PECULIAR TO CHILDREN. (a)

By SIR LAMBERT H. ORMSBY, M.D., F.R.C.S.,

Senior Surgeon to the Meath Hospital and Co. Dublin Infirmary, and to the National Children's Hospital.

GENTLEMEN,—You will ask me, in commencing the "Study of Diseases peculiar to Infants and Young Children," how they differ from those affections met with in adult life. Well, in reply to this question many answers could be given to prove that it is advisable to make a special study of such diseases, inasmuch as in the majority of instances the little patient cannot and will not give the practitioner the slightest help in making his diagnosis, which is not so in the study of the same or other diseases in adult life. This gives me the opportunity of informing you what great advantages a large well-equipped children's hospital confers on the community of large. The principal objects of such an institution are briefly:—

(1) A building constructed up to date for the reception and successful treatment of all non-infectious medical and surgical diseases peculiar to infants and young children.

(2) The attainment and diffusion of special knowledge regarding the diseases of children by medical men, students, and others, making a special study of the subject.

(3) The training of nurses for sick children.

With reference to these three objects I could enlarge at great length. However, I will briefly say, the diseases of children must be studied more or less as a speciality, for the correct investigation of such affections requires much special study and constant observation, as children of tender age are seldom, if ever, able to give the physician much help verbally (except by a cry) by way of indication. For this reason all the symptoms and conditions must be carefully observed and scientifically reasoned out, before a correct diagnosis can be arrived at.

The second object, the attainment and diffusion of knowledge regarding the diseases of children, is all important, for such knowledge directly confers a great benefit on the general public because it enables one to know where special advice can be obtained in cases of sudden illness or accident occurring among young children, and also, it may be the means of diminishing the enormous death rate among infants in large cities owing to ignorance in feeding and general management.

The third object, the training of nurses for sick children, is perhaps as important as the two preceding ones. Nurses for infants and young children require a great many qualities if they are to be a success, such as love for children, great patience, great tact, great attention to detail, gentleness, and must know and study "the little ways" and habits of children from babyhood upwards.

In days gone by the entrance to the profession for the student was by a system of apprenticeship, and under this old plan the professional knowledge thus acquired was, to a large extent, traditional, that is to say, it depended largely on the particular medical practitioner to whom the young student was apprenticed. In other words, if an apprentice had the good fortune to be placed under a really good and able instructor in the study of the diseases of children, which forms so large a part of the business of the general practitioner, he would in time become fully acquainted with this very important branch of his profession.

Again, in the various universities and colleges there is very little provision made for the practical instruction in diseases of infants and children. In some there is an attendance required (such as a course of lectures of three or six months duration on the diseases of women and children). But I fear this special subject does not appear to be considered as important as it should, as I am of opinion that the public would naturally expect to find that some provision had been made in the different medical schools and colleges for the teaching of this special branch of medicine and surgery to the students. Specialism in nearly every branch of medicine and surgery to-day is a most important feature, and what further development it will reach in the near future it is impossible to say. But no matter what specialism a practitioner may hereafter devote his whole attention to, it would be better for him at first to engage for a few years in general practice so as to obtain a thorough and comprehensive grasp of disease in all its forms before taking up the study of a given special branch suitable to his abilities and tastes.

In the clinical investigation of disease in infants and young children a practitioner is confronted with enormous difficulties. But before proceeding further we must understand that early life is divided into two periods, viz.: Infancy and childhood. Infancy commences at birth and terminates on the complete eruption of the milk teeth, an event which, as a rule, occurs about the end of the second year. Childhood then begins and extends from this age to the period of puberty between the thirteenth and fifteenth year. In conducting the investigation of disease in an infant or a child it is useful to proceed in systematic stages and methods, viz.:—(1st) By questioning the parents or attendants; (2nd) by inspecting the infant or child; (3rd) by physical examination of the little patient.

I.—QUESTIONING THE PARENTS OR ATTENDANTS.

In infant and childhood life this mode of obtaining accurate knowledge concerning the condition of the patient is one of the means we have to adopt for eliciting information. We therefore depend, to a large extent, on the testimony and report of those who are constantly about the patient. Parents, nurses, and servants at times can give the physician excellent clues and help in this way, and although they may not be remarkable for their intelligence in other matters they can be valuable observers when their powers are guided by affection and regard. Besides being always about the child and knowing every turn and peculiarity as well as the habits and disposition they will often detect any deviation from the child's ordinary health much quicker than the physician will during his short and casual visit. As this mode of obtaining information requires some definite order we might divide our means of interrogation into three:

1. The family history, as a rule, gives help and may be of use as regards whether the infant or child is the subject of transmissable or hereditary disease such as tuberculosis, syphilis, etc., and whether other children of the same family have been similarly affected, or whether any of them have died, and at what age, and from what cause, or if similarly affected, if they recovered, what period it took to recover, and the treatment adopted.

2. We must then investigate accurately concerning

(a) **Being the subject of a Lecture delivered to the students attending the National Children's Hospital during the Session 1906-7.**

whether the child is fed at the breast, or artificially by means of the bottle, and if by the latter the composition of the food employed; then its whole environment must be considered as regards its sleep, food, exercise, and general hygienic surroundings.

3. The next important point is to question the attendants, how and when the attack came on? Get them to fix the exact date when the child was quite well, and then state from that time the changes which came over the child, as regards its sleep, food, irritability of temper, cough, convulsions, diarrhœa or vomiting, heat of skin, pale or flushed face, as the case may be.

II.—INSPECTION OF THE INFANT OR CHILD.

When a baby or small child is suddenly brought into the presence of the doctor for the first time for examination it requires the greatest care and tact on his part not to frighten the child or make it cry, for if it gets frightened, disturbed, or cries, it will only make it harder for the physician to arrive at a correct diagnosis as regards the little patient's real condition. If the baby is asleep tell the nurse not to awake it suddenly, much can be observed by the experienced child's doctor while the little patient sleeps—the heat and colour of the skin, the restful or unrestful position the patient reposes in, the regularity of the respiration, whether slow or quick, whether full or shallow, whether laboured, or sighing. Then the frequency and character of the pulse can be felt much easier when the patient is asleep. Suppose the child is awake when you see it for the first time do something at once to attract its attention by showing it a toy or some tinkling instrument—your watch is very useful to show a child and let it feel it. A physician accustomed to examine many little children will need to be most resourceful and will find by judiciously getting the child or baby's confidence at once, he will have very little difficulty in his future examination, and it will not be disturbed by a violent crying fit. It is better at first to talk to the mother or nurse, and apparently take no notice of the child and so allow it to take a good look at you and all the new surroundings of your consulting room, and if the child can run about let it do so without restraint, and the little patient will soon feel at home, and you can then conduct your examination with much more ease, quickness, and satisfaction. I never consider an examination complete without removing all the child's clothes; as much can be ascertained by complete inspection of the child's naked body. This sometimes makes the child cry, but still it is far better to have a full examination than a partial one. However, wait for a moment or two till the child gets accustomed to you before asking this to be done.

When a child is really sick and "out of sorts" the mother or nurse will have noticed it, and that is the reason why you have been sent for to see the child, or the child has been brought to you, therefore, you need not waste time by endeavouring to ascertain whether it is sick or not, as by its history, appearance, etc., the fact will be obvious. Your business, as a physician, is to ascertain to what extent the child is ill, what is the complaint it suffers from, and what is the best treatment to be adopted which will speedily effect a cure.

1. *The Face.*—It is surprising how much can be learned by an experienced eye by simply looking intently at a baby's face. Take a healthy infant and carefully observe it in a peaceful slumber. What an expression of perfect repose and healthy contentment is here apparent. When it is ill and "out of sorts" what a remarkable change is observable. The face is pale and contracted. The eye is dull and glassy and has lost all its brightness, with twitching of the eye-lids and lips, the faint and continuous whining cry, showing the child is in pain, and the constant wriggling or writhing in its little cot or in the nurse's arms, shows that it is ill at ease. Dilatation of the alæ-nasi, with or without heavy breathing, indicates impeded respiration, the result of broncho-pneumonia, or a pleuritic attack.

Then when the healthy child is awake look at its bright eyes together with its cheerful happy expression, observant of everything and smiling at all around it. This expression of countenance is greatly altered by the onset of any illness just as a storm changes the whole aspect of things after a period of peace and sunshine. The change being in proportion to the severity of the attack. An expression of pain and anxiety is quickly delineated in the face, the features become pinched, and the eyes and mouth become drawn and contracted. Pain undeniably sets its mark upon the facial muscles of expression, and by noting the features affected it is often possible to fix the seat of disease or derangement. Thus, contracting of the eyebrows denotes pain in the head, sharpness of the nostrils pain in the chest, and a drawing of the upper lip pain in the abdomen. It has been said, and said correctly, that the upper third of the face is modified in expression, in affections of the brain. The middle third in diseases of the chest, and the lower third in lesions and diseases of the abdominal viscera.

2. *Posture.*—When a healthy child is lying in its little cot or bed it slumbers on in the most peaceful manner, it rests in an easy and comfortable position, the breathing is quiet, regular, and silent, and the only movement that can be observed is the gentle rise and fall of the abdomen and chest in respiration. When a child is ill the whole scene changes. The infant tosses and turns about, and is only content when rocked in the cradle or taken up and fondled or walked about with, in the nurse's arms. The older child whinges and cries and begs to be taken out of bed and raised, many positions are assumed, according to the presence of various diseases. In abdominal and peritonitic pain the child lies on its back with the legs well drawn up, so as to relax the abdominal muscles. Restless movements of the head or burying of the head into the pillow, or where the head is bent back as the child lies on its back indicates cerebral and meningitic trouble.

Persistent lying on the face and burying the face into the pillow so as to hide the eyes from the light is an evidence of photophobia. When the thumbs are tightly contracted on the palms of the hands it is just possible a convulsion may be pending. In the last stages of febrile attacks the patient lies quiet and stretched out and is unable to move hand or foot from sheer debility, and in stupor and coma the body is also still and immobile from the same cause.

3. *State of the Skin.*—The condition of the skin in infants and young children is very important, and much can be learned by a careful observation of its external tegumentary covering. In the new-born infant the colour of the skin varies from a deep to a light shade of red. After a week or ten days the skin assumes its typical healthy appearance. Lividity of the eyelids and lips is a sign of imperfect aeration of the blood, and points to pulmonary or cardiac disease. Marked blueness of the whole face is a sign of "morbus cæruleus," and indicates a congenital malformation of the heart or a non-closure of the "foramen ovale." A yellow discoloration of the whole skin with a yellow hue in the conjunctive indicates jaundice, whereas an earthy tinge of the face is met with in chronic intestinal diseases, a waxy pallor in renal diseases and paleness in any diseases attended with exhaustion. The eruptions met with are numerous and varied. Eczema perhaps of all the skin eruptions is the most common. The skin in a child is very variable as regards the ranges of temperature, and is not at all as regular as it is in adult life.

4. *Mode of Drinking or Taking Nourishment.*—This is important for, by watching an infant sucking at the breast, or the teat of the bottle, much knowledge can be obtained both of the strength of the child and the condition of its mouth, throat, and respiratory organs. If the mouth is any way sore the nipple is held only for a moment or two and then discarded with a faint cry of pain. When the throat is affected swallowing is performed in a gulping manner, and an expression of pain passes over the face and no more efforts are made than is just required to satisfy the pangs of hunger. Under similar circumstances older children drink little and refuse solid food altogether.

An infant suffering from any bronchitic or pneumonic affection sucks spasmodically, and pauses now and then to get its breath. In older children the act of drinking is carried out in the same way with numerous interruptions. If the finger is placed in an infant's mouth in health it sucks vigorously, if weak or debilitated it is hardly able to grasp it, and if it does it sucks faintly and imperfectly.

5. *Character of the Cry.*—Crying, it has been said, is the chief, if not the only, means that the young infant possesses of making known its pain, displeasure or discomfort. Even long after the powers of speech are developed the cry is the common channel of complaint to those around. Incessant unappeasable crying is often due to hunger or pain in the head or abdomen. Conditions of general distress, great debility and malaise predispose to fits of fretful crying, the paroxysms being excited by any disturbing influence such as the presence of a stranger or change of nurse. When the cry has a nasal tone it indicates a swelling of the mucous membrane of nares, pharynx, or the presence of enlarged tonsils or adenoids. A loud brassy cry frequently announces the onset of an attack of spasmodic croup. In membraneous croup and in extreme exhaustion the cry is faint and inaudible.

6. *The Character and Condition of Breath.*—The breath of a perfectly healthy infant or child should be odourless or what nurses call "sweet." It may just after taking nourishment smell of the milk or other food taken, but this lasts only a very short time. Any persistent sour smell from the breath is an indication that the child is not in health. Fœtor of the breath is observed in such affections as aphthous and ulcerative stomatitis, also in a more aggravated form in ozoena and necrosis of the nasal and maxillary bones. Decaying teeth give much the same odour, though it is less strong and penetrating. Sour breath is present in infants especially when there is gastric fermentation and gastro-intestinal catarrh. What is known as a feverish breath has a heavy sweetish smell. It is met with in infantile disorders accompanied with high temperature such as measles, scarlatina.

7. *Character and Frequency of the Pulse.*—To obtain anything like an accurate idea of the pulse it must be felt when the patient is perfectly quiet. The best time to feel it is when the child is asleep, but unless it is felt with the greatest care the child is likely to awake, and then it will doubtless indulge in a fit of crying and will as a matter of course raise the pulse rate so that it is hard to ascertain its average character and frequency accurately. With very young infants it is very hard to feel the radial pulse at the wrist. It may be felt over the anterior temporal artery on the forehead, or it may be ascertained by means of the stethoscope over the heart itself. The pulse in an infant from birth to the second month averages from 130 to 160, and from the second month to the sixth month 120 to 130, and from the sixth to the twelfth month 110 to 120, and slows down gradually to the age of puberty. In scarlatina a pulse of 160 need not alarm, in fact its frequency is quite common.

8. *The Temperature.*—This fluctuates considerably in infants and young children. It may be roughly ascertained by feeling the face, forehead, or body with the hand. But to be accurate the thermometer must be used, and it may be placed in the mouth, rectum, axilla or groin. If placed in the mouth the thermometer must be held, and the mercury carefully watched as it rises. If the child cries it will have to be removed and placed in the axilla, in either groin at side of scrotum or labia, or if one requires the temperature to be really accurate the rectum had better be selected. In an infant it must be remembered that the temperature in the rectum is one degree higher than the axilla and in the groin about one degree lower than the axilla. Rapid and transient rises attend slight catarrhs and gastro-intestinal attacks. The degree of elevation marks the type of pyrexia present. It is moderate at 102. Severe at 104 or 105, and very severe when it reaches 107.

9. *The Respiration.*—In infants and children the breathing is mainly abdominal, or costo-inferior, and it is not till the age of puberty that the breathing can be said to be (in the female) costo-superior. Therefore, when it is necessary to count the respirations, the hand should be lightly placed on the child's abdomen over the epigastrium, and the respiration should be counted by the second-hand of the watch. As regards the rate: Soon after birth the number of respirations is 44 per minute, and from two months to two years 35, and from two to twelve years about 23. During sleep the frequency is reduced nearly 20 per cent. Rapid breathing is generally met with in the elevation of the body temperature, and found in all cases of febrile states, also in thoracic and abdominal pain. Diminished frequency is found in certain brain diseases, such as chronic hydrocephalus and in the last stages of tubercular meningitis. Perfectly healthy breathing is carried on through the nasal passages so softly and without noise that it is difficult to perceive it. When there is any stoppage in the throat or partial obstruction of the nasal passages by adenoids, the breathing is carried on through the mouth, and gives the child a marked change in aspect and appearance. "Mouth breathing" is very common, and, in my opinion, frequently is the main cause in the production of adenoids.

10. *Movement of the Bowels.* The daily number of evacuations varies considerably in children, depending on age, food, and surroundings. During the first six weeks of life there are generally three or four stools in the 24 hours. After this time, up to the end of the second year, two movements in the day is the average. After this the frequency of defæcation is the same as in adults, once in the 24 hours. The character, such as odour, colour, consistence, of stools is very important, and present a very valuable means of diagnosis. From this it will serve to show how much can be learned from the examination of the stools and the importance of making a personal inspection of them.

11. *The Voiding of Urine.*—It is impossible to say how often a healthy infant will void its urine in the 24 hours. It is subject to great variation—it depends on the temperature, the time of year, the amount of exercise, and general surroundings. It may be every hour during the day and three or four times during the night. The urine of a healthy infant should not stain the diaper, the fluid being clear and colourless. It has, as a rule, a low specific gravity, 1003 to 1006, and slightly acid reaction. Painful micturition is found in inflammatian of the urethra, a tight prepuce, a highly acid state of the urine, or the presence of stone in the bladder. The normal daily amount voided in the 24 hours is subject to variations. Between two and five years average quantity voided, 15 to 25 ounces; five and nine years, 25 to 35 ounces; nine and fifteen years, 35 to 40 ounces.

12. *Vomiting.*—This is a very common occurrence in infants and young children, and must be distinguished from regurgitation of the contents of the stomach which seem to come up without effort, and occurs when the infant sucks in the milk too fast and more than it can conveniently digest, and the stomach relieves itself by regurgitation of the undue supply, this may be considered a sign of health rather than of disease. Retching and purging is frequently met with in young infants who are improperly fed, and is a common symptom of gastro-intestinal catarrh, enteritis, or colitis. The vomiting of mouthfuls of curdled milk, or partially digested food is an indication of fermentation and the formation of acid in the stomach, and that digestion and assimilation is not taking place.

III.—PHYSICAL EXAMINATION.

In the physical examination of the infant and young child, it is better to adopt some regular methodical order of examination, and, as I said before, the physician must use all the tact, judgment, gentleness, and resourcefulness in his power in order to carry out a successful physical examination of his little patients. He must before he does anything to the child endeavour to gain its confidence. Various children have to be approached in different ways, and the person who has the greatest experience will at a glance know best how the little patient before him has to be humoured into acquiescence and good behaviour during the examination. Before stripping the body, observe the condition of the pulse, respiration, and temperature; then, when the clothes are removed, inspect the muscular development of the body and the limbs, winding up with the mouth, tongue and fauces. Much information will thus be derived by following this order of examination.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Professor Wm. Carter, M.D., F.R.C.P., LL.D. Lond., Senior Physician to the Royal Southern Hospital, Liverpool. Professor of Therapeutics in the University of Liverpool. Subject: "Some Cases of Nervous Disease."*

ORIGINAL PAPERS.

THE NON-OPERATIVE TREATMENT OF MALIGNANT DISEASE. (*a*)

By W. A. POTTS, B.A. Cantab., M.D. Ed., M.D. Birm.

Lecturer on Pharmacology at the University of Birmingham.

The methods of treatment I am going to discuss are not intended as substitutes for surgery. The opinion of our profession is unanimous in favour of an operation whenever possible, once cancer is diagnosed. There must always however, be a residuum of cases in which surgical methods cannot be adopted. In spite, too, of many and increasing triumphs, cases do recur; the surgeon then may still be the patient's best friend, as for instance when he does a palliative colotomy. Such treatment, however, is beyond my province, nor do I propose discussing proceedings which profess no more than relief of symptoms. This paper is limited to some three or four new courses of treatment, credited with a chance of cure, if undertaken at an early stage; whether they ever effect that desirable result or no, they may be useful for other reasons to those who have to see the case through.

The diagnosis of cancer presents almost insuperable difficulties, especially as some surgeons now question an opinion backed by microscopic examination. Extremists may insist that none of the cases cured by the means we are going to consider were genuine cases of sarcoma or carcinoma. I shall not attempt to fight that contention, but at once take up a safer position, and say that it is important to know remedies that have been successful in conditions which so closely resemble cancer as to mislead the most experienced. I use the word cancer in its widest medical sense, and attempt no definition.

The electrical methods of treating cancer may be temporarily put on one side, as another member of this society has promised a paper on that important subject.

In a few words we may dismiss Doyen's serum, an anti-toxin obtained from horses; Doyen starts with the assumption that cancer is due to the micrococcus neoformans, and prepares his remedy accordingly; it has, however, been discredited by other surgeons in France, while in this country, Paine and Morgan, after careful trial in a series of cases at the Cancer Hospital and elsewhere, have come to the conclusion that the serum is always useless, and sometimes dangerous; occasionally it set up severe pain.

I pass at once therefore to review the treatment by trypsin, so indefatigably advocated by Shaw-Mackenzie. This is placed first, because it was the means of curing a mouse inoculated with cancer by Beard, a success not achieved to my knowledge by any other method. The trypsin-dosed mouse is alive to-day, while another, used as a control, and therefore not treated, died after exhibiting the usual symptoms of advanced cancer. Treatment consists in the injection of 15 minims of a 2 per cent. solution, the dose being repeated every other day, and increased each time by 5 minims. The needle may be passed into the abdominal wall, or the gluteal region, or into the neighbourhood of the tumour; the best results are obtained when such local application is practicable. The medicine may also be administered by the mouth, and lately there have been used in addition preparations of intestinal glands containing "secretin," or "erepsin" and "enterokinase." Strict asepsis is necessary; there is no contra-indication to the method, which, even when unsuccessful, gives rise to no unpleasant symptoms. The action is a digestive one, the tumour gradually disappearing. Trypsin dissolves cholesterin, and Shaw-Mackenzie has demonstrated that this property is shared by certain other drugs, such as chian turpentine and sodium oleate solutions, which have been used for cancer. Chian turpentine, by mouth administration, was thoroughly exploited in Birmingham some twenty-five years ago, when it fell into disrepute. As Shaw-Mackenzie claims to have afforded relief by subcutaneous injection, I may remind you that this treatment consists in injecting 5 minims of a 20 per cent. solution of chian turpentine in olive oil, and increasing by 5 minims on alternate days up to 60 minims. The preparation should be deeply injected into the buttock, after sterilising the site of injection, local anæsthesia may be induced by a piece of block ice, followed up if necessary by eucaine. The action probably consists in cutting off the nutrient supply to the growth.

Oleate of soda injections were recommended by Webb of Melbourne, in 1901; one drachm doses are used, pain being obviated by eucaine; the effect is enhanced by internal administration of ox-gall, whose palliative effects in cancer have been known from the earliest times. The beneficial action of these cholesterin-dissolving substances depends for explanation on Webb's theory that "cell proliferation is due to the deposition of cholesterin in the tissues, either locally from injury or some nutritional disturbance in the liver, associated with deficiency of the bile soaps, which normally hold cholesterin in solution." Of these drugs Shaw-Mackenzie claims trypsin to be the most efficacious and explains that it has the effect, which pepsin has not, of breaking up glycogen; glycogen is always present in the cancer mass. In advanced cases trypsin is of value in checking fœtor and hæmorrhage.

The next drug, cinnamate of sodium, was recommended by Drage last year; he suggested either cinnamate or orthocinnamate of sodium, 30 minims of the former in a 10 per cent. solution, or 25 minims of the latter in a 22 per cent. solution; one of these should be injected once or twice a week for three months. In his more recent paper he seemed to pin his faith to the coumarate. Like Shaw Mackenzie, he holds out no prospect of a cure unless treatment is commenced early, but apart from such a desirable issue, commends the method for controlling symptoms, particularly hæmorrhage, pain, and discharge. Drage states that the same procedure acts well in tubercular cases, and pleads for its use in the pre-cancerous stage; many chronic and obscure abdominal conditions clear up if dealt with in this way. I have used it in two cases, and can support some of the claims advanced, but no favourable influence was exercised on the fœtor of the discharge. My experience points to the coumarate being the more valuable drug, and to the advantage of pushing it; I worked up to double the quantity of the solution recommended. At the same time three months seems to be insufficient. In one of my cases this treatment was discontinued after three months, and the progress of the disease then appeared to be much more rapid; on resuming after an interval of six weeks, an inhibitory action was again in evidence. No bad symptoms resulted. The action is an extensive leucocytosis; Drage says that "what causes a large increase in the most organised cells will also cause such

---

(*a*) Paper read before the Midland Medical Society.

an alteration in the environments of cells which have reverted to the genetic type that an arrest in their inversion is possible and probable.

I wish next to give you a few details of a drug in which I am specially interested, namely, an infusion of violet leaves. When first used the infusion was made by the patient or his friends by the simple process of pouring a pint of boiling water over a handful of leaves, and then straining 24 hours later; half the liquor was drunk during the succeeding 24 hours, and the other half used for local application. Mr. Whippell Gadd made some investigations from a chemical standpoint, and came to the conclusion that the active principle was a glucoside, viola-quercitrin, of which there is 5 per cent. in a properly prepared infusion. He has placed on the market a purified solution of the glucoside in which alcohol is used as a preservative. The treatment appeared to be one with possibilities; accordingly I began using it in two cases where the resources of surgery had been exhausted. At the same time I undertook a series of pharmacological experiments in order to place the treatment on a scientific basis; this was, I believe, the first pharmacological study of the drug. I will not weary you with details, as they have been placed in full before the Therapeutical Society, and published in the *Medical Magazine* for November. On the board is a diagrammatic scheme of some of the tracings I have taken. The net result of the experiments has been to show that the drug is non-toxic in ordinary quantities, but far from inert. It depresses all muscular tissue, particularly the heart, and in consequence causes a marked fall of blood pressure. There is no effect on the central nervous system, but the nerve endings are so influenced, both after local and internal administration, as to constitute this preparation an analgesic of great value. One of the most conspicuous clinical actions consists in diminishing the fœtor of discharge; this has been noticed by many observers. It is not due to liquor violae glucosidae being antiseptic, for it is not; it seems almost certain, however, that after absorption, the active principle is split up into something else, with disinfectant properties. The obvious action is to control pain, hæmorrhage, and discharge; it is therefore beneficial in cancer. As a matter of fact it is a drug with a wide sphere of usefulness; possibly, though first introduced for cancer, it may ultimately be used even more for other conditions. The only drawbacks are the nauseous taste, and tendency to cause dyspepsia; they are, however, largely discounted by the fact I have established that the best results are obtained by hypodermic injection. It will be interesting to see further results of this method of administration, which had not been attempted previously. I recommend injecting half to one drachm of liquor violae glucosidae twice daily, near the tumour if possible, but as with the cinnamate I think the drug should be pushed. I took one and a half ounces without ill effect. The depressing action prevents its use when the heart is feeble; there is no other risk; the drug is so active and so rapidly eliminated that any bad symptoms develop immediately after administration, and are therefore under control; cardiac stimulants constitute the antidote. Among numerous cases reported, nothing really alarming has been noticed. Liquor violae glucosidae is a valuable palliative in cancer; to be anything more it must be given at a very early stage. Gordon has recorded several successful cases; from a study of these it appears that the cure is effected in a few weeks, if effected at all; after a time it loses its power. The clinical results are foreshadowed by the pharmacological experiments, which indicate a rapidly produced action with the subsequent development of tolerance. It ought, therefore, to be given the first trial, as it is soon known whether it is going to help or not. If not, little time has been wasted, before other treatment is instituted. There is no objection to running more than one of these methods at the same time, although their action is not the same. In both my last two cases, violet leaves and cinnamate of sodium were used simultaneously. The action of violet leaves is not digestive; precisely how it acts we do not know; several details, such as the mode of elimination, are still moot points. The lowering of blood pressure and antiseptic action after absorption must both contribute towards a favourable result, which is possibly due to diminished nutrient supply to the growth, combined with a shelling-out process due to the shortening of any contractile fibres present. As a rough guide to a choice between various methods I may say that while trypsin is indicated at a very early stage, I do not recommend it so much later, when only a palliative is aimed at; then, if hæmorrhage is the chief trouble the cinnamate should be used; for offensive discharge and pain violet leaves is the drug *par excellence*; as a hot fomentation it often acts like a charm.

Diet must next occupy our attention. Food has considerable influence on the general condition, and the previous health must sometimes determine the incidence of cancer. With this assumption I suggest a change in diet, directly a diagnosis is made, on the ground that the course adopted antecedently cannot have been a prophylactic one. I recommend a decided variation from the previous plan, rather than the prescribing of any particular scheme. There are many systems worth trying, and I would just mention two—(1) the two-meal system; (2) a purin free diet. In cancer one or both would appear to be the right course. The stuffing and stimulating systems have been given such an exhaustive trial, and have been so conspicuously unsuccessful, that experiment might well be made of quite different methods. Such thoughtful and observant men as Sir James Paget and Sir Mitchell Banks have indeed connected cancer with over-feeding. At this point we may call to mind that in Ireland during the potato famine the death-rate from cancer fell considerably. Possibly some medical men believe either plan of diet suggested would accelerate a fatal issue. From experiments repeatedly carried out for months at a time during the last eight years, I can assure them that their fears are groundless. As a matter of fact, we should be doing our patients a real kindness; scarcely anything increases sensitiveness to pain more than do stimulants and generous feeding; few courses diminish it more than an abstemious and spare diet. I do not say one of these schemes will suit everybody. Something, however, on these lines will be of value, especially if the precautions I have elsewhere insisted on in connection with a change of diet are enforced. In my paper on the action and the results of violet leaf preparations will be found notes of a case treated by violet leaves, cinnamate of sodium and a purin free diet. These were instituted after an abdominal section had revealed that surgical treatment was impossible. The patient ultimately recovered. This case is referred to now, not so much as an instance of a cure of cancer—for the disease was probably not cancer after all—as an example of the beneficial action of these courses of treatment even for a patient almost *in extremis*. If one of them were adopted at the time of operation a great step would be taken towards reducing the risk of recurrence. An operation is sometimes undertaken when, according to Mr. Pearce Gould, the mortality for the particular patient is 100 per cent. Regarded as an adjunct to surgery, violet leaves or other drug, and diet, might reduce the risk to nothing per cent.

How do matters really stand? We have no cure for advanced cancer, that is certain. I am, of course, ignoring surgery for the moment. Even at the commencement a cure is but seldom effected with all our resources. Would it not be well, then, to aim at prevention?

It may at once be asked, how can you prevent cancer when you do not know its cause? Sometimes we know more than we will admit, and long ago I joined sides with Professor Clouston when he said that if, instead of eternally clamouring for fresh facts and more statistics, we would sit down and make all possible deductions from the information already available, we should find we really know enough to be able to teach the public how to almost entirely prevent disease. Is it quite true, as is sometimes said by those who overlook the obvious in a vain search for what is occult and perplexing, that we know nothing about cancer? On the contrary, it seems to be generally admitted that the cause is irritation. It is scarcely necessary to remind you of the evidence in favour of this view, derived from the fact that cancer occurs chiefly in situations exposed to irritation; or do more than call to your minds the frequency with which it is grafted on an old ulcer of the stomach, or a lacerated cervix. Everything which irritates the tissues, especially if the irritation is long continued, must tend towards cancer, which can scarcely have a single origin. Some day perhaps the precise organism associated with its incidence will be determined; that discovery would not really be so valuable as the one already made, that irritation is the root of the mischief; even when the pathologist can tell us exactly how and why cancer develops, we shall probably have to hark back, just as in the case of tubercular disease, and prevent it by a prophylactic mode of life which had been suggested years before. Victims of cancer have usually had warning symptoms for many years, but the invidious distinction between functional and organic disease, combined with the fatal policy too often advocated of waiting to meet trouble till trouble comes, frequently militate against a correct interpretation of the writing on the wall. The laboratory will seldom boast a greater triumph than the finding that healthy tissues are the best germicides.

To prevent cancer all sources of irritation must be removed; this will never be completely achieved, and so we can never hope to eliminate cancer. We ought, however, to succeed in greatly reducing its frequency. To do this we must set our standard of health much higher than we usually do, and avoid all known sources of irritation to our systems. I agree with Keetley that much may be done in this direction, and commend to you his suggestions that special care should be taken of the mouth and teeth, and a sufficient and regular toilet and protection advocated for the nipples and genital organs, both of which, among the lower classes at least, are often shamefully neglected; frequently they are polluted by stale secretion, especially during lactation. A caution must be added as regards constipation; this should be taken far more seriously; those who gloss it over as not inconsistent with health do not know the meanings of words. It is of course, a clear indication that the diet is unsuitable and should be treated accordingly. I cannot agree with Keetley's first suggestion that all food should be sterilised, because we know that animals fed entirely on sterilised food soon die. Had he confined himself to recommending that the loaf should be prevented from rolling in the gutter before reaching the consumer, and the joint not exposed to the dirt and dust wafted upon it by every wind that blows, I should have been in complete agreement. Personally, I cannot accept the dictum of the Cancer Commission that diet has nothing to do with cancer. No one is in a position to say so yet; the subject of dietetics, well worthy of a lifelong study, is only in its infancy. No proofs can be given connecting cancer with diet. We know, however, that the non-meat-eating countries, have a much lower death-rate from cancer than we have; in lower Egypt it is 1 in 1,028, as compared with our 1 in 29. On the other hand, the excessive meat-eating countries, such as Australia and New Zealand, are near our mark. Again during the last 50 years, while cancer has been increasing so much, the one marked change in our diet has been the much greater consumption of meat, as shown by the statistics of Chalmers Watson and others. These facts prove nothing, but must make the judicious ponder. We now know that meat can never be got free from ptomaines, and the more we know of ptomaines the less we like them. We also know that the viscosity of the blood can be increased by a meat diet, as shown by Burton-Opitz, of New York, thereby increasing friction, and so possibly causing irritation. In this connection Chalmers Watson's experiments as to the effects of an excess of meat on rats, and similar work in France on birds some years previously, must occur to thoughtful men.

There are many other sources of irritation in food, but time is too limited to refer to more than one, namely, salt. Salt has often been put forward as a cause of cancer, and health enthusiasts long ago eliminated it from their diet. The scientific as a rule scoffed, but the definite proofs discovered during the last year of its irritating action and the benefit effected by physicians in Germany and elsewhere, who have withheld it in cases that were doing badly, indicate that perhaps, after all, it was not such a wild idea to place salt among the many sources of irritation which tend towards the development of cancer. It is significant that in Austro-Hungary, the highest mortality from cancer is found in the province of Salzburg, where the production of salt is the chief industry. The two-meal system already referred to was promulgated over two hundered years ago by Luigi Cornaro, whose estimate of the proper amount of food was much the same as Chittenden's; this has ever since been practised from time to time by a certain number. The non-meat diet for cancer was advocated nearly a hundred years ago. Should we adopt either of these suggestions now, we might well hope to escape the reflection so dreaded by some, that we are like the Athenians, and patronise only what is new. In conclusion, I would say that some may think I attach too much importance to diet; if the imputation could be made with truth, I should still welcome it; the subject has been in the past so neglected by medical schools that till someone goes to to the opposite extreme we shall never attain that happy mean which has always been the ideal of the profession.

OPERATIVE TREATMENT OF TRAUMATIC PSYCHOSIS.

By BERNARD HOLLANDER, M.D., M.R.C.S., L.R.C.P. LOND.

CAN mental derangement at least in its early stages, be remedied by surgical treatment? The unanimous answer will still be "no," although, as I have shown in my work on "The Mental Functions of the Brain," there are nearly a thousand cases on record in which the disease has been limited in extent and localisation of the symptoms was possible. In my own experience the hypothesis of localisation has helped me to trace in a large number of cases the cause of the morbid change to injury, sometimes apparently so slight as to be neglected at the time and I am of opinion that in all such cases where the symptoms can be localised and an injury can be traced to the same region, although apparently not severe, an exploratory trephining operation should be made as likely to reveal pathological changes.

In the following case the symptoms of severe mental depression and a transient attack of word blindness enabled me to conclude that the disease was originally limited to the neighbourhood of the supramarginal and angular gyri, and that it had subsequently spread downwards over the posterior temporal area, judging by the symptoms of irritability and delusions of suspicion, whereof we have a hundred cases on record in which the disease was confined to this region Finding on enquiry that this part had been actually injured, though there was no outward visible sign, I felt certain that pathological changes would be discovered on trepannation, and advised operation to which the patient, himself an experienced physician, readily agreed. The result, as will be seen, was in every way satisfactory.

J. L. D. M., doctor of medicine, æt. 39, negative family history, no previous illness, received a kick from a horse on right side of chin in 1898, followed by severe frontal headache and neuralgic pains. A year later he had a heavy fall from his cycle on the right side of his head, leaving no visible signs of injury, but followed by hemicrania of great severity, preventing any intellectual work, and by definite character changes. He became emotional, anxious, very depressed, accused himself of unpardonable sins, developed suicidal ideas, grew suspicious, easily offended, irritable and profane, erotic and subject to uncontrollable fits of sexual excess. He suffered also from obstinate constipation, persistent insomnia, and had sensory disturbances in left arm. He sought relief in change of scene by travelling, but to no effect, and his strange conduct frequently led him into difficulties. In Spring, 1905, he had symptoms of word-blindness, and a transient attack of paralysis of right side of face and left half of body. The depression and headache increased and all medical treatment failed to cure him. Believing in the possibility of localisation of mental functions, and hoping that, if his symptoms were localisable, operation would show pathological changes and give relief, he came to London.

On examination, on October 3rd, 1905, he appeared depressed, emotional, showed strong suicidal tendency, and complained of intense headache on right side, and a burning sensation just posterior to right parietal eminence.

October 9th, 1905.—Operation by Mr. William Turner, M.S., F.R.C.S.; chloroform anæsthesia. When the head had been shaved, a scar became visible 2 inches behind right ear, 2 inches long, commencing behind parietal eminence in the situation of the angular gyrus and extending vertically downwards corresponding to the posterior part of the temporal convolutions. A semi-circular flap was made, extending from the tip of the ear to the occipital protuberance. The scar tissues were found firmly adherent to the bone, and had to be forcibly detached. Two trephine openings were made, one 1 inch in diameter, and the other 11-16 inch, just below, and a little behind the other, and joined together. The bone over the angular gyrus was found thickened and hardened, with scarcely any diploe, and the dura mater was adherent to it. When the bone was removed, the dura mater bulged into the opening, but showed no signs of pulsation, although the pulse of the patient at the time was quite strong. On cross incision of the dura mater a stream of clear fluid escaped. The membrane was opaque and thickened, but the brain appeared normal, and on examination the neighbouring parts revealed no pathological changes. The dura mater was stitched together and the periosteum over it, the portion of bone not being replaced. A drainage-tube was kept in scalp-wound for three weeks. Patient during this period had still occasional attacks of depression and irritability, headache and trigeminal neuralgia, but with the closing of the wound all symptoms disappeared.

November 15th, 1905.—Wound quite healed. Trephine openings felt through scalp. Brain felt pulsating beneath, but no protrusion. No tenderness of surrounding nerves. General condition quite well.

February 20th, 1907. Patient reported himself as absolutely well both mentally and physically. The only trouble he had had since the operation a year and a half ago was a severe attack of colitis, which had no relation to the original brain trouble. In his own words, he feels his former self as before the accident in 1898. Moreover there has been no return of the insomnia, the severe headache and the neuralgic pains, from which he had suffered for a period of eight years. The attacks of mental depression, his morbid suspicion and all suicidal thoughts, the erotic feelings, and morbid sexual symptoms have likewise entirely disappeared, and he has resumed interest in all the affairs of life. Surgically the head was perfect in appearance and there was no tenderness anywhere.

THE MEDICAL TREATMENT OF GASTRIC ULCER.

By S. A. ARANY, M.D.,

Consulting Physician at Carlsbad.

The progress and development of surgery made it possible that cases of gastric ulcer and its complications, which have been considered as fatal in former years, are amenable to surgical treatment and recovery. It is undeniable that numberless people owe their life to the skilful and timely intervention of the surgeon's knife, but, on the other hand, there is very little doubt as to the fact that many a surgical intervention, however skilfully performed, has accelerated the patient's death, who, under proper and carefully prolonged medical treatment, could have enjoyed his life and fairly good health for many years to come.

It is not very long since the operative treatment of appendicitis has been introduced, and nowadays its employment has become so universal that medical treatment of that ailment has almost gone out of fashion. I say medical treatment has gone out of fashion, as it is fashionable to recommend a patient who suffers with some symptoms of appendicitis to undergo an operation whether there be immediate necessity or not. Now, in one-third of the cases the surgeon reveals that there was nothing the matter with the appendix; in another the conscientious surgeon may find the appendix in a condition that would have improved with less risk under a proper medical treatment; and finally, in the last third of the cases the surgeon will find that his intervention is really wanted.

I consider it just as grave a mistake to send a case in which medical treatment may be successfully employed under the surgeon's knife as to hesitate with the operation in a case in which medical treatment proved to be of no avail.

I look upon the operation of appendicitis as an *ultima ratio*, and am of the same opinion as far as gastric ulcer is concerned.

The operative treatment of this latter disease is also very much in vogue, and the profession resort to it much oftener than needful. It ought to be looked upon as an *ultima ratio*, and its indications, which I beg to give in the following, deserve to be well considered :—I only avail myself of the surgeon's help: If the patient's life is in danger (1) through fulminating hæmorrhage which cannot be arrested; (2) through perforation; (3) inanition caused either by the fact that the ulcerated stomach cannot retain any food, or by contraction and adhesions

I have lately read a good many papers advocating surgical treatment in preference to medical treatment, and some of the authors even went so far as to state that medical treatment effects only in 25 per cent. of the cases a cure.

This is a very small percentage, indeed, and I cannot account for it under any consideration, unless I am to suppose that the cases referred to have been a collection of unusually severe cases. For well-known clinicians as Leube, Ewald, and Cohnheim's statistics average between 50 and 70 per cent., but as many of their patients comprise hospital patients who cannot always be depended upon, as, after their leaving the hospital, we very rarely know how they were getting on, I beg to quote my statistics, and shall confine myself to cases of whom I hear from time to time, not taking into account such cases as I have seen once or twice in consultation.

The number of my cases is eighty-two, all of whom I have known from two to ten years. Out of the eighty-two eleven have died from the following diseases:—Six died from cancer, after having enjoyed from four to seven years' fairly good health after their treatment for gastric ulcer; two have been operated upon for hæmorrhage twelve and sixteen months respectively after their treatment, and died soon after the operation; one died of perforation, one of diabetes, one of apoplexy.

The remaining seventy-one are enjoying fairly good health; of course, some of them have to live carefully and are in need of some treatment from time to time; but do patients on whom a gastro-enterostomy has been performed do differently? Is it the rule, or is it the exception, that robust health of a normal constitution has been restored by the operation?

If medical treatment is not always successful there are principally three reasons which account for it: (1) Late diagnosis; (2) wrong treatment, under which heading I also comprise treatment which has not been continued for a sufficiently long time; (3) carelessness and disobedience on the patient's part.

The Diagnosis of gastric ulcer is not quite so easy as our text-books have taught us. We have learnt in school that in gastric ulcer the patient complains about violent pain in a localised spot, which occurs almost immediately after meals. The pain is localised in the right hypochrondrium, and is in most cases followed by vomiting. But in what a cluster of diseases do these symptoms appear? Don't we meet them in ordinary gastralgia, nervous dyspepsia, gall-stones, and nephrolithiasis? Doesn't the primary stage of cancer show the same symptoms? But the text-book points out two more very important symptoms, namely, hyperchlorhydria and hæmatomosis. As far as the first is concerned, it is a symptom on which in a great majority of cases we can depend but it cannot be looked upon as a *conditio sine qua non*. According to Ewald's investigations, only in 34 per cent. of his cases was hydrochlorhydria present, whereas in 57 per cent. the acidity was normal, and in 9 per cent. the acidity was found to be sub-normal. Out of my eighty-two cases the acidity was tested in sixty-eight cases, out of which latter in sixty-three cases hyperchlorhydria was established, and in the remaining five the acidity was normal. Hæmatomosis is very often the only symptom which raises the practitioner's suspicion as to the nature of the disease, but it is of quite frequent occurrence that hæmorrhage remains unobserved, as in many cases the amount of blood is very small, and in other cases vomiting does not take place, and the fæces are not paid attention to.

Palpation is but of secondary importance; it very rarely reveals the seat of the ulcer, and owing to the hyperæsthesia of the patients, very often misleads the examiner.

If the text-book doesn't supply us with all the information we want, practise teaches us that a patient suffering from gastric ulcer is very rarely so emaciated and cachectic as a sufferer from cancer; he also recuperates very soon after the acute symptoms have left him, and enjoys, in contrast to the latter, a very good appetite, has a clean tongue, and no nasty taste in the mouth, as is usually the case in dyspepsia and cancer. The fear of food, in contrast to the loathing of food in other stomach troubles, is also very characteristic in gastric ulcer. These and several other little things must guide the practitioner in making a diagnosis, in which case diagnostic errors and ill-effects from medical treatment will not be experienced.

Treatment.—In the acute stage of the disease the patient must be confined to bed for eight or ten days. Absolute rest will best alleviate the pain and hæmorrhage. For the latter I usually employ the ice-bag and make the patient swallow ice. This usually stops the hæmorrhage; should it prove insufficient, a hypodermic injection of 1 c.c. of a 0.1 per cent. solution of adrenalin will in most cases stop the bleeding. Instead of the ice-bag, Leube and others recommend hot applications, which I prefer to use in the second stage of the treatment. Very effective is the administration of magistery of bismuth, first recommended by Matthes, and chiefly advocated by Kussmaul and Ewald. The latter recommends as large doses as 20 grammes per diem; he prescribes the drug in a watery solution to be taken in three portions. The drug is to be taken for a protracted period, and Ewald never noticed any ill effect even if 600 or 800 grammes have been consumed. Matthes' object in administering the bismuth is that the latter forms a coating round the stomach wall and protects it from further injury.

With the same object Cohnheim prescribes his oil-treatment, but the oil is not so well tolerated as the bismuth, although its action on the hyperchlorhydria is undoubtedly beneficial, and has, if anything, a high nutritive value.

I remove the ice-bag on the third or fourth day and replace it by cold compresses which are changed every hour. On the same day, the patient, who has hitherto been fed by the rectum, gets small quantities of milk (preferably cold, boiled milk in the first few days). Or if the latter is not tolerated, bouillon. The amount of milk or bouillon must not exceed two pints per diem in the first three days of alimentation per os, and all we can add is a raw egg or two, which must be well beaten up in the milk or bouillon, and is mostly well tolerated by the patient.

At the end of the first week the patient is put on a mild Carlsbad treatment, as first prescribed by Leube. The latter gives his patients a tumblerful of luke-warm Muhlbrunn, which decreases the acidity of the stomach and also acts as a mild aperient. I prefer to administer the Muhlbrunn fairly hot—about 140° F.—and give the patient three wineglassfuls in the course of two hours. Now the quantity of milk may be increased, and porridge and soft-boiled eggs may be added. As a rule, on the tenth or twelfth day the patient is quite relieved of pain and feels fit to leave his bed. As soon as this stage is reached I increase the amount of Carlsbad water to three tumblerfuls a day, and in cases of constipation add a teaspoonful of Sprudel salts to the first tumbler. This goes on for from four to five weeks, and in the three weeks of treatment I replace the compresses by a termophore, to be employed during the night. Dietary concessions must also be made, as the patient will now possess a good appetite and require some solid food. This, however, must be done very carefully, as many a relapse has been caused by an over-generous diet. I wish to emphasize this fact, as latterly a certain part of the profession in Germany is rather in favour of a generous diet even immediately after the hæmorrhage, intending thereby to increase the patient's power of resistance. How risky this theory is it is needless to explain, and my general rule is to keep the patient on milk, porridge, rice pudding, fish, fowl or greens for at least two months, and even afterwards to advise him to abstain from beef, pork, game, pastry and bread. This latter, in any shape, is very badly tolerated, and should be replaced by gluten biscuits.

For the anæmic condition of the patient I prescribe, in preference to the usual preparations, the Levico water, containing iron and arsenic in such quantities as are easily assimilated by the patient, availing myself of the *stronger* spring, and start with a tablespoonful after each meal (*i.e.*, three tablespoonsful a day); at the end of the first week two tablespoonsful, and at the beginning of the third week three tablespoonsful, are administered three times a day. Then I decrease the dose by a tablespoonful each week, and recommend a fortnight's pause, after which the patient undergoes a second course. This usually suffices to improve the anæmic condition and the patient's nutrition in general, as I advise to take the Levico water in milk.

Now the question of spa-treatment has to be considered, and authors are unanimous in recommending Carlsbad in these cases. It is not only on account of its alkaline-saline springs, which are undoubtedly a very important healing agent in the treatment of gastric ulcer that Carlsbad is to be recommended; the dietary conditions speak just as much in its favour. Patients having recovered from the acute symptoms of gastric ulcer must be very careful as to their diet, and cannot be left at large. They must be under certain restrictions, and must not be given a chance of breaking the rule. The dietary conditions in Carlsbad are just adapted to this, and contribute to a great extent to the excellent results obtained there. For an "after-cure" the patient is best sent to the mountains or to the sea, and if he continues to exercise care it is very unlikely that he will experience a relapse. This is the course I adopted in all of my cases, and the result obtained was more than satisfactory.

CLINICAL RECORDS.

TWO CASES OF "MISSED ABORTION."

By JAMES DUNLOP, M.B., C.M.

Formerly Assistant Physician at Glasgow Royal Infirmary.

Case I.—Mrs. H. F., æt. 22, married on 6th September, 1895, was menstruating at the time. Again altered on 1st October and 1st November, and ceased in December and January, 1896. She believed herself then to be pregnant, and was alarmed when on February 7th she seemed to alter again.

I first saw her on February 8th, and treated her for a threatened miscarriage, but made no *per vaginum* examination. In three or four days the discharge stopped (it was not more in amount than her usual menstrual discharge), and she remained ten days in bed.

She was a rather anæmic and nervous but quiet woman, and engaged me to attend her confinement, which was calculated for August 20th. In March no discharge occurred; but on April 14th a slight discharge again came on, and I was asked to see her. Two days later I called and examined her, as she did not look like a woman five months pregnant. I could not get a very good chance of a bimanual examination, and declared to her that in my opinion she was not pregnant at all, or, if so, that she was certainly not five months pregnant. I prescribed some iron tonic for her anæmia and allowed her up.

I did not see her again until I returned from my holidays in August, on the 29th of that month, when I got the following story: In May and June she had an imperfect menstrual period. In July she altered for one day. On August 19th she was sick and vomiting, and had severe diarrhœa, and a little red vaginal discharge with sore legs, and thought she was going to alter.

About 1 a.m. on August 20th (curiously enough the day of her expected confinement), she had severe colicky pains in her abdomen, and was seen by my Locum tenens (Dr. Archie Young), who gave her a sedative draught. She thought it painful menstruation, but about 12 noon on August 20th she had a miscarriage—the specimen before you, which came away entire and was preserved in spirit for me by Dr. Young.

I was now confronted with the awkward fact that I had in April declared my belief that she was not pregnant. My answer was that she might have become pregnant after that date, as the ovum did not look more than three months size, and now the whole truth came out.

When I told her on April 16th that I did not think her pregnant, and that the irregular menstruation was probably due to her anæmia, her mother took her to another doctor (since deceased), who examined her at the end of April or beginning of May, and likewise declared his belief that she was not pregnant, but advised that she should have no sexual intercourse for some time, and she declares that from April 16th when I saw her, till September 1st, when I got a detailed history from her, she had no marital intercourse (I have no reason to disbelieve her statements), and that the miscarriage of August 20th must have been lying in her womb previous to April. The probability is that the ovum died in February, when she had the first hæmorrhage; but the measures taken to prevent the miscarriage had been too successful, and kept the uterus quiet in spite of the ovum having died.

Case II.—Mrs. J. C., æt. 37, fourth pregnancy, last menstrual period in end of March, 1905. Had some bleeding in the end of June till July 5th, when I was asked to see her, and advised her to remain in bed. She was three weeks in bed, and had a little bleeding occasionally all the time. When it ceased she got up, and saw nothing for two weeks, when she again had a little discharge for two days.

She kept all right till end of October (a day or two ill then). On Christmas week there was a good deal of discharge for three days. It stopped again till January 3rd, when it again commenced, and on January 5th, 1906 (the date of expected confinement), after some hours of pain, this specimen was passed entire. Her breasts got smaller after July, and she went to Millport for a fortnight in September. In October I told her it was a "missed abortion," but advised her to wait on nature bringing on her pains as she had no discomfort and continued at her daily duties up to the new year. I curetted uterus the same day that the ovum was discharged, and she made a very good and rapid recovery.

OPERATING THEATRES.

KING'S COLLEGE HOSPITAL.

EXTENSIVE HÆMATOMA OF THIGH AND LEG.—Mr. PEYTON BEALE operated on a youth, æt. about 14, who had been admitted two days previously suffering from a contused wound on the outer side of the right knee, together with a very extensive swelling occupying practically the whole of the thigh and leg from the apex of Scarpa's triangle to the ankle. It was certain that a wheel of a van had passed over the boy's leg, but there was no evidence to show exactly where or in what direction. There was pulsation in the femora and popliteal arteries, but none in either the anterior or posterior tibial; it was therefore assumed that the poplital had been ruptured just above or at its division into anterior and posterior tibial, and it was also evident that the swelling of the leg and thigh was due to an enormous hæmatoma. Immediately after admission the temperature rose to about 101°, and varied between 100° and 102° for the next two days; this temperature, it was assumed, was due to absorption of fibrin ferment only. On the third day multiple incisions were made in the skin of the thigh and leg; an enormous quantity of dark liquid blood and blood clot was washed out with an irrigator. It was now seen that the whole of the skin was stripped away from the deep fascia of the thigh and leg, and that in the region of the popliteal space there was a considerable amount of blood-clot between the muscles and tendons. Much of the fat of the superficial fascia was necrosing, and where it presented in the skin incisions it was found rolled up into small masses looking exactly like pieces of omentum, such as are found in strangulated omental hernia. As many as possible of these pieces of fat were removed and gauze drains were inserted into each incision. During the following week a very considerable amount of skin sloughed away, commencing with the bruised part on the outer side of the knee. Investigation showed that the sloughing was aseptic except where the contused wound had been, and here there was a localised sepsis, quite small in extent. The temperature remained between 100° and 102°, and later on was gradually getting higher. Some dulness in the region of the spleen was observed, but there was no evidence pointing to any extensive thrombosis in any of the veins. Dr. Dalton, who kindly saw the case, pronounced the chest normal, and was unable to find any distinct evidence of splenic infarct or endocarditis such as might account for the rise in temperature. Mr. Beale remarked that it was at present quite impossible to account for the rise of temperature which was proceeding; there was no evidence to show that any septic trouble was in progress, and he could only conclude that there must be some thrombosis going on in one or more deep veins. It was fairly certain, he said, that the wheel of the van had passed obliquely over the leg, knee, and thigh, and in all probability the popliteal vein as well as the artery had been ruptured.

HÆMATOMA OF THE ABDOMEN.—The same surgeon was asked to see a youth, æt. about 16, who had been operated on by one of his colleagues three weeks previously for suppurative appendicitis; at the operation there had been a considerable amount of hæmorrhage from a vessel in the appendix mesentery; within the last few days a large and firm tumour had been forming in the left side of the abdomen and pelvis and the temperature had been steadily rising, so that it became necessary to explore the abdomen in order to ascertain the cause. On making an incision over the tumour, it became at once apparent that the latter was a very large intra-peritoneal hæmatoma, and from the odour of the blood when exposed it was quite clear it was infected with the bacillus coli, and was just on the verge of breaking down to form a large abscess. The blood and clot were freely removed and the cavity irrigated with hot sterile salt solution, and a large gauze drain inserted. Mr. Beale remarked that many of the cases of suppurative appendicitis in which abscesses were found some weeks afterwards in the left side of the abdomen were caused by suppurating hæmatoma, the infection being the bacillus coli.

TRANSACTIONS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, APRIL 12TH, 1907.

MR. CHARLES SYMONDS in the Chair.

MR. LAWRIE MCGAVIN read a paper on

A MODIFICATION OF THE METHOD OF APPLYING PREPARED FILIGREES OF SILVER WIRE TO THE CURE OF LARGE INGUINAL HERNIA IN MALES.

MR. MCGAVIN referred to the difficulty at present experienced in attempting a cure in cases of very large or recurrent inguinal hernia. The frequency of recurrence of hernia, even after operations in skilled hands, and the success met with in dealing with very large abdominal hernia by Bartlett's method, had led him to modify that method of filigree implantation to meet the requirements of hernia in the inguinal region, the object in view being the establishment of an operation which should justify the term "radical cure," and do away with the use of any form of truss. The method he had adopted was that of utilising two separate filigrees, an iliac and a pubic section, of special pattern, for the purpose of defending the whole inguinal region without the sacrifice of the testis and cord. The pubic section was placed upon the peritoneum between the internal abdominal ring and the pubes; the posterior wall of the inguinal canal was then re-made over this by Bassini's method, the conjoined tendon being sutured to Poupart's ligament. The cord was then laid in position, and the transversalis and internal oblique muscles being incised outwards towards the iliac spine, the peritoneum was peeled back from their deep surface; a bed was thus provided for the iliac section which was placed on the peritoneum in such a manner that its inner third lay upon the cord at its exit from the internal abdominal ring, overlapping for a distance of threequarters of an inch the outer end of the pubic filigree. The divided muscles were then united over this iliac section, and the aponeurosis of the external oblique muscle was closed over the whole area as far as the external abdominal ring. The results in all the cases done had been entirely satisfactory. In all of these cases, although quite beyond the scope of the ordinary operation, the method had produced an inguinal region so firm and hard that no truss or support of any kind had been worn since the time of operation, nor did it appear possible that any yielding of the scar could take place. In no case had any complication referable to the presence of the filigree arisen, nor had any of the filigrees to be removed. Pain and discomfort were entirely absent. The author had now adopted the method described as a routine practice in all cases of recurrence, and in all cases of very large hernia.

MR. WALTER G. SPENCER thought that Mr. McGavin's suggestions constituted an important advance in surgical technique. There was no doubt that Bartlett's method was of the greatest value in the management of large abdominal hernia. He related the details of a difficult case of this condition he had recently to deal with.

DR. DOUGLAS DREW congratulated Mr. McGavin on his excellent results. He had used filigrees in several cases of large ventral hernia, and in one case, in a woman, of inguinal hernia. He thought it was not necessary to remove the filigree even if fluid collected and had to be let out. The filigree method was far superior to the device of darning with silver wire that was often adopted, because it was so much quicker.

MR. A. E. BARKER had had no experience with filigree, but considered it might be of great value in bad cases. He had obtained excellent results in a large number of cases treated with the darning method, which, though tedious, had the advantage that one was not beforehand restricted to the extent and variety of procedure to be adopted.

Mr. McGavin, replying to a remark of Mr. Spencer's, said that one advantage of the Bartlett method was that no pad or truss of any form need be used afterwards. As to the size of the filigree, it was better to use one too large than too small, for in the latter instance there was a hypothetical possibility of recurrence.

Mr. W. G. Spencer described a

CASE OF SOLITARY ACUTE SUPPURATION IN THE PSOAS AND ILIACUS MUSCLES,

which occurred in a quite healthy boy, æt. 13. The boy died four days after the onset without being relieved by the incision made the day before. There had been no history of strain; the pus yielded a pure cultivation of staphylococcus pyogenes aureus; the only lesion found after death was the acute suppuration in the right psoas and iliacus muscles; everything else was found normal; there was no distant septic focus. Apart from the cases arising by extension from the uterus, appendix, spine, &c., there were a number on record, in which a slight strain along with some distant septic focus, such as chronic otorrhœa, has occasioned acute and fatal suppuration. In other such cases the distant septic focus has been apparently the cause without any strain, and again in others a strain has proved sufficient without any distant septic focus being revealed at the post-mortem. Both the above antecedents had been absent in Mr. Spencer's case. At present there appears to be no sufficient explanation of cases, which, to judge by the number on record, form a distinct affection.

Mr. Charles Symonds had seen two cases that recovered. He thought the best explanation was that of a general infection. He related a case of this that manifested itself locally in the pectoral muscle though a very slight injury of this.

Mr. Drew said that impetigo was an occasional mode of entry of such infections in children.

Dr. De Havilland Hall related three cases of abscess of muscle, in which there had been great difficulty in diagnosis.

Dr. Essex Wynter said that a number of cases existed in foreign literature. He detailed a case that had run a typhoid course, and which after death had been found to be one of suppurative psoasitis, the organism being bacillus pyocyaneus.

Mr. Gordon Watson likened the cases to acute osteomyelitis. He related two cases of staphylococcic psoasitis occurring during the puerperium, apparently apart from parametritis.

Mr. McGavin discussed the anatomical reasons why the psoas was so frequently selected for these occurrences.

Mr. G. H. Makins and **Mr. Percy Sargent** read a note on the

VALUE OF THE ANTI-COLON-BACILLUS SERUM.

The paper contained a tabular statement of the histories of 25 cases of acute appendical peritonitis treated by injections of a multivalent serum prepared from different strains of bacillus coli communis. The serum had been prepared by Dr. H. H. Dale, of the Wellcome Research Laboratories, at the instance of Dr. L. S. Dudgeon, by the following process. A horse was immunised by receiving fourteen injections of 10 c.c. of seven days' broth culture of eight strains of bacillus coli from cases of puerperal fever, at intervals of seven days; seven injections of 5-20 c.c. of a washed culture of B. coli of unknown origin, at intervals of 10 days; one injection of 5 c.c. of three weeks' growth in lactose broth of seven strains of unknown origin; seven strains separated by Dr. Dudgeon from cases of peritonitis; and eight strains from cases of puerperal fever. In all cases the cultures injected were killed by the addition of 0.1 per cent. chinosol. The twenty-five cases were of the severe type, six of them probably being such that no good effect could be anticipated. Of the whole twenty-five, nine, or 36 per cent. recovered. In all the others improvement followed the use of the serum, toxic symptoms were relieved, localisation of the infecting area was effected, and in cases that died the end was delayed considerably beyond the period usual in the disease. It was claimed that the general improvement in the patient's comfort, the sequence of quietude or sleep, a definite fall in the pulse-rate and temperature (either temporary or continued), and the relief in many cases from vomiting, obtained by the use of the serum justified its more extensive trial. The results appeared to prove that the treatment exerted a definite curative influence on the disease, and that it was in no way harmful or dangerous. A successful case of treatment of an acute infection of the urinary tracts by colon bacillus, under Dr. H. G. Turney, by the use of the serum, and a report on the treatment of three cases of puerperal sepsis by Dr. A. K. Gordon, of Manchester, were also alluded to.

Dr. Leonard Dudgeon thought the serum of very great value, provided it was used early enough. It was without action, however, in the chronic cases with no constitutional symptoms.

LIVERPOOL MEDICAL INSTITUTION.

Meeting Held Thursday, April 4th, 1907.

Mr. Frank T. Paul, F.R.C.S., President, in the Chair.

SUPPURATIVE CHOLECYSTITIS.

Mr. T. C. Littler Jones read a note on suppurative cholecystitis, with perforation of the gall bladder, mentioning three cases under his care which had recovered. In one case the gall stones, after perforation of the gall bladder, had collected in a large perinephritic abscess. This abscess had then opened into the pelvis of the kidney; some of the stones being passed out of the body through the urinary tract, others being removed from the kidney at the time of the operation. Some of the stones were partially encrusted with a deposit of phosphates. The other cases were acute, and in both after the peritoneum had been cleansed, the gall-bladder, the site of the perforation, and the abdominal incision were each separately drained. He attached much importance to early diagnosis, to the method of draining, and to the way in which the gall bladder was stitched to the abdominal parietes, attempting where possible to have the edges of the incision into the gall bladder invaginated in order to facilitate the early closing of the biliary fistula.

BENIGN CYSTS IN LONG BONES.

Mr. Robert Jones and **Mr. David Morgan** read a note upon benign cysts in the long bones and reported four cases, three of which appeared in the proximal phalanx of the index finger and one in the centre of the ulna. After referring to the literature an attempt was made to simplify the differential diagnosis both by differences in X-ray appearances and by other clinical signs.

THE ROLE OF MERCURY IN MODERN THERAPEUTICS.

Dr. Wm. Carter, in his paper on the above subject, did not include any consideration of the employment of the drug in the treatment of syphilis. He thought its use was neglected, and mentioned (1) cases of lymphatic block with enormous swelling, but no escape of fluid through Southey's trocar; (2) peritonitis; (3) of cerebral meningitis, even when suspected to be tubercular; (4) of chronic cardiac disease when death appeared to be imminent—in all of which the free use of mercury either internally or by inunction, and in meningitis accompanied by blistering of the scalp, was followed by relief, and where the organic changes were not such as to render recovery impossible, by recovery. Five cases were mentioned of the control of the delirium which sometimes accompanied rheumatic fever, and of the persistent headache of robust men in whom there was no fever by 5grs. of calomel, even though the purgative effect were less than that produced by other cathartics. He showed three bottles, in one of which bile alone had been kept for ten days; in a second, bile with 2½ grs. of calomel, and a third in which calomel had only been added to the bile after the terribly offensive odour which characterised the contents of the first bottle had been developed; and asked if the freedom from, and correction of, decomposition in the two latter might not possibly help to explain the utility of the drug. Its insolubility allowed it to be conveyed to the duodenum unchanged, where it came into contact with the bile and pancreatic, fluid, over which latter it could be shown to exercise a similarly antiseptic action; and it was not unreasonable to suppose that absorbable toxins were so influenced by it as to be rendered harmless.

Dr. F. H. Barendt regarded mercury as second only in importance to opium, and in cutaneous medicine, apart from syphilides, mercurial preparations were among the most valuable in treating chronic skin diseases. He extolled the use of Unguenti hydrargyri, subchloridi linimenti hydrargyri, and Unguenti hydrargyri iodidi rubri in brawny infiltration as a result of chronic eczema. Internally the alterative action of mercury could scarcely be over-estimated, and he drew attention to its administration in psoriasis after the eruption had been removed by external medication, as a prophylactic against recurrence. He quite agreed with Dr. Carter that it was most important to give exact instructions to the patient even at the risk of stating the self-evident.

Dr. Sumner considered that the intestinal antiseptic property of mercury was indirect, being in a great measure attributable to the increase in the output of bile, which acted as the best of all intestinal antiseptics.

Dr. S. Kellett Smith drew attention to the danger of administering mercurials to feeble old people with septic mouths. In such cases dangerous salivation might ensue from even single doses of calomel or blue pill. He had found phenolphthalein in 8 grain doses a good purgative when there was reason to fear any ill-effect from a mercurial.

Dr. J. Lloyd Roberts referred to the benefit derived from the occasional use of mercurial preparations in the treatment of chronic valvular disease of the heart, where failure of compensation was threatening.

Dr. T. R. Glynn, Dr. Bennet, Dr. E. T. Davies, and Dr. Chas. J. Macalister also took part in the discussion.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

CLINICAL MEETING HELD FRIDAY, APRIL 5TH, 1907.

The President, Dr. Leonard Mark, in the Chair.

The following cases were shown:—

Mr. Aslett Baldwin: Disseminated sclerosis following injury. Tabes with opthalmoplegia and epithelioma of the tongue.

Mr. Laming Evans: True traumatic flat foot due to dislocation between the astragalus and the scaphoid.

Dr. Fry: Endothelioma of the tonsil.

Dr. Rice Oxley: Tumour of the neck.

Dr. F. S. Palmer: Facial palsy in a child of three months. Disseminated sclerosis following injury.

Dr. Chisholm Williams: Lupus of the nose treated by X-Rays. Epithelioma of the nose treated by X-Rays. Recurrent carcinoma of the breast treated by X-Rays.

Dr. Andrew Wylie: Cases of laryngeal paralysis.

The cases were discussed by Mr. Percy Dunn, Mr. D. Armour, Mr. Percy Paton, Dr. G. Alderton, Dr. Buttar, and others.

Cancer in Essex.

Dr. Thresh, Medical Officer of Health for Essex, has reported to the Essex County Council that the mortality from cancer in the county was increasing yearly. He predicted that at the present rate of increase cancer in a few decades would cause more deaths than any other disease. It was decided to ascertain, if possible, the relationship, if any existed, between cases reported and pre-existing cases.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, April 15th, 1907.

Treatment of Uræmia.

Hitherto uræmia has been considered the result of the accumulation in the blood of urea, uric acid, extractive and colouring matter of the urine, &c., but at an advanced period, at least, of the affection, certain substances such as the chlorides are found to be in insufficient quantities in spite of the milk diet, and even disappear completely.

This phenomenon, remarked formerly by Mehu, was the object of close clinical study by Professor Huchard, some time ago, when he showed its importance as regards the prognosis of the malady as it signifies, generally, approaching death. When this fact is apprehended chloride of sodium must be furnished without delay by the mouth, enemas, and subcutaneous injections.

The physician, says Dr. Huchard, should not wait for the ultimate symptoms of uræmia—convulsions, coma, Cheyne-Stokes dyspnœa, as it might be too late; he should be ready to act on the first symptoms—dyspnœa, resisting the exclusive milk diet, and a certain pallor of the integument from vaso-constriction, generalised muscular asthenia attributed too frequently to the milk diet.

The treatment should consist of three irrigations—that of the stomach, the intestines, and the blood.

Irrigation, or washing out of the stomach, is one of the most difficult to make acceptable to the patient. But the attendant must impose his authority and insist on the necessity of the disagreeable operation. Frequently the stomach contains an excess of acid and consequently a quantity of very virulent toxines. The liquid to be employed may be Vichy water or artificial serum.

The intestine should be thoroughly washed out by means of a long soft catheter. Two quarts of boiled water, to which are added 4 drachms of chloride of sodium, should be injected two or three times a day.

Irrigation of the blood is obtained by injecting subcutaneously into the cellular tissue from 6 to 20 ounces of artificial serum, repeated twice or three times a day. These injections increase the arterial tension, favour diuresis, and introduce into the organism a considerable quantity of serum.

Besides the above, which forms the essential and almost exclusive treatment of uræmia, purgatives might be given and sometimes blood-letting might precede the subcutaneous injections. Drugs called "antiseptics" are of but little use.

Treatment of Warts.

The common warts, or dermo-epidemic excresence, are observed in young subjects on the fingers, back of the hands, or feet, and sometimes in other regions of the body. They appear to be due to the presence of the bacterium porri (Cornil); they are auto-inoculable, and multiply abundantly. Any acid is good for their destruction—nitric, acetic, hydrochloric, chromic acids, or the thermo-cautery.

Slight cases may be successfully treated by the application of black soap. A thin layer of soap is spread on a piece of linen and wrapped around the hand each night. In the morning the parts are washed in warm water to remove the soap, and powdered with talc or oxide of zinc.

Where the application of soap causes too much irritation of the skin, it may be replaced by the following preparation recommended by Kaposi:—

Flowers of sulphur, drs. 5.
Glycerine, ozs. 2,
Acetic acid, drs. 2.

This paste is especially employed for the numerous warts of the back of the hands and of the face.

Different preparations of collodion are frequently used:—

Salicylic acid, grs. 15
Collodion, drs. 2

Or,

Corrosive sublimate, grs. 4
Collodion, drs. 2

This latter is very irritating to the skin and should be applied with care.

Juvenile sessile warts form colonies on the face, back of the hands, and wrists. Their treatment require more prudence than the ordinary common warts on account of the extreme irritability of the skin in young subjects. The superficiality of the lesions excludes the employment of caustics. According to Professor Du Castel, applications of black soap or ointments of salicylic acid and resorcin are sufficient, but even these should be suspended as soon as the skin shows more or less redness.

Senile warts are generally observed after age 50, and appear on the face, neck and body. They belong to the class of *noli me tangere* of the ancients, yet it is always good practice to remove them, as they frequently represent the first step towards epithelioma. They should be treated in the same way as the common wart.

The effect of medical or internal treatment of warts is very doubtful and many dermatologists place no confidence in it. However, calcined magnesia in small doses continued for weeks has been said to have been successful.

The tincture of thuja accidentalis has been recommended in 20 drop doses three times a day.

Nocturnal Erections.

Bromide of potassium, grs. 40
Lupulin, grs. 20
Sugar, grs. 10

For one wafer; to be taken at bedtime.

GERMANY.

Berlin, April 14th, 1907.

At the Verein für Innere Medizin, Hr. Boenrainger related a case of

Death After an Exploratory Puncture.

A woman, æt. 80, was brought into the Klinik with a diagnosis of pleurisy. There was cardiac weakness along with bronchitis; examination showed dulness below and to the left, with lessened pectoral fremitus. A pleuritic effusion was suspected, and an exploratory puncture was made by an assistant in the seventh intercostal space, about 8 cm. from the vertebral column. Immediately after the puncture the patient gave a violent cough, expelled some bright red blood mixed with mucus, and died in a few minutes with symptoms of suffocation. The autopsy showed a slight injury of the pulmonary pleura. There was no exudation in the pleural cavity, and only a little blood; the left lower lobe of the lung was empty of air, much reddened and containing blood in the bronchi. The needle on entering had penetrated a dilated vessel and a bronchus, the blood had flowed into this, and the patient in her weak condition had been unable to cough it up, and succumbed to its suffocating effect. The case shows that even an exploratory puncture is not free from danger.

Hr. Goldscheider spoke on

Psycho-reflex Symptoms of Disease.

He said that the reflex seemed to be a quite simple affair. From the data acquired by the physiologist, one had constructed diseases from the reflexes—reflex diseases, reflex symptoms. Now we saw that a part of these symptoms—involuntary expressions without conscious feeling—did not correspond to the degree of the reflex, but that a portion were due to the action of the consciousness. Thus in coughing, a conscious sensation played a part, the tickling excited the reflex of coughing, but the giving way to it depended on the will. It was the same with vomiting. That did not take place after a purely reflex manner, but chiefly and principally by the repugnant feeling that some foods caused. Such processes the speaker designated "psycho-reflexes," since, for example, in the case of cough, the psychic force could keep back the expected irritation. On the other hand, the expected irritation could pave the way for the reflex. The sexual reflexes also were prepared by psychical impressions. The involuntary spitting out from the mouth of objectionable things that had got into it, belonged to this category. These automatic movements were very frequent, like the fidgets of neurasthenics, from any uncomfortable sensation. Further external excitants called up images and recollections, and these led to automatic movements.

This was the case of all external excitants that set up reflexes. Corresponding to this we found, in the case of internal diseases, the state of feeling that was associated with it. Normally, we felt nothing of our internal organs; every sensation, the effect of disease, caused a disagreeable sensation that called up reflexes. So the baulking movement that accompanied washing out of the stomach was not purely reflex, but partly voluntary, with a view of relieving the disagreeable sensations. The tone of feeling was accompanied by other bodily changes as in changes of respiration of the pulse of blood preparation. A series of so-called symptoms were automatic, such as coughing, eructating, &c. Internal excitations were but excesses of reflex preparation.

These considerations threw light on the powerful influence of psycho-therapeutics in bodily diseases.

At the Freie Vereinigung der Chirurgerie, Hr. Röder related some

Cases of Late Death from Chloroform.

Five cases were reported of young people who had previously been healthy, and in which the operation for which the chloroform was given was uncomplicated—four cases of operation for appendicitis, and one for nephrectomy. They all died on the fourth day following the operation. They felt well in the early part of the day after the operation, but, later on, they lost consciousness. The pulse, temperature, and character of the urine were unchanged. This condition lasted until 75 to 90 hours after the operation, when they died. In all the cases the post-mortem examination revealed fatty degeneration of the heart and kidneys. As everything else (sepsis especially) could be excluded, nothing remained to account for the condition but the action of the chloroform. These baneful consequences could not be foreseen. The speaker counselled the use of ether in place of chloroform, or, wherever possible, lumbar anæsthesia.

Hr. Bruno Wolff related a case of

Tuberculous Ulcer of the Labium.

He said that tuberculous infection of the vulva was comparatively rare, and each case still possessed a special interest. The case related was one of tuberculous ulcer of the left labium minus. Even clinically there was a suspicion of the tuberculous nature of the ulcer. It was excised, and the suspicion was confirmed by microscopical examination. Before this, the patient had had tubercle of the sheaths of the tendons of the right hand; she had also suffered from phthisis pulmonum. The speaker believed that the infection had reached the labium by the hæmogenous route. From a study of the literature of the subject he had determined that there was only the very slightest tendency of the disease, ascending to the higher parts of the genital track. In the case under notice, although it had been present six months, it had not ascended beyond the introitus vaginæ. The case supported Baumgarten's teaching, which was to the effect that tuberculosis of the female genital organs spread "as good as exclusively" in a downward direction.

AUSTRIA.

Vienna, April 14th, 1907.

Intestinaal Invagination

At the Gesellschaft, Flesch showed preparation from a child that died from the accident unrecognised during life. The whole symptoms pointed to a perforation at the appendix and the swelling diagnosed as an abscess proved on the post-mortem table to be an invagination of the bowel.

Infantile Tetany.

Escherich exhibited a child with abnormal sensitiveness to all stimuli, mechanical and electrical. For two months the child had suffered from general disturbance in the alimentary canal, vomiting, loss of appetite, and emaciation. From time to time typical croup was present, stridant inspiration with cyanosis. If the finger were drawn across the cheek the facial phenomena of spasm and paralysis would be induced. The same contractions would occur by tapping with the fingers or applying a feeble electric current to any part of the body.

Finkelstein has affirmed that if a milk diet be avoided in these cases they will immediately recover, which has not been the fortunate result in this case; on the contrary, the child was worse as soon as the milk diet was withdrawn. This is not to be wondered at, as a large number of children fed on farinaceous products have become afflicted with tetany as well as those fed on milk.

To determine whether this facial phenomenon was due to the mechanical stimulus or some morbid change in the reflex function, the face was painted with a 10 per cent. solution of cocain to anæsthetise the part, and apply a feeble current to the body; in spite of this precaution the facial phenomenon was as great as ever.

Spieler confirmed the worthlessness of the milk abstinence treatment as a barren illusion, and cast doubts on many of the authors who had obtained miraculous results from the use of phosphated cod liver oil. He always found the earliest symptom to be anod opening contraction to be greater than the anod closing contraction.

Pirquet thought the difference between the anod opening and anod closing was not so much to be relied on as the absolute amount of the anod opening below 5 milliamperes. The question arose whether the anod closing was before or after the anod opening.

Spieler replied that his experience was that the anod opening was always first, no matter how small the amount.

Neurath thought the question to decide was, what relation existed between the increased motor power and electric stimuli in these tetenoid, or spasmophile children. He had made a rough examination of a large number of children, and found 60 per cent. to 70 per cent. had this facial phenomenon produced by the current. He attributed this phenomenon to a respiratory defect, probably a respiratory poisoning. Pirquet objected to this assertion, as he had examined 500 healthy children and found the facial phenomenon present in 3.8 per cent. only.

Tick Fever.

Fraenkel showed a microscopic preparation with the spirillum of tick fever, produced in the human subject by the bite of the Ornithodorus monbatus or the Argus miniatus. The spirillum could be seen moving round the corpuscle and sometimes disappearing. The infection can be easily transferred to mice, rats, and monkeys, the latter taking ill on the second day after inoculation, and the spirillum appearing three or four times in the twenty-four hours.

Infection by Lymphatics.

Weleminsky has been experimenting with injections and contacts in the hope of discovering the path of entrance. He assures us that the infectious germ passes from gland to gland, when applied to different parts of the body and to the bronchial glands, where it enters the blood circulation and produces general infection. The whole lymphathic system is capable of taking up the poison.

It is said that the petition to the council of the Royal College of Surgeons, asking that women should be admitted to the examinations, has been signed by about 3,000 members.

CONTINENTAL HEALTH RESORTS

KREUZNACH.

Bad-Kreuznach, of far-spread and well-merited renown, and easily accessible by Flushing, Hook of Holland, and other routes, is picturesquely situated in the Nahe Valley; and in the world-wide famous neighbourhood of Bingen-on-the-Rhine, the most charming section of the Rhinelands. Its altitude above sea level is 105 metres, and it enjoys a tonic and delightful atmosphere, with a bracing air, coming over well wooded hills, from the Hunsruck Mountains, and largely impregnated with ozone from these forests, and especially from the neighbouring salt works, where the celebrated Kreuznach-salts and Mother-lye are crystalized from dripping brine-water in the Gradirhauser evaporating sheds. These ten Saline Springs are now owned by the Kreuznach Municipality, and under admirable management. There are also Thermal Springs in Kreuznach itself, of which the strongest mineralized one belongs exclusively to the popular Oranienhof Hotel, formerly the summer palace of Princess Mary of Orange. Another famous Spring is the Elizabeth-brunnen, the waters of which are drunk on an island in the extensive Kur-Park, amidst grand old forest trees. In the Kur-Gardens excellent bands play three times daily, during the summer season; the Symphony Concerts of Kreuznach ranking amongst the finest musical entertainments of Germany. During this season are also theatrical performances, balls, races, floral contests, fireworks, children's gymkana, &c. The vicinity affords a variety of excursions, hunting and fishing. So that a sojourn at Kreuznach is in many ways very enjoyable.

The Mineral Waters of Kreuznach, containing bromides, iodides, lithium, chlorides, barium, magnesium, and radium, have for many years proved highly beneficial in treatments for gout, rheumatism, obesity, tabes, chronic catarrh, heart, eye and ear affections, feminine complaints, skin troubles, cancerous growths, fibroid tumours, rickets, bone and joint diseases.

The Saline waters are conducted from the Springs to several baths and hotels. Attached to the Kurhaus is a spacious *Inhalatorium*, having ingenious apparatus for evenly diffusing the air. Carbonic acid, electro-light, mud immersions, and other approved therapeutic appliances are also used. The vapour baths here differ from the ordinary Russian and Turkish baths elsewhere, in that the hot air passing through mineral waters becomes charged with their free carbonic acid gas and other medicinal qualities The Terrain, Kefyri, Whey and the Grape "cures" are likewise in vogue at Kreuznach.

Sanitation has careful attention; and what is not so usual as might be desired at many Continental Resorts, Kreuznach gives its visitors an abundant supply of the purest drinking water.

Patients suffering from Debility after severe illness (especially after malignant Influenza), and also those suffering from Anæmia or susceptible to Apoplexy and other diseases connected with the central Nervous system, are considerably helped by a course of the Waters at Kreuznach, where they find everything conducive to convalescence and restoration to health.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Edinburgh Medical Lecturers and the Dublin University.—The following memorial, signed by all but one of the lecturers of the School of Medicine of the Royal Colleges, has been forwarded to the Chief Secretary for Ireland:—"We, lecturers in the School of Medicine of the Royal Colleges, Edinburgh, most respectfully submit that we profoundly regret the proposed legislation in connection with the University of Dublin. As teachers in a great medical school, and living in an influential centre of education, we regard the proposed compulsory incorporation of widely separated colleges under a single university as fatal to the best interests of any teaching scheme. The historic associations of Trinity College, the great men it has given to the world, its present high and liberal standard of education, command the deepest respect throughout the British Empire. We should deplore, as a national calamity, any legislation which would cancel the charter of the University of Dublin, as it would inevitably diminish the prestige which justly surrounds the degrees conferred by that University."

EDINBURGH UNIVERSITY GRADUATION CEREMONIAL.—More than ordinary interest was manifested in the spring graduation ceremonial, which took place on April 12th, on account of the presence among those on whom honorary degrees was conferred of several of the colonial Premiers—the Hon. Sir Joseph George Ward, K.C.M.G., Prime Minister of New Zealand, the Hon. Frederick Robert Moor, Prime Minister of Natal, and the Hon. Leander Starr Jameson, M.D., C.B., Prime Minister of Cape Colony. Of the last, Sir Luddon Grant said:—"As a pioneer of empire, the British South Africa Company may challenge comparison with the most famous chartered companies of yore, and this is due mainly to the genius and force of two striking personalities. The one is the late Mr. Cecil Rhodes, and the other the illustrious native of Edinburgh, who now stands in our midst. Before he turned his hand to the great work with which his name is now specially identified, Dr. Jameson, I should remind you, had risen to the summit of the medical profession in South Africa, and it is interesting to recall that amongst other distinguished patients who benefited by his skill and advice was the late President Kruger. In the late war Dr. Jameson rendered distinguished services, and though scarcely seven years have elapsed since his entry into the public life of Cape Colony, his brilliant gifts and dauntless energy have carried him again to the foremost position." Among other recipients of the degree of LL.D. were two members of the medical profession—Professor D. J. Hamilton, Aberdeen, and Sir John Tweedy, late President of the Royal College of Surgeons of England. At the conclusion of the graduation ceremony a distinguished company was entertained to luncheon in the University Union, and in replying to the toast of his health, Dr. Jameson said that judging from what he knew of the opinion of the ministers of the other South African colonies, many years would not elapse before they had one Prime Minister to respond for the whole of South Africa. He praised the University Union as a club in which students from all parts of the Empire were mingling, and said that when Mr. Rhodes conceived the idea of establishing scholarships, his hope was that the Rhodes' scholars should be missionaries of empire when they got back to their own lands, having absorbed the culture which they got in this part of the empire. That great idea really came to Mr. Rhodes from the experience of the young men from South Africa who went to Edinburgh University.

ABERDEEN GRADUATION CEREMONIAL.—On the 9th of April the University of Aberdeen held its Spring graduation ceremony, and conferred the degree of LL.D. on Dr. T. S. Clouston, Dr. Campbell Brown, University College, Liverpool; Mr. W. S. Bruce, the meterologist and explorer, Professor Hale, Chicago, and others. Dr. Clouston's name, said the promoter, was known beyond the limits of the medical profession of our country and of our language. No man had more successfully ministered to minds diseased. He had educated the profession and the public mind into juster and truer conceptions of the causes of mental disorder, of responsibility, and of their remedies, by his many writings. As a witness he inspired a confidence not always associated with the evidence of experts. It was not the least of his praise that he had set out lawyers and judges free from some errors and prejudices which rested partly on ignorance, partly on a too rigid metaphysic. As a philanthropist and reformer of the law he more than deserved the degree.

EDINBURGH INFIRMARY AND LORD LISTER.—The managers have sent to Lord Lister a memorial conveying their respectful and cordial congratulations on his attainment of his eightieth birthday. They recall with gratitude his valuable and efficient services as a member of the surgical staff, and can never forget that it was while holding the chair of clinical surgery that he carried on that famous work which has formed an epoch in the history of medicine, has revolutionized surgery, and conferred untold benefits on mankind. The managers desire to assure his Lordship of their continued interest in, and regard for him, and their earnest hope that every blessing may attend him in the time to come.

BELFAST.

THE HEALTH COMMISSION.—The sittings of the Belfast Health Commission during the past week have been chiefly devoted to the hearing of medical evidence. Four gentlemen, all ex-presidents of the Ulster Medical Society, spoke on behalf of the Society and the medical profession generally. They were Sir John Byers, Professor Lindsay, Dr. Calwell, and Dr. Dempsey. Sir John Byers occupied most of two days, and entered fully into all the health problems of the city. After dealing with the general death rate he took up that from typhoid, and infant mortality, showing how these were far too high in Belfast. He was inclined to blame the water supply for our constant typhoid, and advocated the placing of the water supply under the control of the Corporation, instead of its being under a separate board, as at present. The frequent flooding of certain parts of the city and the pollution of the Lough by sewage having been disposed of, the witness entered very fully into the question of the milk supply, with which he is specially competent to deal, as he has devoted much attention to it for years past. Briefly he advocated a very full inspection and control by the Corporation as the only way of safeguarding the people, and especially the children, from one of the most frequent sources of infection. The position of the dispensary officers, who are the medical officers of health in their districts, Sir John Byers did not consider satisfactory—that is, as regards their relation to the municipal authorities. There is at present a very defective system for transmitting to the latter particulars of the cause of deaths. On the second day Sir John Byers dealt with the effect of emigration on the death rate in Ireland generally, and then on Belfast in particular. He showed that large numbers of young people come into the city from the country, and ought to lower the death rate of the city rather than otherwise. Consumption and its relation to the textile manufactures of Belfast then came under notice. While flax spinning undoubtedly contributes to the prevalence of tubercular disease, the witness was inclined to attribute more blame to the insanitary houses of the working classes and the general want of cleanliness in them. With some remarks on the provision for the treatment of consumptives, and on the sanitary state of the schools of the city, the witness concluded his lengthy and important evidence, and was thanked by the chairman of the Commission, Colonel Harding. Professor Lindsay took up first the want of particulars of many important matters in the annual health reports of the city—a matter which has been commented on year after year for some years past in this column. No particulars are given regarding overcrowding, dairy prosecutions, flooding, the working of the main drainage, the pollution of the Lough, and many other important matters. He then entered fully into the question of phthisis, of which, he said, the main causes were undoubtedly overcrowding, bad air, and bad ventilation. The accommodation for the treatment of these cases was most insufficient, and isolation was most essential for the safety of the people. Dealing with the influence of the flax trade on tuberculosis, Professor Lindsay said that he would draw the conclusion that while the staple trade contributes to our phthisis rate, it does so probably only to a moderate extent. Dirt he believed to be an enormous factor, and one of the things needed in Ireland was a propaganda of cleanliness. Regarding the treatment of the disease, he said that an ideal method would be a threefold one—a sanatorium for incipient cases, a tubercular colony to deal with cases that were fairly advanced, and an institution for incurable cases. In the colony the patients would do some light work, such as gardening. Typhoid was then considered, and the causes were given by the witness as impure water, pollution of the soil, and dissemination of fæcal matter by careless persons. The theory of its spread by dust he thought was disproved. As regards Belfast he believed there were permanent causes at work in the state of the soil and the character of the houses, and these were reinforced by the pollution of the water supply, causing epidemics. After dealing with the inspection of schools, Professor Lindsay summed up with several recommendations, the first of which was that Dr. Bailie, the lately appointed Medical Officer of Health, should get a thoroughly trained assistant, a man who had devoted his life to public health work in some other large city. This, of course, is the type of man the medical profession urged the Corporation to appoint when the post was vacant last year. Their opinion was ignored, and Dr. Bailie, a general practitioner, lately a member of the Corporation, appointed, hence this Health Commission. The other points were clearing of insanitary areas, increased hospital accommodation, and especially further hospital and dispensary provision for phthisis. Dr. Michael Aitken gave evidence as to the sanitary condition of the working class houses in the city, as observed by him in a general practice. Dr. Dempsey, who has been in practice in Belfast for thirty-three years, and is senior physician to the Mater Hospital, said that he agreed generally with the evidence of Sir John Byers and Professor Lindsay, so would not go over the same ground. He spoke specially of the necessity for more open spaces, and of the objectionable matter often used to fill in low land for building purposes. The drain-testing he also regarded as most unsatisfactory. He urged the teaching of hygiene in schools, saying it would be more useful than French or German. When asked if he would prefer it to the teaching of Irish, he declined to commit himself. Dr. Calwell began his evidence with a quantity of statistics to prove the many and glaring deficiencies of the Belfast health reports, supplementing Professor Lindsay's evidence on this point. He then dealt with the questions of typhoid and consumption, and gave figures to compare Belfast with other cities. He agreed with Professor Lindsay as to the treatment, and said he had great hopes of the result of teaching cleanliness in the schools. He had no doubt as to the danger of typhoid infection from the Belfast water supply, but he also attributed some cases to milk and some to shellfish infection.

Cerebro-Spinal Fever.—The number of cases of this disease notified during the past week was 22, a slight falling off from the week before. The total number now reaches 263, with 177 deaths. There have been several deaths of adults, including one of a nurse who had taken a patient from his home to the fever hospital, and a police constable, who died after a few hours illness.

LETTERS TO THE EDITOR.

THE QUACK MEDICINE TRADE.

To the Editor of The Medical Press and Circular.

Sir,—The following paragraph appears in *The Times* of April 8th:—"Mr. Thomas Beecham, the founder of the well-known pill business at St. Helens, Lancashire, died at his residence at Southport, on Saturday. A native of Oxfordshire, Mr. Beecham went first to Wigan and afterwards to St. Helens where he remained for 40 years. At both place he sold pills at a stall in the market-place. Later it is estimated that the firm spent £120,000 a year in advertising. Mr. Beecham retired from business 13 years ago, and went to Southport, where he built Wychwood. He took no part in public life." This notice is printed in the largest type, and occupies the most prominent position in the leader page. The significance of this needs very little comment for the medical reader. No doubt papers which have been receiving a share of the £120,000 a year will publish complimentary obituary articles, and will explain why the distinguished deceased gentleman "took no part in public life," for which his talents, as *The Times* seems to suggest, so well fitted him. Is it not time that the medical profession took steps to expose the character of the claims to public honour which seem thus to be put forth for the proprietors of quack medicines. Does not this notice in the leading journal make it evident that it will be impossible to bring about the desired exposure save through th medium of a Royal Commission—the method which you are now persistently advocating?

I am, Sir, yours truly,

Henry Sewill.

April 8th, 1907.

THE MILK SUPPLY—MILK AND TUBERCULOSIS.

To the Editor of The Medical Press and Circular.

Sir,—As I anticipated, the writer of the article to which I called attention in my letter of the 6th inst., is unable to refer me to a solitary instance in support of his belief in the communicability of tuberculosis by means of milk. I protest against the doctrine on the following grounds:—The late Sir Richard Thorne-Thorne told us, in his Harben Lectures on "Consumption," that while tuberculosis in the adult had diminished 50 per cent. in the last quarter of a century, it still claimed a large, but also diminished, number of victims amongst children, and he attributed the latter to the fact that children are fed so much on milk.

I have very carefully looked into this question, and have already given the result in my paper on Bacteriology. But it seems to have been overlooked, and will therefore bear repetition.

In 1892 Mr. R. Henry Rew instituted an enquiry into the statistics of milk consumption in various districts. He presents the results in tabular form, which I now abbreviate in order to save space, omitting decimals. The table is drawn up on the basis of five persons in each family, and was published in the *Journal of the Royal Statistical Society*, April 26, 1892.

	gallons per annum.
West End of London (per family of 5) ..	34
North of London	29
Manchester	24
,, Middle-class District	13
,, Working-class	9
East End of London	3

"With reference to the last," he says, "it is necessary to explain that the figures are based on the fact that a gallon of milk is divided, on an average, into *thirty-seven* portions. . . . I have assumed that such family consumes one of these portions every morning and evening. It will be seen that even on this assumption, the consumption per head is infinitesimal, and it reveals, incidentally, a significant fact in connection with the dietary of the poor."

It is a fair assumption that what applies to the East End of London, applies also to all the poorer districts of London what are commonly called the "Slums."

Now I assume that no one will contest the statement that *Tabes Mesenterica*—the disease in question—occurs chiefly, if not wholly, amongst the children of the poor and indigent. At least I have never seen a case amongst those of the well-to-do. The disease is essentially one of real nutrition, and is curable by nutritious diet, of which milk, not sterilised, should form an essential part.

Why does this form of tuberculosis attack the digestive tract rather than the pulmonary? Because, said the lecturer, the tubercle bacillus gains entrance through the stomach. I venture to affirm that not a solitary case has ever been put on record in which this disease has been thus communicated. Rather, it is the *want* of milk.

I am not prepared to contest the statement of the writer of the article, in his reply, that "it is now scientifically proved that 'live' tubercle bacilli can be conveyed in milk." It is probably correct. But I cannot accept the deduction that "if milk thus infected be swallowed by children, there is a reasonable certainty that, by the law of averages, cases of tuberculosis *must* result." It is this habit of assumption that I complain of, and must resist.

In the paper referred to I have put on record a very striking case of a large tuberculous tumour of the omentum, with deposit of tubercle in the parietes, absolutely cured by abdominal section, and the subject is now the "picture" of good health. The subject, æt. 16, was the daughter of a farmer, and a thorough-going believer in the microbic theory would, no doubt, at once point to this case in support, or even proof, of his contention. But the singular fact remains that this young lady was the only one (of a healthy family) who could not be prevailed upon to take milk, *or* cream, in any form.

I am well aware "of the extreme difficulty that attends the positive identification of the agency of the conveyance of specific zymotic infection not only in 'many' but in all 'cases.'" It is because of this difficulty that I plead for less persistence in cramming this doctrine (to use homely language) "down our throats."—I am, Sir, yours truly,

GEORGE GRANVILLE BANTOCK.

14, Upper Hamilton Terrace, London, April 12th, 1907.

OBITUARY.

FERDINAND A. PURCELL, M.D., M.R.C.S.

WE regret to have to record the death of Dr. Ferdinand A. Purcell, who died at his residence, 7, Manchester Square, London, W., in his seventieth year. He was for many years Surgeon to the Cancer Hospital, Brompton, and was the first surgeon in Great Britain for perform vaginal hysterectomy for cancer of the uterus. He was a member of the Council of the Medical Defence Union, and a regular attendant at the meetings, taking a lively interest in the welfare of the Society. He was, moreover, a Foundation Fellow of the British Gynæcological Society, and contributed several papers of interest and importance at their meetings. Dr. Purcell was author of "Cancer, Its Allies and Other Tumours," and contributed several papers on cancer and allied subjects to THE MEDICAL PRESS AND CIRCULAR, and other medical periodicals.

WILLIAM SNEDDEN, M.D., L.R.C.S.

DR. SNEDDEN's death took place with tragic suddenness on the afternoon of April 11th. He had been in apparent health, and had only complained of being slightly out of sorts on the morning of his death. He participated in the spring competition of the Glasgow Medical Golf Club in the forenoon, and after lunch played a few holes against Dr. Edwards, Glasgow, when, as he reached the third green he dropped and immediately expired. Dr. Snedden was a Glasgow graduate, and had practised in Beith for over thirty years. He was a J.P. for the county, and a surgeon-colonel in the volunteers. A first-rate shot, he represented Beith Company in many of its matches. Among other appointments he was medical officer to the local authority, and had a large practice. He was greatly esteemed in the neighbourhood, and his loss is much regretted. He was a widower, and leaves two sons and two daughters.

EDWARD T. D. HARRISON, F.R.C.S., L.S.A.

WE regret to announce the death of Dr. E. T. D. Harrison, F.R.C.S., of Clifton, formerly of Welshpool. Dr. Harrison, who died in his 88th year, was descended from one of the oldest families in Montgomeryshire. He qualified as a Member of the Royal College of Surgeons as long ago as 1842, and proceeded to the Fellowship in 1883. For many years he was in busy practice at Welshpool, and he was an enthusiastic volunteer. Dr. Harrison, who retired from practice about a quarter of a century ago, and then removed to Clifton, was one of the members of the original Commission of the Peace for Welshpool, and on four occasions was mayor of the borough.

H. HOWELL PARRY, M.R.C.S.

WE regret to announce that Dr. H. H. Parry, of Bontnewydd, near Carnarvon, died with alarming suddenness on April 4th. He returned from Carnarvon in the course of the afternoon in his usual health, and a short time later a lad in his employ found Dr. Parry prostrate on the ground and wholly unconscious. Medical aid was summoned from Penygroes and Carnarvon, and examination showed that he had had a paralytic stroke. The illness proved fatal, and the sad event caused a profound sensation in the neighbourhood, where the deceased had resided for a considerable period. He was one of the oldest medical practitioners in that part of North Wales, and extremely popular among his neighbours. He had studied medicine at Queen's College, Birmingham, and qualified, M.R.C.S., in 1862. Settling at Bontnewydd, he became surgeon to the Alexandra and other slate quarries in the neighbourhood, and gained large experience in accident cases.

SPECIAL ARTICLE

PLAGUE IN NEW SOUTH WALES.

THE Board of Health of New South Wales has issued as a Government publication (*a*), a full account of the outbreaks of plague in the State in the year 1905. The various outbreaks at Sydney, at Newcastle, and on the Clarence and Richmond Rivers are dealt with respectively by Dr. Ashburton Thompson, Dr. Robert Dick, and Dr. R. J. Millard. Careful attention is given in each case to the relation of plague in man to plague in rats, and to the various epidemiological conditions which governed the outbreaks.

The most valuable part of the volume, however, is the appendix containing Dr. Ashburton Thompson's views on the epidemiology of plague, as presented in an address to the Congress of the American Medical Association held in Boston last summer. He points out that the opportunities of studying the subject have been greater in New South Wales than elsewhere, since nowhere else in modern times has there been an epidemic of plague in a community of civilised and intelligent white men.

His main conclusions he states in four propositions:—(*a*) Plague owes nothing of its epidemic form to communication with the sick; (*b*) Plague in the rat is a necessary factor in epidemic plague; (*c*) A living intermediary is necessary to communicate the infection from rat to man; (*d*) That intermediary must be the flea in one or more of its many species.

With regard to the varieties of rodent which may act as carriers of plague, Dr. Thompson found plague not only in the grey rat, but also in the black rat, the Alexandrian rat, and the grey mouse. The number of plague rats found on infected premises was usually small, from three or four to half a dozen, but in a few cases very large numbers were discovered, *e.g.*, from fifty to one hundred and eighty.

Dr. Thompson argues strongly in favour of the view that fleas are a necessary intermediary between the rat and man in the transmission of plague. Having combatted the idea that plague can be inoculated by accidental contact between an infected object and an abrasion of the skin, he goes on:—"The result of continuous examination of our rats has

---

(*a*) "**Report of the Board of Health on Plague in New South Wales, 1905.**" **Sydney: W. A. Gullick. 1906. 67710. 8s.**

been to show us that rat plague always coincides in place with plague in man, and in time always precedes it; but the presence of plague rats was not always attended by plague in man. If, however, infection of the rat be a necessary condition of epidemic plague, a closer connection between plague rat and man should be traceable. Accordingly, house association between the two was often discovered. But often, on the one hand, it could not be discovered; and, on the other, often when it was discovered it was not attended by cases in man. Further, the commonly accepted observation that actual contact with the plague rat is unnecessary to infection of man was corroborated, and as a matter of observation was learned to have occurred very rarely. Moreover, such contact when it had occurred, was generally not followed by infection; and that, it will be observed, was in accord with a very extensive laboratory experience which shows that the many persons who now habitually dissect plague rats invariably escape infection, provided they do not wound themselves with their scissors and needles. The contradictory character of these several observations stands forth. The unavoidable inference from them is that if epizoötic plague is a condition precedent of epidemic plague, yet the plague rat cannot be the only factor concerned."

As regards seasonal incidence, plague has been found to be most prevalent in both man and the rat, in the autumn. This is also the season of fleas.

"It is well known that different species of fleas have their proper hosts, and prefer them to other kinds of animals. Human fleas do not *infest* rats, and rat fleas do not *infest* man; were it otherwise the rule, perhaps, would be to find multiple cases in plague-houses instead, as is the case, of finding only one person infected out of several equally exposed to the danger. Why, then, should it be supposed that rat fleas will leave the rat for man? In 1905 Liston made the suggestion that they remain with their proper host as long as it is available, and when it dies, or is withdrawn, proceeds to seek food from the next nearest animal. Rats having died of plague in a public garden at Bombay near a cage of guinea pigs, presently the latter began to die of plague; and on searching the survivors he was able to collect from them a good many specimens of *P. pallidus* (P. *Cheopis*, Roths.), which in Bombay and in Australia is the common rat flea, although guinea pigs in India (and in Australia) seldom possess any fleas at all, and when they do so harbour only one or two specimens of *Ct. serraticeps*. He observed also transfer of the common rat flea from rat to man. His attention was drawn to people who had been expelled from their house by the attacks of fleas. It appeared that on the 6th or 7th of a month the rats in the house had begun to die of plague; on the 11th fleas became so troublesome that the people had to sleep out on the verandah; on the 17th one of them fell ill with plague, and after him another. On the 20th Liston collected thirty fleas on the bodies of the remaining persons. As many as fourteen of them were of the species of *P. pallidus*; yet among 246 fleas collected by him from the clothes of various persons under ordinary conditions, but a single specimen of *P. pallidus* was found. May this indicate the reason of our observation that man takes plague only after rats have died of it?"

The Report deserves the careful attention of everyone interested in epidemiology.

BY order of Princess Christian, the president, a special general meeting of the Royal British Nurses' Association was summoned "to consider recommendations with reference to the grant of a diploma in nursing by the corporation." The meeting was held on Friday, April 12th, in the rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, W.

REVIEWS OF BOOKS.

MARSHALL ON SYPHILOLOGY AND VENEREAL DISEASE. (*a*)

WHAT have English surgeons been doing for the last twenty-five years with regard to venereal diseases? Evidently nothing; for, according to Dr. Marshall, "during that period no book has been published in England dealing in a systematic manner with syphilis and venereal diseases." Therefore he steps boldly into the breach to make up by his present work for the shortcomings of his countrymen, and so well does he do this that we cannot help feeling that we should be more interested in the book if it contained a little more of Marshall and a little less of other people. Most writers on venereal diseases (even twenty-five years ago) commence with historical notices in reference to the antiquity of syphilis. Dr. Marshall follows this lead, and gives his reader a capital peep into this nebulous subject. His second chapter, "Generalities," gives us nothing new; surely, however, alcohol cannot be the "born enemy of syphilis," but rather the "born friend," as it encourages the disease in every way. Dr. Marshall contradicts himself when he says: "Syphilis is in most cases contracted from a *sore* in the genitals . . . by kissing people with syphilitic *sores* in the mouth," as on the preceding page he rightly asserts, "the mucous patch is probably the lesion which is responsible for most syphilitic contamination." We heartily agree with Dr. Marshall when he says: "The prognosis [of syphilis] . . . depends chiefly on the duration of treatment." The chapter on the pathology of the disease is interesting, especially the few words on parasyphilis and the experimental researches for the spirochæta pallida. The next two chapters, "Chancres" and "Syphilides," add nothing to what is already known on these subjects. Many will be found to doubt the dictum in Chapter VIII. that "Syphilis is a powerful predisposing cause to tuberculosis." Sixty-five pages are taken up with two exhaustive chapters, one on syphilis of the nervous system and the other on parasyphilis or quaternary syphilis of the nervous system; both of these well repay perusal. In dealing with the general treatment of syphilis we are glad to see the author gives his own scheme of treatment, which certainly is an excellent one, though it necessitates having the patient under observation for seven years. Hereditary and congenital syphilis, in Chapter XVI., systematology of Heredo-syphilis and syphilis of the third generation, in the following chapters are all set forth in a concise and readable style. Two short chapters only at the end of the book are devoted to gonorrhœa and simple chancres. Undoubtedly a most useful work; for if Dr. Marshall has not given his readers as much of his own experience as they might desire, he has undoubtedly furnished them with a magnificent compilation of the opinions of (mostly foreign) experts, most useful for reference. The book, too, is in a very handy and suitable form, as its size is very convenient and the printing is irreproachable.

THE CHEMICAL INVESTIGATION OF GASTRIC AND INTESTINAL DISEASES (*b*).

"THE practice of medicine is becoming what it was long ago, but injustly called a true science and art." (*c*) The preface to Harley and Goodbody's book opens with a somewhat similar remark. In both statements the allegation is made that the practice of medicine in its entirety is not scientific, nor can it be said that

Goodbody, M.D., etc., Assistant Professor of Pathological Chemistry, University College, London. Pp. viii., and 261. London: Edward Arnold. 8s. 6d. net.

(*c*) Simon: Clinical Diagnosis.

the accusation is without foundation. Treatment must of necessity be tentative and empirical where the cause of the disease is unknown or but imperfectly understood. It is unfair, however, to lay all the blame for lack of science in treatment at the door of the clinician. He can only be justly found fault with when he fails to take advantage of the resources which scientific investigation placed at his command.

It is the immediate province of pathology to discover causes, and of both therapeutics and pathology to find out remedies. To do either requires an accurate appreciation of the factors upon which the normal functional activity of the diseased organs depends. Thus the physiologist has also to share in the responsibility for the carrying out of rational treatment.

Nowhere in the whole range of therapeutics is an accurate knowledge of function more necessary for scientific treatment than in diseases of the alimentary canal. Consequently the question is here a very pertinent one: Have we accurate knowledge of the digestive processes in the alimentary canal in health?

Physiologists do not claim that everything concerning the functions of the organs of digestion is within their ken, but nowhere has more rapid progress been made of late years than in this field. Witness the all-important results of the investigations initiated by Ivan Petrovitch Pavlov, and carried on for the past fifteen years under his guidance in the St. Petersburgh Institute for Experimental Medicine. These are of the greatest moment in themselves, but they are not less valuable on account of the stimulus they have given to workers in other lands to labour in the same field. Of these latter none have accomplished more fruitful achievements than some in our own country, notably Starling and his fellow workers, colleagues of the authors of the book under review.

But it takes time, often long periods of time, for knowledge acquired in the laboratory to become reflected in the practise of clinical medicine and surgery. This is in part due to a certain degree of conservatism in applying the results obtained on animals to the human subject. But it is to be feared that its chief cause is a lack of sufficient inter-communication between the representatives of subjects closely inter-dependent upon one another. To take the extremes in the series just mentioned the physician is too little of the physiologist, the physiologist too little of the physician. It is the exception rather than the rule to find physicians in this country with sufficient knowledge of technique to carry out adequate laboratory investigations, particularly of a chemical nature, which would aid them in the diagnosis and treatment of disease. In consequence few of the older men particularly are fully able to appreciate or profit by the additional knowledge acquired in this way.

It is quite true that physicians as a rule have not sufficient time to carry out investigations of this nature themselves, but it is equally true that they should be carried out, and this entails upon the physician the duty of having laboratory facilities and assistance for the purpose. There can be little doubt that this will ultimately come to be generally recognised. To Dr. Vaughan Harley in this country is undoubtedly due the merit of having introduced the systematic employment of extending laboratory investigation in the diagnosis and treatment of diseases of the alimentary tract. His wide training in the methods of chemical physiology and pathology, as taught in continental schools, has been turned to daily use in the practise of his profession. A laboratory and assistance are indispensible. But Dr. Harley has been fortunate in finding amongst the pupils he trained, an assistant, now a colleague, no less enthusiastic than himself, namely, Dr. Goodbody, joint editor of the book.

The first seven chapters are devoted to descriptions of methods employed in the chemical investigation of gastric and intestinal diseases. The chapters have the merit of being short, and the methods are succinctly described. Useful practical hints are given on such points as the passage of the stomach tube, the choice of test meals, the general examination of the gastric contents after withdrawal, &c.

In dealing with qualitative chemical examination of the contents, the usual methods are described, methods which unfortunately in the vast majority of cases, constitute the beginning and the end of the investigation. By such limitation it is impossible to differentiate many of the more obscure disorders of the stomach. It is, for example, as the authors say, insufficient to determine, that an individual suffers from "acid dyspepsia," the degree and form which it assumes are of the essence of the diagnosis, and cannot be ascertained without quantitative analyses.

Following the chapters on methods, three are given to organic diseases of the stomach in which catarrh of various kinds, gastric ulcer and gastric carcinoma are treated of. In the discussion of each of these, valuable practical hints are interspersed, and in every case tables of analyses are added. These latter cannot fail to be of use for comparative purposes in future investigations. In the diagnosis of gastric carcinoma the authors place chief reliance not on the total absence of HCl, but on the absence of *free* HCl, as well as on the early and pronounced increase of lactic acid.

Functional diseases of the stomach are dealt with under disorders of secretion of motility and of sensibility. The three chapters devoted to these are amongst the most useful in the book.

It is, however, open to question whether any such condition as hyperchlorhydria exists. Hyperacidity is, of course, a common occurrence, and the table of cases of hyperchlorhydria includes striking instances of this condition, but in no case does the amount of hydrochloric acid rise above 0.48 per cent., and in only 3 is it above 0.4 per cent. These figures are well within the normal range according to recent investigations.

Relative to sensory neuroses a shrewd observation is made concerning the excessive degree of pain often produced by small quantities of bubyric and other volatile acids. It might be added that the seat of origin of the pain is nearly always the pyloric mucous membrane, and that it is generally associated with pyloric spasm.

The second part of the work treats of intestinal diseases. It is no reproach to the authors to say that it furnishes less satisfactory reading than the first. This is due to the fact that although in recent years considerable advance has been made in the chemical diagnosis and treatment of intestinal diseases, the field is comparatively unexplored. It is, however, one of paramount importance and can hardly fail to repay systematic investigation along scientific lines. There seems little doubt that ideas now prevalent regarding the general and dietetic treatment of diseases of the intestinal tract are bound in the near future to undergo radical alteration. That many intestinal diseases fall into the hands of the surgeon, whose methods are coercive and in no sense strictly curative, is evidence that much remains to be done.

The remaining chapters deal in order with motor power of the intestines, intestinal "dyspepsia" or fermentation, intestinal catarrh, colitis, intestinal atrophy, ulceration, carcinoma, sprue and intestinal concretions. The authors are quite cognisant of the limitations of their present methods in seeking to differentiate some of the conditions enumerated here, and frankly state so. Nevertheless, interesting and new matter infrequently appears.

We may add that the book is attractively got up. The type is clear, a full index is added, and we consider the work unique of its kind amongst English text-books.

WAR WITH DISEASE. (*a*)

"War with Disease" is, we believe, the first attempt made by a medical man to throw into book

---

(*a*) "War With Disease." By Frederick F. Maccabe, M.B., Medical Officer, South of Ireland Imperial Yeomanry, late Civil Surgeon, H.M. Field Force, South Africa. Second Edition. London: Baillière Tindall and Cox. 1907. 1s. net.

form, for the benefit of the soldier, the elementary teachings of hygiene. This little work, therefore, does not call for too critical a handling, for the scope of the subject and the method of presentation naturally lend themselves at this stage rather to experiment than to exact treatment. So that while each man would have his own views as to the plan of such a book and the amount of information it should contain, it is not necessary to say more than that Dr. Maccabe has produced an interesting, readable, and suggestive short treatise which forms in itself an admirable basis for future endeavours of the same character. Indeed, we hope that having now attained to a second and improved edition, we shall find this book pass through many more, each better than the last. There is no reason why it should not, for not only does it contain much valuable information carefully collated and thrown into bright, simple language, but it has already gained so much favour at the hands of the authorities that many regiments are taking it as their handbook in the formation of sanitary classes and sections. Consisting as the book does of the substance of three different series of lectures delivered to military classes as widely different in intellect as the officers of the Staff College and the cavalry recruits in Ireland, there is necessarily much want of symmetry in arrangement and matter, but there is no reason why a little rearrangement and recasting should not produce a systematic and agreeable text-book, especially if the purely anatomical chapter were omitted. Dr. Maccabe throughout tackles his subject in a straightforward and workmanlike fashion, and giving just enough theory to make his directions comprehensible to the lay mind, devotes himself in laudable fashion to the practical questions of disease-prevention in the army, in camp and on service. While he is rightly dogmatic in his instruction, we do not find we can go all the way with him in several instances; for instance, we do not share his faith in the efficacy of permanganate of potassium as a preventive of gonorrhœa. But, as we have said, for a first attempt in breaking new and rather difficult ground, this book deserves warm commendation, and there would be fewer graves in South Africa at the present moment if its teachings had been known and practised during 1899-1902.

LITERARY NOTES.

That Professor Buchanan will have increased his reputation as an anatomist by the completion of his great work on the subject will be at once admitted by those qualified to pass judgment, now that the second volume is before them. His new "Manual of Anatomy, Systematic and Practical, including Embryology," in the University Series, reveals the author in the light of a great and practical teacher, who, having set before himself a task, the immensity of which can only be gauged on reference to the book, devotes, to use an idiomatic expression, "his heart and soul" to its accomplishment, giving us as the result of his labours one of the most original, complete, and best illustrated text-books on anatomy with which we are acquainted. We hope to review this work fully later on; meanwhile, we offer our congratulations to the author on the completion of his sterling work, and to the publishers on its attractive production.

⁂

The Jacksonian Prize for the year 1906, on "The Diagnosis and Treatment of those Diseases and Morbid Growths of the Vertebral Column, Spinal Cord and Canal which are Amenable to Surgical Operations," was awarded to Mr. Donald J. Armour, F.R.C.S., at the meeting of the Council of the Royal College of Surgeons, England, on Thursday last. The following subject was chosen for this prize for the year 1908: "The Pathology and Treatment of those Conditions and Diseases of the Colon which are Relievable by Operative Measures." The subject chosen for the next triennial prize was as follows: "The histological Anatomy of the Lymphatic and Hæmo-lymphatic Glands, more especially with reference to the changes which these glands undergo in acute infective processes."

⁂

Dr. Wm. Henry Drummond, the well-known Canadian poet, who died at Cobalt last week at the early age of 52, was born in Ireland and educated for the medical profession. He emigrated to Canada in early life, commenced practice in Montreal, eventually becoming Professor of Medical Jurisprudence at Bishop's University in that city. Literature, however, presented stronger claims on his tastes, and he devoted his undoubted talents to literary work and to poetry, chiefly illustrative of Canadian life in its various vicissitudes, the last of his poems being published only a few months since. He was a favourite author in the Dominion, although little known in Great Britain.

⁂

Messrs. Longmans, Green and Co. have just published a little volume entitled "The Care of Babies and Young Children" for the use of teachers, written by Miss Blanche Tucker, Inspectress of Elementary Schools under the Liverpool Education Committee. Its moderate price (1s.), and its useful information, will make it acceptable to the poor and ignorant if they can be induced to read it.

⁂

"French Law and Customs for the Anglo-Saxon," by Arthur S. Browne, the second edition of which is before us, is an uncommonly useful little book for British subjects who reside in France, either temporarily or permanently. Englishmen are, as a rule, profoundly, even contemptuously, ignorant of French laws and customs, with the inevitable result that they not infrequently find themselves in "tight corners" which a very little knowledge of local requisites would have spared them. The information here given will be found useful even by persons who only contemplate passing a season in France or its colonies.

⁂

The Editor of the *Business Man's Magazine* has sent us advance proofs of a most amusing article to appear in the present month's number. The title of the article is "The Polite Hospital Secretary's Letter Guide," and the writer presents a perfect picture of the hailstorm of letters that pours on the devoted head of a hospital secretary. The answers of that gentleman form an absolute type of the kind of ready writing in all matters that have to be argued by an official in that position. The cleverness of the article is exuberant, and will be found of interest by all interested in hospitals who possess a fund of original humour.

⁂

Last week's number of our contemporary, *The Graphic*, contains a very admirable portrait of Lord Lister, whose eightieth birthday was celebrated on Friday in all parts of the civilised world. We are indeed gratified to find the face of this illustrious surgeon in the pages of our lay contemporary, as its presence there is a tribute to the whole medical profession, which, in this particular instance, is glad to be untrammeled by ethical laws, and therefore not obliged to hide its light under a bushel. We find in the same number a beautiful reproduction of Daniel Maclise's painting of Charles Dickens. The association of these two eminent men in one issue of *The Graphic* is particularly happy.

The Hastings coroner held an inquest on April 5th on Dr. Thomas Vaux Woodifield, a retired medical man, residing at Vale-road, St. Leonards. The deceased, who was 70 years of age, had lived with a relative in St. Leonards for twelve years, being separated from his wife and family, who were legally represented at the inquest. Dr. Woodifield, who had fits of depression, was described as being very eccentric. He slept with a revolver under his pillow in the event of burglars, and ultimately shot himself with fatal effect. A verdict of "Suicide" was returned.

Weekly Summary of Medical Literature, English and Foreign.

Specially compiled for The Medical Press and Circular.

RECENT PATHOLOGICAL LITERATURE.

Gumma as a Cause of Stokes-Adams Disease.—Ashton, Norris, and Lavenson (*American Journal of the Medical Sciences*, January, 1907) publish with all details the history of a case of Stokes-Adams disease due to a gumma in the interventricular septum, causing destruction of the bundle of His. The authors were able to trace the bundle both above and below its involvement in the gumma, but at the latter there was a complete solution of its continuity. In the other parts of the course of the bundle there was considerable infiltration with small round cells and a growth of young connective tissue. The association of the Stokes-Adams syndrome with syphilis has been previously noted by several observers, including Handford, Keith, Miller, and Grünbaum, and in at least three previous cases, a gumma has been demonstrated in the course of the bundle of His. It is of practical importance that such cases may be amenable to iodide treatment, and Jacquet and Erlanger have reported a case of Stokes-Adams disease apparently cured by heroic doses of potassium iodide. R.

Auricular Fibrillation a Cause of Paroxysmal Irregularity of the Heart. — Cushing and Edmunds (*American Journal of the Medical Sciences*, January, 1907) relate a case of paroxysmal arrhythmia, and make suggestions as to the cause of the condition. The arrhythmia used to occur quite suddenly, and was accompanied with nausea and vomiting, while in the intervals of the attacks the heart beat regularly, and presented nothing abnormal. There was no reason to suppose that the ventricle failed to respond to the stimuli it received; the length of the apparent intermissions was not a multiple of the time of the single beats. During the periods of irregularity, the rate was greatly accelerated, sometimes rising to 150 a minute. The authors noticed a similar form of irregularity in the dog's heart during the performance of severe operations, and they were able to produce it experimentally by the administration of poisons of the digitalis series, or by the interruption of electrical stimulation of the vagus in the neck. In all these cases the auricle was found in the condition known as "auricular delirium," an extreme and continual incoordinated contraction, each part of the auricle undergoing fibrillary contractions independent of the rest. The authors suggest that the paroxysmal arrhythmia, both in their patient and in the animals subjected to experiment, was excited by auricular fibrillation due to inhibition of the vagus centre. R.

The Spread of Cancer.—Stevens (*British Medical Journal*, February 9th, 1907) publishes some observations on the mode of spread of cancer, particularly in the case of cancer of the stomach. He has noted that the clavicular lymphatic glands on the left side are frequently involved in cases of gastric cancer, whereas those on the right are rarely affected. The most obvious explanation of this difference is that the thoracic duct is a determining factor in the mode of spread. Stevens believes that the duct may either be a carrier of infective material or may itself be affected; several cases quoted support the latter alternative. Further observations of Stevens as to the mode of spread of cancer from the stomach to the other abdominal organs support the view that the growth proceeds by direct extension along the walls of the lymphatic channels. R.

Rumination in Man.—Brockbank (*British Medical Journal*, February 23rd, 1907) gives an interesting account of a family group in which rumination was common, and at the same time he summarises our knowledge of this peculiar condition. In all, he was able to study twenty-two individuals of the group, varying in age from two years to forty-seven, while he was able to obtain information of four other near relatives also subject to the habit. Eight of the subjects were brothers and sisters, while the other fourteen were among their immediate offspring. The habit in every case appeared to start at a very early age and was regarded by the subject of it as perfectly natural. Taking a typical case, food began to return to the mouth some quarter of an hour after a meal; it was chewed, and again swallowed. This process went on for one, two, three, or more hours, the food gradually becoming more fluid. There was nothing unpleasant in the process, except near the end, when the returned fluid had an unpleasant sour taste. Rumination was more marked after a meal of meat than after lighter food. In some of the subjects the habit was under control; in others quite independent of control. Brockbank's cases were apparently of the "simple" or "physiological" type, where the habit is quite natural; many recorded cases, however, are hysterical in nature, and among neurotics the habit may be learnt by imitation. In the majority of subjects of rumination, there is no anatomical peculiarity beyond some dilatation of the stomach and possibly of the lower end of the œsophagus. Brockbank adds some interesting information taken from the literature of this curious condition. R.

Aplastic Anæmia.—Lavenson (*American Journal of the Medical Sciences*, January, 1907), in publishing a case of this peculiar form of anæmia, collects ten other cases from the literature, and discusses the pathology at some length. He concludes: (1) Aplastic anæmia is a variety of progressive pernicious anæmia. (2) Its essential features are its rapidly fatal course; the marked diminution in the number of red corpuscles together with a low colour-index; absence of megaloblasts and usually of normoblasts; leukopenia with relative lymphocytosis; and, *post mortem*, pale bone-marrow without any sign of formation of red corpuscles. (3) The essential difference between aplastic anæmia and other forms of pernicious anæmia is the absence of regenerative processes in the former. Lavenson adds that the relation of lymphocytes to total leucocytes supports the view that lymphocytes are not a product of the bone-marrow. R.

Parathyroids and Accessory Thyroids. — Forsyth *British Medical Journal*, February 16th, 1907)] publishes the results of an examination of some sixty subjects as regards parathyroid and accessory thyroid glands. The number of parathyroids is usually stated to be two on each side, but Forsyth believes it to be very variable. In some cases he found only one parathyroid on one side, while in one case he found no less than six. Their position is also inconstant, and they are rarely symmetrical. The most frequent site is on the lateral surface of the thyroid gland, near its posterior border, at the junction of the lower and middle thirds of the gland. The parathyroid cannot be identified with certainty except by microscopical examination, but its most characteristic form is an elongated, slightly flattened, ovoid body, of a pale pink hue, with smooth surface, on which ramify a few branching vessels. In some specimens thyroid or thymus tissue was found along with parathyroid, but the latter was separated by a definite sheet of connective tissue. In size, the parathyroid varies from little more than a pin-point up to nearly 2.5 c.m. in diameter. The investigator found parathyroids in greatest number in the first year of life, and from that period to old age with progressively decreasing frequency. In subjects under twenty years of age, he never failed to find them; in subjects above that age they were sometimes absent. On the other hand, accessory thyroids were rarely found in young children, but were comparatively frequent in middle-aged and elderly subjects. The disappearance of parathyroids with advancing years makes Forsyth doubt the physiological importance sometimes attributed to them.

P.

Bacteriological Examination of the Blood after Death.—Otten has made a bacteriological examination (*Virchow Archiv.*, 1906, Bd. 184, S. 284) of the blood in 200 corpses, and has only found it sterile in 84 out of that number, that is, in 42 per cent. The very numerous positive results are to be explained by the fact that he did not examine all cases, but only those in which bacteria were expected to be present. Streptococci were most often found, 69 times alone, and 13 times in company with other organisms. Staphylococci and B. coli were only occasionally found. The blood was taken in each case from the right side of the heart, and very thorough precautions were taken to avoid infection. In a large number of cases the same organisms were found postmortem as during life, except that their number was greatly increased after death.

M.

Pancreatic Changes Associated with Liver Cirrhosis.—Very few observations exist with reference to the condition of the pancreas in cases of cirrhosis of the liver, but various associated pathological changes have been recorded from time to time. Among these may be mentioned: (1) Increase in the amount of connective tissue present, with proliferation in number of the contained capillaries. (2) Thickening of the walls of the pancreatic arteries going on in many places to complete obliteration. (3) Old and new hæmorrhages scattered through the organ and giving rise to pigmentary deposits. (4) Atrophy of Langerhans islets and replacement of them by connective tissue. (5) Fatty degeneration of acini, and overgrowth of elastic tissue. Sands has recently investigated 23 cases of liver cirrhosis (*Zeitsch. f. Heilk*, Bd. 27, H. 1), and has found the above changes in some of the cases, but has been unable to establish any definite connection between these changes and the degree of liver cirrhosis. In some cases the pancreatic cirrhosis was acinar, and in some interacinar. No difference was found between the cases associated with atrophic and hypertrophic liver cirrhosis respectively.

M.

Compensation in Tricuspid Incompetence — Many writers believe that there is no compensatory mechanism in cases of failure of the tricuspid valves. Sadler has investigated the matter (*Wiener Klin. Woch.*, 1906, No. 31), both by examining the records of reported cases, and by experimentally producing tricuspid incompetence in rabbits. He points out that it is quite out of the question for any change to occur on the left side of the heart, but maintains that hypertrophy of the right ventricle is a constant feature. This hypertrophy manifests its influence most during diastole, when the increased suction power thereby given to the chamber enables it to draw the venous blood with considerable force into its cavity. Another compensatory effect depends on the liver elasticity. The liver blood vessels are distended by a regurgitant flow during systole, but during diastole, the elasticity asserts itself and helps in driving the blood back again towards the heart.

M.

Physiological Action of Blue Light. — Dr. Cavalié of Bordeaux, was the first to point out that the different spectral colours seem to produce specific impressions on animals and plants, and found that blue rays in particular exerted a sedative influence. So much is this the case that fixation of the eyes for a few seconds on blue light produces sufficient anæsthetisation of the face to permit of the performance of minor operations, such as teeth extraction. Dr. Redard has employed the method and reports the technique that he now follows (*La Quinz. Therapeut.*, March 25th, 1907). He finds that for success it is necessary to exclude all other light rays, and to keep the patient under the influence of blue rays for about three minutes. In this way local insensibility to pain is produced, and lasts for about 30 seconds. The writer has now tried it in about 40 cases and usually with success. He does not discuss the cause of the anæsthesia, but at first sight it would seem to be merely an example, and a bad one, of hypnotic insensibility.

M.

Experimental Epilepsy.—Drs. Zimmern and Dimier report their experiments on the production of epileptiform seizures in animals (*La Quinzaine Therapeutique*, March 10th, 1907). They find that when interrupted currents of low tension are employed, and the electrodes placed with one on the back and the other on the front of the head, a series of phenomena develop as the intensity of the current is increased. At first the animal falls on its back and becomes deeply comatose. Then if any change is made in the regularity of the interruptions clonic spasm of the limbs, and glottis ensue; these last giving rise to an "epileptic" cry. The best results are obtained when the negative pole is applied to the head. If after the production of coma, the current be further increased in strength, death will result from inhibition of the cardiac and respiratory centres. The resemblance to human epilepsy is increased by the fact that the temperature becomes raised during the convulsive period. These experiments were carried out in rabbits and dogs and were successful in both.

MEDICAL NEWS IN BRIEF.

Royal College of Surgeons.—New Fellows and Members.

A quarterly meeting of the Council of the Royal College of Surgeons was held at the College yesterday, Mr. Henry Morris, F.R.C.S., President, in the Chair. Dr. Alex. Hill, M.A., Master of Downing College, Cambridge, and Professor Arthur Thomson, M.A., M.B., of the University Museum, Oxford, were elected Fellows of the College. The following candidates, having passed the required examinations and conformed to the bye-laws, were admitted members of the college: Robert Dixon Brown, of St. Thomas's Hospital; Charles Grange McGreer, of Queen's University, Kingston, Canada and Middlesex Hospital; and Charles Edward Waldron, of the London Hospital. At this meeting, the award of the Jacksonian Prize for 1906 was announced, Dr. Donald J. Armour, F.R.C.S., being successful.

Mr. Frederic Eve, surgeon to the London Hospital, was elected a member of the surgical section of the Board of Examiners in Dental Surgery. It was decided to add Leys School, Cambridge, and Trent College, Long Eaton, to the list of institutions recognised by the conjoint examining board for instruction in chemistry, physics, and biology.

The President stated that Professor William Wright's Hunterian Lectures on "The Prehistoric and Early Historic Inhabitants of England," which were recently postponed, would be delivered on May 6th, 8th, and 10th.

Mr. J. Ward Cousins, the representative of the college on the Central Midwives' Board, reported the proceedings of the Board during the past year, and informed the Council that, during this period, the Board have recognised 48 training schools in England, six in Scotland, and seven in Ireland, whilst the number of teachers appointed amounts to 144. The

Board have held examinations in London, Bristol, Manchester, and Newcastle-on-Tyne. 1976 candidates entered for the examinations; of this number 1,527 received their certificates, and 449 were unsuccessful. The number of certified midwives on the roll amounts to 24,549. The best thanks of the Council were given to Mr. Ward Cousins for his services as the representative of the College on the Board.

The President was elected to attend the centenary celebration of the Geological Society, which takes place in September next, as the delegate of the College.

Royal Maternity Charity.

THE annual meeting of governors of the Royal Maternity Charity of London was held at 31, Finsbury Square, E.C., on April 9th, Mr. C. Barham, C.C. (chairman), presiding. The report of the Medical Committee showed that the number of cases treated in 1906 was 2,651. The number of children born was 2,700, and the number of deaths 43—this mortality representing a rate of 15.92 per 1,000. Eight mothers had died, the rate in their case being 3.01 per 1,000. The deaths were non-preventible, and the low death-rate was a matter for congratulation as evidence of medical skill. The secretary of the society was working in touch with the Medical Department of the London County Council, and with the Central Midwives' Board. Mr. J. Whittington, in moving the adoption of the report, said the charity's midwives were highly skilled, and one of them was once engaged by the Empress of Germany. The motion having been seconded by Mr. R. J. Tasker, the Chairman said that the public had not responded to the appeal of the charity as it should have done. The festival they had held since the last meeting was not much of a success, although they thought that a hundred and fiftieth anniversary would have appealed to the public. When he was Lord Mayor they would all have a good time at the Mansion House. (Laughter.) He was very much hurt that the Lord Mayor did not invite them there last time. The reports were unanimously adopted, and the officers and committee were re-elected, with certain additions.

Inquest on a Medical Man.

ON April 5th an inquest was held before the deputy-coroner at the Turf Hotel, Winlaton, on the body of Dr. Colin Mansfield Campbell, whose death occurred at his residence, Front Street, Winlaton. Dr. Guthrie Raynes Plante, of Blaydon, to whom deceased acted as assistant, said that Dr. Campbell was about 35 years of age, and had resided at Winlaton for five years. On Sunday last witness had a long conversation with Dr. Campbell upon both professional and personal matters. Deceased was then rather depressed, although when witness had previously seen him he was all right. Deceased did not complain on Sunday, but he could not see his way clear in regard to his own personal matters. These were nothing serious—some little matters of finance. On Wednesday morning witness was called in to see Dr. Campbell at about a quarter to eight o'clock. Deceased was upstairs in bed, and was unconscious. Witness came to the conclusion that deceased was suffering from opium poisoning—an overdose of opium in the form of morphia or laudanum, or something of that. Deceased died at half-past nine o'clock on the same morning. Replying to further questions, Dr. Plante stated that he did not think Dr. Campbell was in the habit of taking opium. Deceased was not a very temperate man. He was married, but did not live with his wife. There was nothing in deceased's financial matters that could not have been put right. He enjoyed good health, and witness had never heard him threaten to do away with himself. Witness was of opinion that deceased had taken the morphia or opium to make him sleep. He was satisfied that it was a case of deceased having taken an overdose. A verdict was returned that death had resulted from the effects of an overdose of some narcotic poison, probably taken for the purpose of inducing sleep.

Poisoning by Prunes.

A REMARKABLE instance of poisoning, affecting seven members of a family, occurred in the northern district of Glasgow on April 6th. After partaking of some prunes as part of the dessert at dinner-time they suddenly became very ill. The names of the persons affected are: Jane Muir (23), Maggie Muir (19), Thomas Muir (15), Agnes Muir (10), David Muir (7), Flora Muir (6), and Mabel Muir (4). They are the family of Robert Muir, master plumber, residing at 13, Holmhead Street, Glasgow. The casualty surgeon, who examined the sick persons, stated that he was able to say they were out of danger. In his opinion they were suffering from the effects of some irritant poison, which probably existed in the dish of prunes of which they ate.

School Hygiene Congress.

A PRELIMINARY programme for the second international congress on school hygiene has been issued. The congress, of which the King is patron, is to be held at London University during the first week in August under the presidency of Sir Lauder Brunton. Delegates are to attend the congress from the United States, Austria, France, Canada, Denmark, Germany, Finland, Greece, Holland, Japan, Italy, South Africa, Sweden and Switzerland. On Sunday, August 4th, special services will be held, and on Bank Holiday there will be a reception of the delegates, followed by the President's inaugural address. Afterwards sectional meetings will be held for the discussion of various questions connected with the instruction of teachers and children in hygiene. Garden parties, entertainments, and excursions are to be held later. It was determined at the first congress, held in Nuremburg in 1904, that the educational and hygienic movement going on in the British Empire should be acknowledged by holding the next meeting in London, and probably the congress of 1910 will be held in France.

Friendly Societies' Medical Alliance Conference.

MEMBERS of the Friendly Societies' Medical Alliance deputed to attend the annual conference arrived in Exeter on March 30th. A reception was held at the Arcade Hall, where the visitors were welcomed by Mr. H. W. Loram and Mr. W. Amery (respectively chairman and vice-chairman of the Council); and Mr. C. E. Hopping, secretary. All the delegates expected, save three, were reported as having arrived.

A cordial welcome to Exeter was offered to the delegates by members of the local branch. The reception extended from half-past six to half-past nine, and at an interval in the evening refreshments were served. Members of the Alliance spent the first day as they pleased, there being no official programme. Some visited places of interest in the city, some went for the day by the seaside, and others availed themselves of inland trips. On Monday, prior to the opening of the Conference at eleven o'clock, the members of the Alliance were taken over the Cathedral by Chancellor Edmonds, and afterwards they visited the Guildhall, where the Town Clerk showed and described the civic regalia. The most contentious matter of business before the Conference was a proposal from Leeds to strengthen the defence fund. A visit was paid by the Mayor of Exeter to the Conference, which he warmly welcomed.

PASS LISTS.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow.

THE Quarterly Examinations of the above Board, held in Edinburgh, were concluded on the 12th inst., with the following results:—

First Examination (*Four Years' Course*).—Miss Adeline Watts passed the examination.

First Examination (*Five Years' Course*).—Of 27 candidates entered, the following 11 passed the examination: Morris Greene (with distinction), Hillary D. Brown, Joseph F. Sweeney, Alfred M. Billings, James

Mitchell, Arthur C. Price (with distinction), Francis L. Kennefick, Tiruvallur K. Jayaram, Alexander L. Gibbon, Howard A. Whitehead, and Adolph B. Kramer, and 6 passed in biology and 2 in chemistry.

Second Examination (Five Years' Course).—Of 25 candidates entered the following 12 passed the examination: Dakshina Ranjan Das Gupta, Robert W. A. Brown, Harold G. Chouler, William T. Lawrence, George N. Groves, John N. Robson, Richard Parry, John Young (with distinction), Thomas Crawford, Beatrice Coxon, Philip G. Phillips, and Charles W. Kay, and 1 passed in anatomy and 2 in physiology.

Third Examination (Five Years' Course).—Of 21 candidates entered the following 12 passed the examination: James Reid, Louis N. Robertson, William R. Mackenzie, Frederick Watson, Thomas G. Shand, Jacobus du Toit Malan, Arthur E. James, Shridhar C. Jog, William McKee, Leslie O. S. Poidevin, William F. Mitchell, and Behram S. Photographer, and 2 passed in materia medica.

Final Examination.—Of 50 candidates entered, the following 23 passed the examination, and were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P.&S.G.: D. Terener de Kretser, Taylor D. Murison, George M. Williamson, Ronald M. Liddell, William McKee, Francis L. Scott, George E. Anderson, Arthur H. Bloxsome, Arthur P. O'Connell, Harold H. Babington, Wilfrid Chambers, James Ferguson, Oney M. Gericke, Arnold McMillan, Howard B. Stephenson, David Golding, John H. Simpson, Vamanrao A. Vijayakar, Douglas L. G. Radford, Sureswar Sarkar, Robert M. Jones, T. Canagasaby, and Madan Lal Puri, and 5 passed in medicine and therapeutics, 3 in surgery and surgical anatomy, 7 in midwifery, and 7 in medical jurisprudence.

University of Glasgow.

THE following have passed the Third Professional Examination for the Degrees of M.B. and Ch.B. in the subjects indicated (P., Pathology; M., Medical Jurisprudence and Public Health):—

David Anderson (P.); William Anderson (P., M.); Thomas Archibald (P.); William Barr (P., M.); Charles Bennett (P., M.); John Blakely (P.); John Lindsay Boyd (P., M.); James Nimmo Brown, M.A. (P.); William Barrie Brownlie (P.); Hector Mackay Calder (P., M.); James Carrick (P., M.); Matthew Ignatius Thornton Cassidy (P.); Donald Clark (M.); Donald James Clark (P.); James Cook, Partick (P., M.); John Cruickshank (P., M.); Neilson Davie (P.); Walter Dawson (M.); James Cowie Dick (M.); Arthur Drummond Downes, M.A. (P., M.); William Miller Fairlie (P., M.); Walter Gilmour (P., M.); Josiah Stranaghan Harbinson (P., M.); Michael Harkin (P., M.); Thomas Harkin (M.); John Mitchell Henderson (P.): Stephen John Henry (P., M.); Benjamin Hutchison (P., M.); John Lang (P., M.); Frank Crombie Macaulay (P.); Joseph Glaister M'Cutcheon (M.); Coll Macdonald (P., M.); William M'Kendrick (P.)· Murdo Duncan Mackenzie (P.); Thomas Cooper Mackenzie (M.); Francis William Mackichan (P.); William Campbell Mackie (P.); James Walter M'Leod (P., M.); John MacMillan (P., M.); Peter Russell M'Naught (P., M.); Donald Irvine M'Naughtan (P., M.); David Manton (P., M.); Frank Needham Marsh (P.); William Matheson (P., M.); Kenneth Chisholm Middlemiss (P., M.); Allan Frederick Miller (P.); Robert M'Kenzie Morison, M.A. (P., M.); James Muir (P., M.); William Aikman Muir (P.); Archibald Campbell Munro (P., M.); Charles Sutherland M'Kay Murison (P.); Albert Rutherford Paterson (P., M.); Adam Patrick, M.A. (P., M.); Ralph Montgomery Fullarton Picken, B.Sc. (P.); Murray Purvis (P., M.); Edward Quigley (P., M.); Richard Rae (P.); Henry Nimmo Rankin (P.); Nicol M'Nicoll Rankin (P., M.); Murdoch Mann Roger (P.); Neil Campbell Scott (P., M.); James Brown Sim (P.); James Alexander Stenhouse (P.): Donald Stewart (P., M.); Hugh Cochrane Storrie (P.); David Taylor (P.); John Shedden Thomson (P., M.); Robert Macnair Walker (P., M.); Thomas Charles Dalrymple Watt (P., M.); Thomas Macknight Watt (M.); Hugh White (P.); David M'Gruther Wilson (M.); William Mitchell Turner Wilson (P., M.); Hugh Young (P.). Women: —Margaret Baird Sproul Darroch (P.); Mabel Foley (P., M.); Annie M'Corrie (P.); Winifred Margaret Ross (P.); Jessie Capie Russell (P., M.).

At the recent professional examination for the degrees of M.B. and Ch.B. the following candidates passed with distinction in the subjects indicated:—

First Examination—In Zoology and Chemistry—Thomas Stewart Barrie, William M'Murray, James Eric Paterson. In Physics and Chemistry—William Larmour Anderson. In Botany—Charles Averill. In Zoology—Thomas Adam, M.A.; James Turner Brown, Charles Cameron, Kinloch Falconer, John Radcliffe Grice, M.A.; James David MacKinnon, Andrew Bruce MacLean, William Wyllie MacNaught, Farquhar Matheson James Alexander Hamilton Telfer, Alexander Stewart Wilson. In Physics—Andrew Scobie Findlay, John Mitchell. In Chemistry—Alexander Baird, John Campbell, Malcolm Sommerville, William Tudhope, Gordon Alexander Valentine.

Second Examination—In Physiology—Charles Duguid, M.A.; Donald Fisher, George Fletcher, M.A.; William M'Adam, M.A.; John Hart M'Nicol, Mary Cochrane Mitchell, Margaret Eason Robertson, Alfred Roemmele, William Wilson Rorke, Richmond Steel, David Campbell Suttie, James Lachlan Ure. In Materia Medica and Therapeutics—George Macleod, M.A.

Third Examination—In Pathology and in Medical Jurisprudence and Public Health—John Cruickshank, Robert Macnair Walker. In Pathology—Charles Bennett, William Barrie Brownlie, Peter Russell M'Naught, Ralph Montgomery Fullarton Picken, B.Sc. In Medical Jurisprudence and Public Health—Benjamin Hutchison, Archibald Campbell Munro, Adam Patrick, M.A.

London School of Tropical Medicine.

The following candidates passed the Examination in Tropical Medicine during the session January to April, 1907:—Major F. R. Ozzard, I.M.S., M.R.C.S., L.R.C.P., 1888, Capt. T. G. N. Stokes, I.M.S., M.B., B.Ch., B.A.O., Trin. Coll, Dublin, 1898, J.M. O'Brien, M.R.CS., L.R.C.P., 1902 (Colonial Service), O. Berkeley Hill, I.M.S., M.B. (Oxon.), 1906, Capt. J. W. F. Rait, I.M.S., M.B., B.S. (Lond.), 1896,.L.S.A. 1896, A. W. Atkinson, M.B., B.Ch. (Edin.), 1906 (Colonial Service), [with distinction]. M. Gamble, M.D. (Victoria), 1904, F. W. Woolrabe, M.R.C.P., F.R.C.S., (Edin.), 1895, D.P.H. (Dublin), 1900, E. G. H. Weir, M.D., C.M. (Toronto), 1899, M.R.C.S., L.R.C.P., 1903 (Colonial Service), A. Orgnieri, M.D. (Torino), 1905, C. W. McLeay, B.A. (Tor.), 1895, M.D. (West.), 1899, M.R.C.S., L.R.C.P.,1904 (Colonial Service), E. W. Wood-Mason, M.B., C.H. (Aber.), 1898 (Colonial Service), Miss A. M. Cowan, M.B., Ch.B. (Edin.), 1906, R. W. Orpen, L.R.C.S. and P. (Ireland), 1900 (Colonial Service), F. McF. W. Pollard, M.B., B.S. (Lond.), 1904, M.R.C.S., L.R.C.P., 1904 (Colonial Service), Miss A. M. Clark, M.B., B.Ch. (Glas.), 1900, B.Sc., 1898, W. N. Alexander, L.R.C.P. and S. (Edin.), 1904 (Colonial Service), H. O'Hara May, M.D. (Dublin), 1903 (Colonial Service).

Conjoint Examinations in Ireland.

The following candidates have passed the First Professional Examination held by the Royal College of Physicians and the Royal College of Surgeons:—J. S. McHugh (with Honours), C. J. Bourke, T. Buckley, F. M. J. Byrne, A. D. Clanchy, P. Daly, J. A. Dowling, F. J. Eager, J. T. Hill, N. Keating, P. Murphy, F. J. McCarthy, A. McGrath, J. Nally, C. H. Oliver, T. P. O'Reilly, D. P. H. Pearson, A. A. Russe, M. V. Sexton, J. P. Shorten, H. H. K. Sparrow, T. M. Thomson, F. W. Warren, F. Webster, P. J. Wigoder, P. O'C. White.

NOTICES TO CORRESPONDENTS, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

Graphic.—(1) On the contrary, there has been a constant decline in the death and discharge rates at lunatic asylums. Indeed, it is calculated that if the discharge rate during 1903-1905 had been the same as that of 1873-1877 the total number of the insane under care would have fallen by 1,578; instead of which it increased 7,236. (2) The increase is chiefly due to the large number of such dements as were formerly looked after at home.

ETHER IN THE GOAT.—AN AMUSING ANECDOTE.

Professor Hare is responsible for the following: When ether was first introduced, a certain Jefferson professor was of the opinion that either not enough ether could be given to produce anæsthesia, or that so much would be required that the patient's life would be threatened. He determined to conduct an experiment before the class in the old college building, and secured a pugnacious and virile billy goat as the victim. After a lengthy and vigorous argument between the goat and a number of students, the animal was placed upon the table and duly anæsthetised. In a few minutes the goat appeared to be breathing its last. The Professor dwelt upon the dangerous use of the new drug, and the class adjourned for a lecture. Hardly had they started down the stairs, which were narrow and precipitous, than the goat, which had come to, appeared in their midst and viciously butted them in all directions.—*The Jeffersonian.*

M. T.—Laborde's method of restoring animation consists in making rhythmical traction on the tongue. The organ can be held by forceps or by the fingers, and is drawn slowly in and out of the mouth. It is useful in children, and in cases of injury in which the ribs are fractured.

Motorist.—Similar symptoms have been described in a Paper in the *Lancet*, July 7th, 1906. The patient was a motor-'bus driver and complained of persistent pain in the right hip and back. The limb was spastic and the reflexes were exaggerated. At first there was hyperæsthesia, but later anæsthesia. Recovery took place in about a month under symptomatic treatment. We should be glad to have details of your case for publication, as the subject is a new and interesting one.

Tropicus.—Experiments on man have been recorded in connection with the dysentery bacillus which seem to point strongly to its specific pathogenicity. One was accidental, the experimentor contaminating his mouth with some fluid culture, and suffering shortly afterwards from a smart attack of dysentery. The other was made in the Philippine Islands on a condemned prisoner. A similar attack ensued almost immediately, and the organism was recovered from the stools.

Meetings of the Societies, Lectures, &c.

Wednesday, April 17th.

Royal Microscopical Society (20 Hanover Square, W.).—8 p.m.: Exhibition of Slides of Foraminifera by Mr. A. Earland. Paper:—Mr. E. M. Nelson: On the Podura Scale.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. L. Mummery: Clinique. (Surgical). 5.15 p.m.:—Lecture:—Dr. N. Tirard: Some Forms of Pnuemonia.

North-East London Post-Graduate College (Tottenham Hospital, N.).—Cliniques:—2.30 p.m.: Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Out-patient (Dr. Whipham).

Thursday, April 18th.

Harveian Society of London (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m.: Papers:—Mr. Jaffrey: A Case of Ulcerative Colitis treated by Operation under the care of Dr. Latham and Mr. Jaffrey. Dr. L. G. Guthrie: Some Nervous Affections of Childhood.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. E. Clarke: The Fundus Oculi in Health and Disease (with lantern slides).

North-East London Post-Graduate College (Tottenham Hospital, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques: Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson). 3 p.m.: Medical In-patient (Dr. Chappel).

Friday, April 19th.

Society for the Study of Disease in Children (11 Chandos Street, Cavendish Square, W.).—5 p.m.: Clinical Evening for the Exhibition of Cases followed by Discussion. Patients in attendance at 4.30 p.m.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. M. Yearsley: Clinique. (Ear.)

North-East London Post-Graduate College (Tottenham Hospital, N.).—9.30 a.m.: Clinique. Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. Leslie).

Monday, April 22nd.

Odontological Society of Great Britain (20 Hanover Square, W.).—8 p.m.: Communication:—Mr. J. F. Colyer, L.R.C.P., M.R.C.S., L.D.S.Eng., on "Some Specimens recently presented to the Museum of the Society." Paper:—Mr. Harold Simms, M.D., Ch.B.Vict., L.D.S.Eng., on "Some Observations on the Bacteriology of Pyorrhœa Alveolaris." The Communication and Paper will be illustrated by lantern slides by means of the Epidiascope.

Vacancies.

West Riding Asylum, Wakefield.—Pathologist and Assistant Medical Officer. Salary £140 per annum, with board, furnished apartments, washing, and attendance. Applications to the Medical Director.

Cornwall County Asylum, Bodmin.—Third Assistant Medical Officer.—Salary £140 a year, with furnished rooms, rations, laundry, and attendance. Applications to Medical Superintendent.

Birkenhead Union.—Resident Assistant Medical Officer. Salary £120 per annum, with board, washing, and apartments. Applications to John Carter, Clerk to the Guardians, Poor-law Offices, Birkenhead.

Swansea Union.—Assistant Medical Officer. Salary £200 per annum. Applications to Llewn. Jenkins, Clerk, Union Offices, Alexandra Road, Swansea.

Fife District Asylum, Cupar-Fife.—Junior Assistant Medical Officer. Salary £120 per annum, with rooms, board, and attendance. Applications to the Medical Superintendent.

North Staffordshire Infirmary and Eye Hospital, Hartshill, Stoke-on-Trent. House Physician. Salary £100 per annum, with furnished apartments, board, and washing. Applications to the Secretary and House Governor.

Bradford Royal Infirmary.—House Surgeon. Salary £100 per annum, with board and residence. Applications to John Barron, Secretary.

Manchester Hospital for Consumption and Diseases of the Throat and Chest.—Assistant Medical Officer. Salary £100 per annum, with board, apartments, and laundry. Applications to C. W. Hunt, Secretary, Hardman Street, Deansgate, Manchester.

Lancashire County Asylum, Winwick, Warrington.—Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, attendance, and washing. Applications to the Medical Superintendent.

Cossham Memorial Hospital, Kingswood, Bristol.—House Surgeon and Resident Medical Officer. Salary £100 per annum, with board, apartments and laundry. Applications to John Henshaw, Secretary.

Appointments.

Angelis, A. A., M.D.Athens, L.S.A.Lond., Clinical Assistant to the Evelina Hospital for Children, Southwark.

Black, Edward Hamilton, M.B., Ch.B.Edin., Assistant House and Visiting Surgeon to the Stockport Infirmary.

Galletly, J., M.B., M.S.Edin., Certifying Surgeon under the Factory and Workshop Act for the Bourne District of the county of Lincoln.

Quirke, J., L.R.C.P. and S.Irel., Certifying Surgeon under the Factory and Workshop Act for the Inistioge District of the county of Kilkenny.

Riddell, W. H., M.B., Ch.B.Edin., House Surgeon at the Staffordshire General Infirmary, Stafford.

Rose, Frank A., M.R.C.S., L.R.C.P.Lond., Assistant Surgeon to the Throat Department at St. Bartholomew's Hospital.

Births.

Drake.—On April 12th, at Chilworth, Redhill, the wife of E. C. Drake, M.R.C.S., L.R.C.P., of a daughter.

Gardner-Medwin.—On April 10th, at 22 High Street, Wavertree, Liverpool, the wife of Frank M. Gardner-Medwin, M.R.C.S., L.R.C.P. of a son.

Langley.—On April 11th, at Kiln House, Tadley, near Basingstoke, the wife of W. J. Langley, L.R.C.P., L.R.C.S., of a daughter.

Pearson.—On April 9th, at Croft House, Owston Ferry, Doncaster, the wife of Francis J. Pearson, M.R.C.S.Eng., L.R.C.P.Lond., of a son.

Steele.—On April 11th, at Sydney House, Chiswick, the wife of Charles Francis Steele, M.B.Lond., of a daughter.

Thom.—On April 5th, at Simla, India, the wife of Major G. O. St. C. Thom, R.A.M.C., of a son. (By cable.)

Marriages.

Crosbie—Crosbie.—On April 11th, at St. Finian's, Greencastle, Pierce Leslie, F.R.C.S., R.N., eldest son of Leslie Crosbie, M.D., Ardfert, county Kerry, to Winifred, fourth daughter of the late Pierce Crosbie, Esq., J.P., Greencastle, county Donegal.

Nitch—Bryden.—On April 10th, at St. Barnabas, Addison Road, Cyril A. R. Nitch, M.S., F.R.C.S., 69 Harley Street, London, son of George H. Nitch, 22 Victoria Square, S.W., to Amy Annie, elder daughter of the late Surgeon-Major J. L. Bryden, M.D., I.M.S., and of Mrs. Bryden, 8 Addison Gardens.

Phelps—Parker.—On April 11th, at Lapworth Church, John Henry Dixon Phelps, M.B., B.Ch.Oxon., of Scorton, Yorkshire, to Lucy Olive, younger daughter of Reginald Parker, of Lapworth.

White—Mason.—On April 12th, at St. Margaret Church, Stanford-le-Hope, by the Rev. J. Russell, George Fawcett White, M.D., eldest son of H. Bantry White, M.A.I., Ballinguile, Donnybrook, to Nora Dorothy, second daughter of Robert Mason, of Pitsea Hall, Essex.

Deaths.

Astley.—On April 12th, at 29 Marine Parade, Dover, Edward Farrand Astley, M.D., J.P., in his 96th year.

Lewis.—On April 8th, at Kingscliffe, Northamptonshire, of pneumonia, Thomas White Lewis, M.D.Univ.Dub., second son of the late J. M. Aylward Lewis, J.P., of Ballinagar, co. Galway, and Mrs. Lewis, 42 Morehampton Road, Dublin, aged 52 years.

Mahaffy.—On April 10th, at Maidenhead, Susan Frances Mahaffy, aged 77 years, widow of Edward Mahaffy, M.D., C.B., Surgeon-General, Indian Medical Service.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIV. WEDNESDAY, APRIL 24, 1907. No. 17

NOTES AND COMMENTS.

Barber Midwives. THE traditional link that used to bind the barbers and the surgeons together was brought to mind in a case lately tried by the Lord Chief Justice and some of his colleagues sitting in the King's Bench Division to hear an appeal brought by a midwife, Mrs. Feldmann, against a resolution of the Central Midwives' Board removing her name from their roll. Mrs. Feldmann, it would seem, enjoyed to so large an extent the confidence of her neighbours that her services were in request too frequently for her to be able to give personal attention, and on two occasions when unable to go to cases she deputed her husband. This gentleman, it was said, in evidence, possessed a Russian medical diploma, but whether by reason of the disturbed state of his native land, or because a prophet is without honour in his own country, or through natural predilection, he decided to abandon the practise of medicine in favour of that of hair-dressing and in that capacity he not only gained an honest livelihood, but won the affections of the local midwife. What then more natural that when through the press of professional duty his wife could not fulfil all her appointments, he should act as a stop-gap? The arrangement, however, coming to the ears of the Central Midwives' Board, and Russian medical diplomas not ranking as a qualification for entry to their register, the wife was struck off the rolls and her certificate cancelled. Happily, but rather unexpectedly, the Court held that they were justified in doing so, and it may be hoped that the barber will now stick to his block. Unlike removal from the medical register, the striking of a woman off the Midwives' roll disqualifies the offender from pursuing her calling.

Caprice of the C.M.B. Now, although it is very proper that the offence of "covering" should be severely dealt with, it passes the the wit of man to deduce any sort of consistency out of the policy of the Central Midwives' Board, either as regards the exercise of disciplinary powers or of those of general administration. All sorts of grave offences are passed over with cautions and without any good reason appearing why the offenders should not be vigorously dealt with, and similar caprice marks the recognition of institutions as training schools. At a recent meeting of the Poor Law Unions Association Dr. J. M. Rhodes drew attention in a forcible manner to the utter want of method shown by the Board in sanctioning centres for instruction. He mentioned the fact that only nineteen schools had been approved for the whole of the fifty-two counties of England and Wales, and that whereas in a sparsely populated agricultural county like Gloucestershire five schools were allowed, in crowded industrial districts such as Durham and Staffordshire not a single one had been recognised. Then, too, there lurks under their actions an extraordinary jealousy of Poor Law Infirmaries which, if properly utilised, should form natural training centres. As it is, almost any voluntary institution can be approved, whilst the difficulty guardians experience in getting their infirmaries recognised is immense. The Lord President of the Council, in replying to a deputation, spoke of the Midwives' Board as an "irresponsible body." So *de jure* it is, and so *de facto* it likes to prove itself.

Midwifery Fees at Rotherham. THE question of payment of fees to medical men called in by midwives is still in a most unsatisfactory state. The Rotherham Borough Council, recognising the gross injustice of the position of affairs, lately decided to be responsible to practitioners for fees incurred in this way, as Liverpool, Manchester, and Cardiff have already made themselves responsible. There was, however, a good deal of opposition to the resolution, and it was found to be illegal in the form it passed in. Consequently the movers of a rescinding motion found no difficulty in getting the resolution nullified. One of the speakers stated that so far as he could ascertain the medical men in the town were opposed to payments being made by the Council, but probably in this instance the wish was father to the thought. But it is important that the matter should be thoroughly sifted and looked at in all its bearings before any decisive action is taken, for it must not be forgotten that if people learn to know that by employing a midwife at five shillings or seven-and-sixpence they can be assured of the services of a trained woman who, in emergency, can obtain the services of a doctor to be paid by the public authority, there is more than a danger that a large number of thrifty people who now save up a guinea to pay their own medical man for a confinement, will gradually come to fall back on the cheaper method. So that it is advisable that any fee paid by a public authority should be recoverable from the people who have incurred it, if in the opinion of the authority they are in a position to pay.

Isolation Dances. The Bristol Health Committee have been engaged in a long and anxious discussion, and considering the gravity of the matter before them it can only be remarked that they must have been been guided by an unusually high sense of public duty to have devoted so much of their time to it. The question, indeed, was none less than whether the nursing staff at their isolation hospital should be allowed to engage in the pastime of dancing once every two years. It came out that though the individual members of the committee knew that such a festivity took place, yet—heinous offence! —it had not been officially reported to the committee, and the chairman had not been asked if he approved of the list of guests! One member wished to know if this curious form of entertainment was indulged in "throughout England," and several spoke heatedly about squandering the rates in such a fashion. The burden thus untimely thrown on the rates was shown to be a matter of half a sovereign, as the nurses themselves found everything except bread and butter; and as the half sovereign was incurred once in two years, one hardly imagines that the ratepayers would groan under the load. Another great source of anxiety to the Committee was that eleven of the guests who came from a distance were given the hospitality of a bed for the night, under the supervision of the medical superintendent, and several members of the Committee learned with surprise that it was usual for dancers not to retire very early. Eventually it was solemnly determined to frame rules to regulate the conduct of this dangerous pastime, and the Committee, after sitting some three hours, adjourned. It is fair to assume that the health of Bristol is safe in the hands of such punctilious gentlemen, and that what they lack in humour is made up for by some less conspicuous qualities.

Eye Glasses for Schools. In New York, as in this country, considerable attention is being directed to the eyesight of school children, and it is estimated that 36,000 of them, representing six per cent. of pupils attending elementary schools, have defects of vision that require treatment. A committee has been working on the subject and it has now recommended that the Board of Education to incur the cost necessary for examining the children's eyes systematically. This, it is recognised will be very large, £5,000 alone being required for suitable premises, to say nothing of the salaries of the surgeons employed. But the proposal that strikes the British readers as most curious is that the Board shall provide the children with free eye-glasses! Spectacles, we could understand, and perhaps it is only the American way of putting things, but the mind rather quakes at the idea of what would happen if the happy Board School child were given the run of a stock of free eye-glasses. Even Mr. Chamberlain in all his glory would not be arrayed like one of these.

LEADING ARTICLE.

THE FRAUDULENT DRUG TRADE.

Under the above heading the *Pharmaceutical Journal* publishes an amusing tirade against the Medical Press and Circular, and what it is pleased to style our "reckless crusade against proprietary medicines." The writer of the article says that, however worthy our object may be, yet "no reasonable person can fail to see that the manner of conducting the campaign is as silly as it is useless." In support of that sweeping statement he quotes a former "difficulty" in which the Medical Press was involved with *Truth*, from which he holds we "emerged very much the worse" (*sic.*). We presume that this writer claims to be considered a "reasonable person," so that the "prophet of Covent Garden," as he calls us with easy elegance of phrase, may venture to remind him of the main issue involved in the dispute to which he refers. The Medical Press and Circular pointed out on several occasions that *Truth* had for a long time inserted in its columns an advertisement from one Mrs. Adair, offering certain "Ganesh straps," stuffed with fragrant Eastern herbs, at a guinea and a half apiece, for the cure of wrinkles. There were other "Ganesh" remedies of a kindred nature, such as "muscle oil," to which we drew the attention of our contemporary. We were favoured with many columns of fierce invective in reply by *Truth*, but from beginning to end of its articles not a single reference was made to the crucial point of the Ganesh straps and the Ganesh remedies. If that convinces the "reasonable person" of the *Pharmaceutical Journal* that our arguments were satisfactorily met and demolished, then we fear that the peculiar nature of his intellectual methods would render further argument futile. In support of his own statement that the Medical Press possesses the "blind belief" that it alone is opposed to fraud we have the following: "It" (that is, ourselves) "seems to be content with a smattering of trivial information wherewith to blunder along in its blustering campaign, sledgehammering everything and everybody that it takes into its head to hit." This sentence affords an example of the swash-bucklering style of invective that in the eyes of our contemporary clearly assumes the position of strong and sustained argument. It is of course impossible to undertake any discussion conducted on simple lines of noisy clamour. At the same time it is of interest to enquire why an attack upon fraudulent drugs should so excite the anger of a respectable journal devoted to the interests of the drug trade. So far as we can gather the writer is annoyed mainly because we have stepped in to do a work of exposure that should belong to himself and to the chemists and druggists. He may rest assured that the medical journals no less than the medical profession will hail with acclamation any help in the suppression of the nefarious trade in quack remedies, come from what quarter it may. "Chemists and druggists," he writes, " would form the most powerful ally of any properly-conducted movement which has for its object the suppression of the sale of remedies of a fraudulent character; but the policy of our contemporary seems to be to alienate the sympathy of everybody who could possibly be of service in the campaign." The direction of this charge leads us to refer to the particular paragraph which has upset the equilibrium of the *Pharmaceutical Journal.* The rock of offence is a short leader that appeared in our issue of April 10th, under the title of "The Fraudulent Drug Trade." The text was an advertisement culled from a daily newspaper of a disinfectant claiming great and unrivalled powers, but shown by a correspondent " Analyst " to be practically worthless as a disinfectant and to be foisted on the public with the help of an absolutely worthless, false and misleading chemical test. We fancy that most chemists and druggists would welcome any information that could put them on their guard against participating in a fraudulent transaction involved in the sale of such an article to the public. Why the *Pharmaceutical Journal* should be nettled by our exposure is somewhat of a mystery! It goes out of its way to attribute to us a distrust of the drug trade as a whole. It is hardly necessary to remark that the legitimate drug trade has our heartiest support and sympathy as an honourable undertaking characterised by commercial enterprise, high technical education, and sound business methods. By some obliquity of vision the *Pharmaceutical Journal* has confused our attack upon quacks and vendors of fraudulent remedies with an assault upon the members of an honourable calling. It is to be hoped that in future our attitude will be beyond misconstruction, and we welcome the intimation conveyed in the above-quoted article that "the Medical Press is not quite isolated in its aspirations, even though it is without rival." Now that so doughty a trade journal has come into the field, may we look for a general revolt of the retail chemists and druggists against the sale of remedies of a fraudulent nature? Even the want of good taste and good manners may be to a great extent condoned by honesty of purpose and purity of intention.

CURRENT TOPICS.

Diplomas for Nurses.

A very important decision was come to at a recent meeting of the Royal British Nurses' Association, namely, that it is desirable that the Association should hold examinations and grant diplomas in nursing. A scheme embodying twenty-five clauses was carried, with the addition of a further clause, to wit, one empowering the Association to deprive a nurse of her diploma for misconduct or professional incompetence. The Association propose to form centres at convenient spots, such as those possessing a university, medical school, or nurses' training school, and to hold examinations at regular intervals under the management of a committee consisting of a physician, a surgeon, a gynæcologist, and four matrons. This committee is to set the papers, and the examiners appointed are not to examine their own pupils orally. No steps are to be taken by the Association to enquire into or set any standard for preliminary general education, the function aimed at being purely that of a final examining and qualifying body. It is proposed that a fee of two guineas shall be paid by candidates, one half of which should go to the keeping of a register. This move of the Royal British Nurses' Association is a significant one, for it practically amounts to this, that if the scheme is successful and examination and registration by that body becomes the recognised *cachet* of a nurses's capability, the Association will become the governing body of the nursing profession. However well meant, such an ambition is fraught with much danger, unless it can be shown that the Association has the full confidence and support of the medical and nursing professions, and any medical men invited to become examiners will do well to weigh this point seriously. If, however, the effort of the Association stimulates a movement for the organisation of trained nurses into a thoroughly representative organisation, it may accomplish much good.

Sheffield Union Hospital.

A serious state of affairs exists at the Sheffield Union Hospital, and it is one that demands careful attention from the profession. It has become necessary for the resident medical officer and his two assistants to resign their appointments and leave the hospital under circumstances which are notorious to everyone except the Guardians, who either maintain an air of bland astonishment at the conduct of their medical officers, or seek to insinuate that the latter have been advised to do so by the Local Government Board. As a matter of fact, the trouble is the old one which occurs regularly and systematically in every improperly organised hospital, namely, whether the medical superintendent is the responsible administrative officer, or the matron. In this case it seems quite clear that the Guardians have not only not supported the claims of the medical officers, but that they have deliberately placed the management of the hospital, except for the actual treatment of patients, in the hands of the matron. We have frequently commented on similar situations before, and can now only point to this as a further instance of the short-sighted folly of attempting to run any organisation except under a recognised head, and that head in the case of a hospital a medical man. In every department of life, from the British Navy to the common lodging-house there is a single responsible head, and it remains a monument to the fatuity of Sheffield Guardians and a few similar self-important folk that they try to fight the laws on which society is founded. In the case of the present scandal there must in justice be a Local Government Board Inquiry; there are most serious allegations in question, and they must be sifted to the bottom.

Brentford Hospital "Scandal."

The last stage of the Brentford Hospital "scandal" to which reference has frequently been made in these columns was reached on the 11th of this month when a special meeting of the District Council was held to investigate the charges of negligence and want of sympathy made by Councillor G. Pearce against the matron and nursing staff of the Isolation Hospital, in connection with the illness and death of his child in that institution. At the request of the matron a searching inquiry was made and the excited councillor's grave allegations were found to be completely at fault, the medical officer himself being able to give high praise to the matron for her conduct of the case. After a long discussion the Council unanimously passed a resolution exonerating the matron, Miss Ives, and her assistant, Nurse Collins, from all blame, and expressing their confidence in them, Councillor Pearce himself supporting the motion. Then came a further surprise, for Miss Ives having had her character completely cleared promptly handed in her resignation and that of Nurse Collins, on the ground that they could not continue to serve under a council which had given them so little support in their duty. We congratulate both these ladies on the result of the enquiry and on their subsequent action. At the time, now some months ago, we expressed distrust of the accusations on *a priori* grounds, for when a "scandal" is trumpeted about in the daily press it is nearly always the work of some mischievous busybody. The Brentford Council will probably find it difficult to get any efficient substitutes for the two ladies who are leaving them. Like certain other public bodies they seem to have no notion of supporting their own servants when assailed.

An Unexpected Danger.

A correspondent draws the attention of the *Irish Times* to a danger lurking in an unexpected place. On taking his seat in the stalls of a theatre a few nights previously he suddenly felt a sharp pain near the base of the lungs. Investigation showed that a lady occupying the seat behind had pinned her hat to the back of the seat by means of two long hat-pins which protruded some four or five inches. The accident is by no means an uncommon one, and the consequences, though usually trivial, might very well be serious. It is true an ordinary puncture with a clean instrument is not likely to cause other than momentary trouble, but there is no guarantee of the surgical cleanliness of a hat-pin. Such a weapon, piercing some inches into the back, might easily be the medium for the introduction of septic material into the pleural cavity or to the lungs, and very grave conditions might arise as a result. The practice of securing hats in this way should be strictly prohibited by theatre managements. Such prohibition is advisable not merely in the interests of public safety, but may be found to protect the theatre itself, since it is quite probable that the management would be legally liable for damage done to a patron by any accident arising under present conditions.

The Tooth-brush in Schools.

One of the chief recommendations of the Royal Commission on Physical Degeneration was that immediate attention should be paid to the state of the teeth in elementary school children, and no one who knows anything of the subject will be inclined to deny that the dental condition of the rising generation is nearly as bad as it can be. It is, however, one thing to note the disease and another to find the cure, or even the method of prevention. Nearly all those medical inspectors who have investigated children's teeth have recommended the tooth-brush as a preventive, but while as an instrument of elementary cleanliness the tooth-brush is unimpeachable, it is more than questionable whether it has any profound influence on the decay of teeth. Theoretically, of course, it should, but practically we think the matter open to grave question. The children of the better-to-do classes all use their tooth-brush, and all, or nearly all, suffer from early decay, but in their case earlier and more frequent resort to the dentist complicates any fair statistical comparison. The question is whether early decay of the teeth is not due to radical developmental changes in civilised man which the tooth-brush is as powerless to avert as Mrs. Partington's mop was to deal with the waves of the Atlantic. The teeth are intimately connected in their development with that of the jaws, and owing to change of habits and food the jaws are not now of the size and power of those of prehistoric man, nor indeed of the modern savage. To preserve the teeth we must probably breed a good tooth-preserving stock, and, in the absence of such, mere cleaning the teeth will probably do as little to prevent decay as brushing the hair does to prevent premature baldness.

The Anti-Vivisectionists in Ireland.

It is probably news to many of our readers that there is a branch of the National Anti-Vivisectionist Society in Ireland. It does not, we are glad to say, make its presence felt, and it appears to spend most of its time in a condition of hibernation, so that it is on the whole rather harmless. It was perhaps in the hope of rousing it to activity that the Hon. Stephen Coleridge crossed the Channel last week to address the annual meeting. Whether it was the depressing effect of the Channel passage or infection from his somnolent audience that affected Mr. Coleridge, he was not as lively as usual. He seems to have found no fresh "platform facts" of late, and the old ones have been served up too often. He is reported, however, to have said that "vivisectors would justify the placing of two dogs in a cauldron of boiling water to see which dog would get to the other side first." We have never heard this statement before, but still it was hardly satisfying as the *piece de resistance* of the lecture. Mr. Coleridge also patted Sir Thornley Stoker on the back on account of the evidence given by him before the Commission inquiring at present into the question of experiments on animals. All this applause from the enemies of science must be more offensive to Sir Thornley Stoker than the righteous criticism to which he has been subjected from scientific investigators.

The Supply of Anatomical Material in Dublin.

We regret to notice a disposition on the part of the Guardians of the North Dublin Union to place obstacles in the way of supplying bodies to the medical schools for the purpose of anatomical study. At their last meeting the Guardians passed a resolution which may have serious effects in limiting the supply of anatomical material. Up to the present it was open to the Board to give to the schools the bodies of paupers unclaimed by friends, unless the pauper had himself expressed a desire to be buried in the usual way. In future, the question of the disposal of his body is to be brought actively before every inmate of the workhouse, and his wishes are, of course, to be respected. In addition to this, the Guardians forbid, under pain of dismissal, any official to receive any fee in respect of any bodies removed for anatomical examination. These fees, small in amount, were paid by the schools to the medical officer and master for certain certificates necessary by law. It is doubtful whether the prohibition by the Guardians can be made effective, but their expressed wish will, naturally dispose these officials to place difficulties in the way, and the supply of bodies has always been dependent to a great extent on the goodwill of the workhouse officials. The position is one of great gravity, and the efficiency of the Dublin schools of medicine is at stake. We trust that wiser counsels will prevail and that the Guardians may be brought to see that any injury to the schools of medicine is a serious injury to the prestige of the city. Anatomical study is the prime necessity of instruction in the art of medicine, and if Dublin is to maintain its position as an educational centre of importance, vexatious restrictions must not be imposed by the Guardians of the city unions.

Sanatorium Treatment at Moderate Fees.

One of the most satisfactory modern aspects of the tuberculosis question is the undoubted advantage of early sanatorium treatment. Isolation, so far as prevention goes, is clearly desirable in all stages of so infectious a malady, while the cure of the individual entails further measures that as a rule can be carried out efficiently only in a specially organised and equipped institution. Hitherto it has been found impossible to provide sufficient sanatorium accommodation for the poor of our great cities, who die either in their own homes or in poor-law institutions, as only a small proportion can obtain prolonged treatment in consumption hospitals or sanatoria. The well-to-do can obtain first-rate accommodation in abundance, both at home and abroad, and are able to fight the disease under most advantageous conditions. Between the wealthy and the poor, however, comes a large class of consumptives who are able to pay small fees, but for whom there is a lamentable lack of special accommodation. The example of Winsley Sanatorium, therefore, in this respect, deserves attention. The Sanatorium is supported by the counties of Somerset, Gloucester, and Wilts, and last week it was announced by the management that certain beds would be allocated to persons residing within those counties on payment of 35s. a week. They are also willing to receive a limited number of persons not residing within the three counties on a payment of £2 10s. per week. This certainly appears to be a move in the right direction.

PERSONAL.

At Richmond on the 15th inst., the Prince and Princess of Wales opened the Swan Memorial Ophthalmic Ward of the Royal Hospital, generously given by Mrs. Swan.

On the 23rd instant H.R.H. the Prince of Wales opened a handsome set of new buildings for the extension of Glasgow University. The buildings are for the departments of Physiology, Materia Medica, Forensic Medicine, Public Health, and of Natural Philosophy, and have cost between £70,000 and £80,000.

H.R.H. Princess Christian will formally inaugurate the completed portion of the National Sanatorium for workers suffering from Tuberculosis at Beneden, Kent, on Tuesday next. Invitations to luncheon have been issued by Sir Clifton and Lady Robinson in connection therewith.

An unusual honour has been conferred by the King upon Sir Frederick Treves and Sir Francis Laking, in consideration of their great skill and unremitting attention during His Majesty's illness in 1902. The distinction consists in an honourable augmentation to their arms, to these they are henceforth entitled to add one of the lions from the Royal Arms.

Sir Havelock R. Charles, K.C.V.O., M.D., R.U.I., Physician in Ordinary to H.R.H. the Prince of Wales, late Professor of Surgery in Calcutta Medical College, has arrived in England on leave of absence.

It is proposed to endow a Research Professorship at the Liverpool School of Tropical Medicine in memory of Dr. J. E. Dutton, who died at Kasongo, on the Congo, in 1905, from tick fever, contracted during study of the disease. Mr. A. H. Milne, Hon. Sec., Liverpool School of Tropical Medicine, will be glad to receive subscriptions to the fund.

Surgeon-Major R. J. W. Mawhinny, R.A.M.C., from Ferozepore, India, has been appointed to Belfast for duty, and Surgeon-Captain G. Baillie, R.A.M.C., from Quetta, has been posted to the Irish Command at Dublin for duty.

Dr. Thomas Wilson will deliver the Ingleby Lectures of the University of Birmingham on May 9th and 16th on the "Inflammations of the Uterine Appendages."

The Edinburgh University Club will dine at the Criterion Restaurant on Tuesday, May 7th, under the Chairmanship of the Right Hon. Lord Kingsburgh. Members intending to be present should immediately communicate with one of the Hon. Secretaries, Dr. R. Hutchison, 22 Queen Anne Street, or Mr. J. Thomson Walker, F.R.C.S., 30 Queen Anne Street, London, W.

A Clinical Lecture

ON

SOME CASES OF NERVOUS DISEASE. (a)

By WILLIAM CARTER, M.D., B.Sc.; F.R.C.P., LL.B.Lond.,

Senior Physician to the Hospital and Professor of Therapeutics at the University of Liverpool.

Gentlemen,—There are under my care at the present time a number of patients suffering from various forms of nervous disease, all of whom will well repay your careful study. Disease has been deftly and skilfully performing a series of experiments, without any of the disturbing elements often inevitably introduced by the experimental induction of such conditions as you see here, *i.e.*, there has been no trephining, no removal of a portion of the skull or vertebræ, no external violence of any kind to complicate the result. It is our business, first, to interpret, if, and as far as, we can, the cause or causes of the symptoms, which we see manifested; and, secondly, and most important to the patient, to remove those causes and bring about a restoration to health, if, and so far as, we are able.

Let us take the simplest case first, and then proceed to the more complicated.

The patient, a stalwart, powerful fellow, æt. 54, the father of thirteen children of whom twelve are married, was admitted twenty-three days ago suffering from the symptoms which I will describe to those who have not seen him. Now consider them well, and their relations to each other. One of his chief complaints was that he could not eat without biting the right side of the lower lip and cheek, the mucous membrane of which had become severely abraded, owing to this; the right cheek was flaccid, smooth, and expressionless; he had a difficulty in pronouncing some words, especially those containing labials, so that his speech was thick and slow; if he stooped to pick anything off the floor he became giddy and stumbled forward as if about to fall; pain, at first of a severe character, but not increased by pressure, was complained of at the back of the head, and over the back of the neck and right shoulder and down the right arm and leg. On testing his sense of taste, it was found that he could not distinguish salt from sugar on the anterior two-thirds of the tongue, though he recognised quinine at the tip. It was also found that the uvula, which was very long, did not respond to mechanical irritation. For nearly two years he had suffered from what he spoke of as "rheumatics," by which he means pain; and also from occasional slight tinnitus in the right ear. That was ail. The eyes could be closed and opened as in health. The pupils were normal, and vision good. Hearing was practically unaffected—a little less acute in the right than in the left ear. The grasp was very powerful, and equal in each hand; so powerful was it that neither of our dynamometers could register its force, the index being driven instantly in each case to the extremity of the arc. He could stand steadily with the feet close together and the eyes shut. There was no discoverable impairment of sensation, except that of the special sense of taste. I tested the skin of the face in a variety of ways—pinching, pin-prick, &c., and his statement invariably was that he could feel as well on the one side as the other, and as well as he could before the illness commenced.

Now the very simplicity and fewness of the symptoms make the case somewhat puzzling, and its interpretation difficult. If sensation had been impaired on the parts supplied by the fifth nerve—for it was obvious that it was that nerve which was affected and not the seventh; if the eye had been inflamed; if there had been diminished sense of smell, &c., the clinical picture would have been deemed more complete, and the causes of the various lights and shadows entering into its composition more comprehensible. But we must accept facts just as they are presented to us without adding to or subtracting from them for the sake of supposed scientific completeness. Is there any portion of the great fifth nerve which seems to have been specially picked out by the morbid process, whatever that may have been? Certain facts stand out markedly; first, the gustatory or lingual branch of the fifth nerve must have been rendered functionless, or there would not have been the inability to taste salt and sugar or to discriminate between them. Let us trace this nerve and see if there is anything in its course, connections, and distribution which will help us to understand the case. It lies at first beneath the external pterygoid muscle, where it is joined by the chorda tympani, and immediately afterwards beneath the internal pterygoid to which it sends branches; then, pursuing its way, it reaches the side of the tongue over the upper constrictor of the pharynx, where the muscle is attached to the maxillary bone, and, lastly, runs along the side of the tongue to its tip, distributing branches in its course, and ends by joining in a sort of partnership with the hypoglossal nerve. Suppose now that this single branch—the gustatory division of the fifth—could have been deftly picked out by an accomplished experimenter and divided or so squeezed as to be rendered functionless, would not the great majority of this patient's symptoms have followed? I think they would, and that there must in this case have been a singular limitation of the disease-process to this branch, and almost to it alone. But is this possible? Why not? The experimenter often directs his attention to one small nerve and elucidates symptoms by injuring or destroying it; only in such a case as ours, where the nerve lies deeply throughout its whole course, he could not have attained his purpose without complicating the experiment with much injury to more superficial parts, and inducing reflex phenomena which such injury often causes. But are all the symptoms explained on the hypothesis of a disease-experiment on the gustatory nerve near its origin and on it alone? No, I do not think they are. The pain in the occipital region of the skull, and in other parts, as well as the giddiness on stooping, cannot thus be accounted for, and need the involvement of other sensory nerves or their centres. But these had been of long duration, while the other symptoms were comparatively sudden in their onset. What kind of lesion might have attacked this gustatory nerve and the other nerves? Remember the patient's occupation, and the time of the year. He superintended the working of a stationary engine, from the heat of which he was obliged to absent himself, by passing into extreme cold, where perspiration was at once checked. Are such sudden changes liable to be followed by inflammatory or sub-inflammatory deposits? I think that common experience will say that they are. But, if so, is it not curious that a single branch of a single nerve should be picked out for special attention? It may be curious, but even if this branch had alone been attacked it would be by no means unique.

If our vision could be so enlarged as to enable us to see the thickening (and its resulting pressure or irritation indicated by the symptoms) of the gustatory nerve, and possibly other nerves at the posterior part of the head, could we do anything to remove it?

(a) Delivered at the Liverpool Royal Southern Hospital on Feb. 12th, 1907.

There is one remedy which it would be well always to try. Mercury causes the rapid absorption of lowly inflammatory deposits and mercury is too much neglected in modern therapeutics, possibly because it is believed by many to influence only those caused by syphilis. I do not believe for a moment that this man had ever been syphilised, yet we rubbed mercurial ointment into his axillæ, and in a fortnight all his symptoms had disappeared, and he begged to be allowed to go back to his work. He has only consented to stop till to-day in order that you might for yourselves see the results of the treatment employed, if I am correct in judging that the treatment and his restoration to health have any connection with each other.

The next case—and the only other of the five cases of nervous disease that I shall have time to describe to-day—is by no means so simple. Like the last it is that of a powerful healthy-looking man, who also, like the last, is a fireman. But he had better repeat his own story as it was written down from his lips when given to us on January 26th of the present year. It was to the effect that he had never had a day's illness till the evening of the preceding day, January 25th, when he felt pain in the back of the neck, and the back of the left shoulder. He went to bed at midnight, slept well until five the next morning, when, as he says, he awoke with a "creepy" feeling all down his left side, and almost complete loss of power in the right arm and leg. With the aid of two friends, who supported and partly carried him, he was just able to reach the hospital from an adjacent street, when it was found that besides the right motor paralysis, there was great impairment of sensation on the left side extending from the fourth rib in front and the fifth dorsal spine behind, down to and including the feet. Over the whole of this surface from the middle line in front to the dorsal spines behind on the trunk, and over the whole of the left lower limb, he was quite unable to distinguish heat from cold, or the deep prick of a pin from an ordinary touch; the arm, forearm, and hand were not affected. His own idea was that the illness was caused by his sudden passage from an overheated stoke-hole, while he was perspiring, into the intensely cold atmosphere of January 25th, when the temperature was much below freezing. He was quite certain that he had suffered from no accident, and that he had always been well able to do his work up to the morning of admission. On carefully continuing our examination, it became obvious that there was a more extensive disease-process than in the last patient, and, moreover, that it affected only the spinal cord. Thus on the motor side this powerful-looking man, with every effort could only move the index of the dynamometer to 3 with his right hand, while it ran round at once to 43 when grasped with the left hand. The pectorals, rhomboids, and all the muscles of the right upper and forearm were obviously much weakened. When he was carefully got out of bed and made to stand with his feet together and eyes closed, there was but little if any swaying, but the gait on his attempting when supported to move forward, was very unsteady, and on the right side seemed to be spastic. Co-ordination of the muscles of both legs was good, but that of the right hand and arm poor. So much for motor changes. Turning now to the sensory side, there was a curiously mixed distribution. Thus, the merest touch on the right side of the neck and right shoulder caused the intensest pain; while on the left there was the diminished sensation that I have mentioned to you.

The knee and Achilles reflexes were exaggerated. There was plantar left-side extension on irritation, while on the right side there was no reaction. The biceps jerks were active and equal. The circulatory, respiratory, and alimentary systems were normal. Turning now to the cranial nerves, it seemed at first as if one of these at least had been affected, until we learned from him that the defective sight in the left eye had existed unchanged for many years. All when carefully tested, were found to be normal. Sight in the right eye, hearing, smell, and taste were unaffected, his mind and memory were clear, and there had been apparently no passing disturbance of consciousness. What interpretation can be put upon these curiously distributed nervous symptoms? In trying to understand their causation, I think we must bear in mind the comparative, but by no means absolute suddenness of their onset, and the peculiar circumstances immediately preceding this. He had suddenly passed from extreme heat into extreme cold. He went to bed at bedtime, as he believed, quite well, except that there was some pain, though not enough to interfere with the sleep, which for five hours was unbroken and complete. Then he awoke with intense pain and apparently more sudden loss of power over the right half of the body below the neck, and of sensation over a considerable though not quite equal area on the left. I should think that in all probability the parts were affected almost if not simultaneously, but that being in bed and asleep he was not conscious at first either of the loss of power or of sensation. I think we may conclude that the affection was exclusively spinal, *i.e.*, that the cord alone and not the cerebrum was involved in the morbid change. What *was* the change, then, that had in so short a time transformed this powerful, healthy fellow into the weak, shattered creature that you have seen? If you refer to the systematically arranged diseases of the nervous system, the affections which seem to be most nearly reflected in our patient are syringomyelia and hydromyelus; but there are circumstances which compel us to exclude these. Firstly there is the comparative suddenness of onset. Then, again, in both of these cases, the patients were well until they passed suddenly from extreme heat to extreme cold; and the question naturally arises whether the chilling of the surface and its consequent contraction of superficial blood-vessels caused dangerous internal vascular distension, with possibly small hæmorrhages in, or inflammation of, the pia mater. That there was something more than a passing congestion of the membranes of the cord is, I think, pretty certain, as this condition is generally characterised by symptoms from which our patient did not suffer. In it there are fibrillary tremors, and as well oscillatory movements of the fingers, owing to the irregular action of the interossei and lumbricales muscles, and easily seen when the hands are extended and the fingers separated from each other. There are also strange disturbances of sensation—paræsthesiæ—experienced over different portions of the skin and likened by the patient to the hot feeling produced by holding an overheated metallic plate near the surface, &c., &c. Moreover, this condition is often speedily benefited by the use of constrictors of the spinal vessels and counter-irritation on either side of the spine. Thus I have seen the greatest relief afforded by large doses (ʒj) of the liquid extract of ergot, and the application of Brown Sequard's white-hot cautery along either side of the dorsal vertebræ.

But things were different here. If we are correct, as I think we are, in concluding that the spinal cord and its membranes are alone disordered, what affections can explain symptoms so anomalous—almost complete loss of motion on one side and greatly impaired sensation over a large portion of the other? We could more easily have understood them if, the lesion being spinal and not cerebral, the impaired sensation had been on the same side as the motor paralysis, as this association often occurs in the case of lesions, whether experimental or pathological, involving a transverse half. And the pain immediately above the level of the motor paralysis is a common symptom also. But to have *no* diminution of sensation on the side of the motor paralysis, and *great* diminution of it on the opposite side, must be regarded as very unusual.

Then what is the cause of these symptoms, and has it acted on the sensory track or roots on the one side and the motor on the other? I am afraid it would be impossible to decide with certainty. What *is* certain is that the body, when healthy but overheated and with its superficial vessels dilated, was suddenly subjected to intense cold. Was there a dilatation of the vessels of the cord, caused by the constriction of those of the surface of the body? This, I think, is not unlikely. Nor is it unlikely that different areas of the pia mater were affected with different degrees of congestion, nor that where the distension was greatest exudation followed. It was the fear of this which dictated the practice adopted, for I know that such quick and intense beginnings as we had here often have very slow and very painful endings, owing to inflammatory exudations, which subsequently, like cicatricial tissue, contract, press on nerve cells, and cause permanent mischief, unless they are absorbed while in an absorbable condition. Mercury, as ointment, was therefore rubbed in freely morning and night, while the intense pain was allayed by the local application of aconite and belladonna. What has been the result thus far? Sensation has become normal on the left side; he can walk alone fairly well; with the right hand he can send the dynamometric pointer to 13 instead of 3; and the severe pain on the right side of the neck and shoulder is much subdued. We shall therefore persevere for the present, and if necessary later on, call in the aid of electricity, massage, and the hypodermic injection of strychnine, all of which, either together or separately, are of great use where muscular weakness remains for any length of time.

Note.—Electricity and massage were used, as well as the inunction, and the patient left the hospital well in a few weeks.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Arthur Hy. Benson, M.A., M.B. Dub., F.R C.S., Surgeon to the Royal Victoria Eye and Ear Hospital, Ophthalmic Surgeon to the Royal City of Dublin Hospital. Subject: "Glaucoma."*

CLINICAL LECTURES.

In addition to the twelve Clinical Lectures acknowledged as in hand in our issue of the 3rd inst., we have since received, and hereby acknowledge with thanks, the following:—

Bland-Sutton, J., F.R.C.S., Surgeon to the Middlesex Hospital, and Senior Surgeon to the Chelsea Hospital for Women. Subject: "The Value and Fate of Belated Ovaries."

Horrocks, Peter, M.D.Lond., F.R.C.P., Senior Obstetric Physician to, and Lecturer on, Obstetrics and Diseases of Women in Guy's Hospital. Subject: "Disorders of Micturition."

Pringle, Seton, M.B., B.Ch. (Univ., Dub.), F.R.C.S., Surgeon to Mercer's Hospital, Dublin. Subject—"The Treatment of Carcinoma of the Great Intestine."

West, Samuel, M.D.Oxon., F.R.C.P.Lond., Physician to, and Lecturer on, the Principles and Practice of Medicine at St. Bartholomew's Hospital. Subject: "Foods and Feeding in Certain Conditions."

Van Dwellers Stricken with Diphtheria.—An outbreak of diphtheria is reported from Carmarthen district, a family named Jones, who travel about the country in vans, having been affected by the disease. When in camp near Mydrim a child died, and the other children of the family being ill, the authorities removed the Joneses to Carmarthen, their van being taken to an isolated place in the borough for disinfection. The family were also isolated, and their bedding and clothing were either disinfected or burned. The patients, who have almost recovered, will shortly return to their vans.

ORIGINAL PAPERS.

ON THE PRESENT POSITION OF THE TREATMENT OF TUBERCULOSIS BY MARINE CLIMATES. (a)

By WILLIAM EWART, M.D.Cantab., F.R.C.P.
Senior Physician to St. George's Hospital and to the Belgrave Hospital for Children.

Part I.

Mr. President, and Fellows,—The honour conferred upon me by your Council's invitation to open this debate will be best acknowledged by an endeavour to assist you in clearing up the situation, if, as it almost appears from the selection of the title, any doubts should prevail as to where we stand. To that end I may venture to dwell upon principles rather than details, and also to refer briefly to the nature and requirements of the affections to be treated.

Novelty in meteorological facts or in therapeutic methods is hardly to be expected of this address, neither can it provide a complete panorama of the subject. But its freedom from any seaside bias is assured as it has been entrusted to a critic rather than an expert, almost more familiar, after upwards of a score of winter visits to the Alps, with the climate of the altitude than with that of the coast. On that score alone his conclusions would be debatable; and as the practical conclusions are the only essential part of an address, they may be at once briefly enumerated as a basis for the discussion of the suitability of cases for marine treatment:—(1) All cases of *surgical tuberculosis* and scrofula are suitable. (2) All *latent* or *threatened* cases of tuberculosis pulmonalis are suitable. (3) Early cases of *declared tuberculosis* or of "declared phthisis pulmonalis" are debatable, and the responsibility of advice is great, for climatic treatment may turn the scales. They are all fit to try the mountain cure. But failing this not all of them will benefit most at the sea-side; and more equable climates may be indicated. (4) The suitability of cases of *advanced phthisis* can only be decided in relation to the existing prognosis and to personal toleration and preference in regard to climate. Well sheltered marine stations are available, provided the patient's inclination favours them. But in a smaller group, some chances of improvement may still remain which doubtful climatic influences should not be allowed to mar, if on fair trial they should have proved unsatisfactory. (5) The excellent progress maintained at chosen spots along the coast by some cases of *chronic quiescent phthisis* reveals the fact that there are temperaments for which sea-side air is specially favourable, and may be of positive advantage even at the later stages.

The meteorological conditions are a relatively easy study, but their uneven influence upon individuals are as various as the nervous systems which react to them; and these differences are greatly intensified in disease. The sensitiveness of the rheumatic is proverbial. For the majority the approach of rain or of snow is a discomfort, and the fall a relief; but there are exceptions. Again the exhilarating effect of dry frost is not shared by all, but there are those of intense electric susceptibility to whom frost is pain because of its dryness, and who are exhilarated by the change to a damp atmosphere. But in addition to this nervous response to weather, some effect is exerted upon the tissues themselves in health and in disease. These are some of the physiological details which complicate the apparent simplicity of our enquiry.

The mental factor must not be forgotten. For children the sea has boundless charms, and for older minds instruction. We are all as children when gazing upon our terrestial limits with the great unknown beyond; but some invalids might resent the solemn monotony of the scene.

(a) Opening Address to the Debate at the Hastings Meeting of the Balneological and Climatological Society on March 16th, 1907.

The effect upon the nervous system oscillates with the weather and the sky. There may be individual intolerance for the glare, or for the rhythm of the wave. These obvious instances serve to illustrate those more subtle nerve responses which are apt to influence our results.

"*Reaction*"—there is a volume in that significant word which symbolises much of the purpose and of the mode of action of our climatic treatment. The nervous system, and particularly the vasomotor system, appears to furnish the working mechanism of reaction; and its sphere extends widely in two directions that of a stimulation of the general metabolism, and that of the local effects upon skin and mucous membrane, and of the reflected effects upon functions, viscera, and tissues.

Sea Air and Sea Water; and Thalassotherapy.

Sea Water.—The immense ocean, our earth's greater surface, is still, for many purposes, a blank, its wondrous powers and its inexhaustible treasure hidden—except from the vision of the poet. It is true that it has yielded us iodide of potassium and cod liver oil, but other great remedies for our terrestrial ills may yet arise from the deep. For, although two of the branches of "sea treatment"—our sea air and our sea bathing—are as old as the race, the latest branch of "Thalassotherapy," the practical pharmacology of the sea, is still in its infancy.

If there is any special virtue in sea air it must have been derived from sea water. Quinton, of Arcachon, has written a large book on the constitution of the latter, and of its diffused organic contents which, together with its high saline charge, raise it to the value of a serum, and to a strength which has to be diluted more than half (3 parts of distilled water to 2 of sea water) before it is isotonic with our own. In that proportion it has been extensively used, after simple filtration, in moderate sized subcutaneous injections, of which he describes the remarkable results.

As to its other uses, the ancient recipe of sea water as an *internal medicine* has never been much patronised. The chief mode of employment is external. *Sea bathing* is not appropriate for consumptives; but the modified sea bath or *sea-water rubbing* belongs to the daily routine of a marine treatment. It is singular that, whilst inland mineral springs impregnated with the buried residue of former oceans are used for *inhalation* with considerable success, nothing is attempted at our marine stations by way of pulverising the living briny serum for throat-sprays or vapourized inhalations. The method may prove inapplicable in phthisis but it might be tried in other affections.

Sea Air.—The breathing of sea air is apt to get the credit for results not entirely its own. If we bring it to rest, dry it, and warm it, is there still any specific virtue left in it distinctive of the sea? This question cannot be answered off-hand. *Ocean air* is free from microbes and from the coarser particles of which dust is made up; and this purity is reinforced, as it were, by ozone and possibly by radiobes. Are there not, however, some finer and more characteristic constituents analogous to those emanations from soil and vegetation which occupied so large a place in the old etiology of endemics, and still claim consideration in connection with asthma. Asthmatics are acutely conscious of a "closure of the chest" by given atmospheres, and sometimes by that of the sea. We, too, are familiar with the delightful sense of a freer and deeper breath on approaching the coast. Both forms of respiratory reaction suggest an atmospheric cause. And as to their mechanism, this might be a mere intensification of those normal activities with which Watson Williams credits the bronchial muscles in healthy respiration. We *do* know that organic matter is contained in the spray swept up from the wave, and that for every falling crystal which contributes to the saline incrustation of the vegetation, and of every exposed surface on shore, there remains in suspension until oxidised away, a minute quantity of organic matter made up of the lower forms of animal life and of the nutrient basis diffused through the ocean, which must be so fine as to resemble an exhalation, although not comparable to the full-flavoured effluvia arising from the beach. The important question for your discussion is whether sea air is in itself, and apart from added influences, a respiratory stimulant.

The other atmospheric peculiarities are physical rather than chemical and biological. They possess nothing specific, though there is something characteristic in their grouping. Ocean air is always more or less *moist*. But relatively dry air may be blown across narrow seas, as exemplified in our own East winds so discomforting to the soft hydrated nerve endings of a fog-bred race.

The Marine Climates of the Ocean and the Coast.

We must not imagine that the curative virtues of climates are to be judged according to a mere scale of comfort. The open air hardships of pre-historic cave-dwellers may have surpassed in real value some of our climatic refinements. Our ideals must vary with the objects of treatment: and these furnish us with two great climatic types—*the protective and the active, or stimulating*.

There are distant southern shores which offer us close approximations to perfect protection varied with each turn of the French and Italian Riviera and of the African Coast; Mediterranean and Atlantic Islands, too, Corsica, Capri, and Sicily, Madeira, Teneriffe, and the Canaries; besides the more remote West Indian and Californian resorts. In their number are to be found instances of the more bracing type, though sometimes marred by a liability to treacherous winds from mountain or valley. But in general they are unsuitable in summer; and this explains the absence of any systematic national sanatorial enterprise in the Riviera. Our own protecting climates though not so exquisite as those of the cœrulean type, are no less varied, and they are available in summer as well as in winter. Moreover, as we possess a graduated series of bracing stations, we are practically independent as regards marine climates; and this is some compensation for our complete lack of any available altitude.

The Ocean Climate.—An open air life on some small mid-ocean island would give us the unadulterated advantages of a climate which may also be obtained in a modified form and with some drawbacks on any "liner" or in a "floating sanatorium." Sea air from every point of the compass, sea air always, and sea air only, laden with salt and gluey sea stuff, always moist and never freezing, with steady breezes and long dead calms or passing storms, not varying immoderately in temperature from day to night, or even from season to season, clouded at times, but more often glittering with a thousand mirrored suns—radiant, temperate, equable, and moist—this is the marine climate in the fulness of the term. Its characteristic is "equability."

The Sea Coast Climate.—How different the climate of the coast with its ever renewed atmospheric conflicts, and its daily balancing of the temperature-account by breezes from the land and breezes from the sea. Thanks to the latter, sea air is never long absent from shore; but strong winds and long winds may blow from the land, and we then realise that this is not a "climate," but a "mixture" of two climates, a *tertium quid, varium et mutabile semper*. In our latitude it may get frost from the land, but seldom from the sea, which keeps the atmosphere warmer and moister than that inland, relatively temperate, equable and moist, but not in any of these respects equal to the ocean climate, and in none of them constant. Ever astir, the searching damp air keeps things moving, and when it comes from the sea it is "strong air," though it is often only land air possessed of very different qualities; but whether from the sea or from the land, it is apt to rush into fitful disturbing winds: truly a climate of vicissitudes, a school for ever ready reaction: its name is "variability."

In reality each station has a climate of its own which partakes more or less of the marine type according to the extent of its shelter from inland influences and of its open exposure to the sea. Thus sometimes the sea element of the climate may happen to be considerably mitigated. There are indeed those less frankly marine climates in which, far from being eliminated, the land features of configuration, vegetation, and soil are the more essential part.

The variability common to all local climates becomes a drawback or a boon according to the therapeutic requirements. In short, sea-coast climates can seldom boast of being ideal, but they have a wider range of selection and of adaptability to individual cases, if only these opportunities were to be utilized.

Catarrh and the Influence of Wind.

This is the topic of the day; but it is really only a new phase in the old question as to the bracing and the relaxing quality of winds. The chilling influence which they all exercise varies with their strength and temperature. But their varying moisture also largely governs the rates at which heat and electricity are conducted away from the surface; and it accounts for the diverging effects of the south-westerly and of the north-easterly winds which of all others provide us with the most instructive contrast. Dr. Wm. Gordon's laborious investigations have led him to the conclusion that, whatever the effect may be upon the clinical course of the affection, a south-westerly exposure distinctly favours a higher prevalence of pulmonary tuberculosis. The demonstrable fact that moisture is one of the conditions of existence and of activity of the bacillus, tends to support the results of his statistics. An experimental study of the behaviour of the mucous membrane would be a much more difficult matter. But clinically there is no doubt that any sudden transition from cold and dry to mild and muggy weather heralds the onset or the recrudescence of catarrhs. A similar conclusion was pointed out in my article on bronchitis in Clifford Allbutt's System of Medicine on the basis of the Registrar-General's statistics which showed a lower rate of mortality from bronchial affections in the Eastern than in the South-Western Counties. If these conjunctions are not to be regarded as fortuitous they should be capable of some rational explanation in the future. The facts before us read thus—that whilst moisture of air definitely favours bacterial life, it also appears to foster a liability to catarrh, and to lessen the resistance of the organism to the causal factors of the latter. It would thus seem as though wet winds might be conducive not only, as urged by Gordon, to an increased frequency of consumption, but also to an aggravation of its catarrhal tendencies a point of primary importance for our present enquiry in these islands, swept on the one side by the moist Atlantic gales, and on the other by the winds which have yielded their moisture to the intense refrigeration of the polar ice-fields and of the Siberian steppes. Great Britain has lost its evil name as the home of phthisis mainly thanks to the drainage of its damp soil. Perhaps you will bear with some brief remarks upon some of the other factors of catarrh.

The natural history of pulmonary catarrhs would be a simpler one to trace if we possessed evidence that their causation was exclusively microbic. But whilst recognising the probability of an active infective factor, particularly in the more acute febrile colds, which has recently been ably urged by Dr. Prosser White we must still assume that the physical stress of violent oscillations of pressure, of temperature, of moisture, and of electricity, plays no mean part in their etiology. The wonder is that in the integrity of the physiological state we should rise superior to the strain. Between the fulness of health on the one hand, and its pathological disablement on the other, there is no common measure. The mysterious gulf between them cannot be explained, but it is graphically represented by the expression, "collapse of the mechanisms of adaptation," which implies some nervous failure.

A stoker will think nothing of facing, immediately after the fierce heat of the furnace, the coldest wind on deck; but when prostrated by catarrh a slight draught may chill him to the bone and the radiation from an ordinary fire may lead to a profuse coryza. Undue sensitiveness of the surface is with some an innate delicacy; or it may be acquired from injudicious coddling. Little or much of it is invariably induced by the depressing influences of phthisis. Where it exists this individual predisposition to catarrh adds serious responsibility to our climatic selection as even in those free from tubercle it impedes recovery and favours relapse. Such subjects, too, are specially difficult to train up to a toleration for damp or cold air. The contingent which they contribute to the ranks of phthisis is accountable for a large proportion of failures or long delayed recoveries in the "open air" of tnis country or of the Alps. They need an ideal climate of their own; in brief, *the most perfect climate, with a personal correction.* For want of this they are apt to run through the triple series (*a*) of common and influenzal catarrhs, (*b*) of bacillary bronchial catarrhs, and (*c*) of irritative *vomical catarrh* with suppuration generally incurable and disastrous, unless the atmospheric severities be tempered to the irritable membrane.

The intense sensitiveness of the cutaneous surface of many invalids to the slightest impressions conducted by damp air, and the excessive response of the mucous mechanisms are but too genuine; but there is also *the chill "on the mind"* which intensifies the evil. These are poor subjects for our average marine climates in winter; but the initial catarrh, if slight and quite early, may benefit in some warm bracing shelter.

In the absence of any tuberculosis catarrh often finds its natural remedy at the sea; and I believe that the degree of suitability of the particular local climate is reflected in the varying time required. Careful selection will be specially needed in cases where the catarrh is inveterate and its perpetuation fraught with organic consequences, as in bronchiectasis.

The Forms of Tuberculosis.

This is not the place for any pathological discussions, but we may refer to Dr. Nathan Raw's recently published views as they suggest an entirely novel basis for our classification. He believes that the human subject is liable to be attacked by two types of bacillus —the *human* and the *bovine*—and that these two types of infection are not only strictly distinct, but in a sense mutually immunising, so that one infection may be successfully combated by the tuberculin from the other variety. The bacilli of bovine type are supposed to be conveyed by milk through the intestine. Those of human type being inhaled, would thus be almost exclusively responsible for our pulmonary tuberculosis; whilst practically all other forms of tuberculosis would be due to infection of the bovine type.

Whatever eventually may prove to be the fate of this theory, it emphasizes a distinction previously manifest. From our own special standpoint, pulmonary tuberculosis is known to differ much from all other forms in its behaviour under the influence of climate. It is indeed mainly in connection with the pulmonary cases that the value of the marine climate becomes a difficult question. They constitute a separate category, whilst for our climatic purpose all other forms may be grouped together.

Tuberculosis Other than Pulmonary.—We need not dwell long upon this large and varied collection, which includes "surgical" tuberculosis of skin, of bones, of joints and of glands, genito-urinary tuberculosis, abdominal tuberculosis, and the tuberculosis of serous membranes. Happily it may be said of nearly all these that they stand the marine climate wel land tend to benefit from it. The other group cannot be so briefly dismissed.

Pulmonary Tuberculosis and Its Varieties.—The many anatomical and clinical varieties of lung disease really defy classification, as they are the outcome of endlessly various individual proclivities as regards tissue-reaction and function. For our practical therapeutics we shall look only to the broadest features as our guides: but we cannot ignore *predisposition* in its three aspects—the *constitutional* liability to infection, the *localised individual vulnerabilities* of *organs*, and their *functional inadequacies or instabilities*. The individual evolution of tuberculosis pulmonalis is largely determined by the inherited weakness of the lung with tendency to catarrh, combined in the worst cases with a feeble heart. In the large group of lymphatic tuberculosis the defect is not in the lungs; the liability resides in specially vulnerable serous membranes, or in intensely irritable glands. And similar lines of predisposition run through the other varieties.

Happily in many cases of accidental infection the subjects are free from any strong predisposition, and the tendency of the early lesions to a spontaneous cure is evidenced by the frequency with which their vestiges are recognised in the lungs of those who have met with a sudden or violent death in the midst of perfect health, the proportion being 20 per cent. according to the statistics of the Morgue quoted in W. Huggard's excellent Handbook of "Climatic Treatment."

It would be straining the common uses of language to describe as "consumptives" these bearers of "latent" tubercles which may never give occasion either for suspicion or treatment. "Tuberculosis," on the other hand, is an inadequate statement of the multiple miseries which make up the pathological and clinical record of the dying consumptive. As a fact his tubercle was complicated by catarrh, by pneumonia, by necrosis and by sepsis; and in our ministrations none of these could we afford to ignore. There may be then something to be said for the old-fashioned distinction between phthisis and tuberculosis. Only we are now aware that tubercle is the primary event; and we have to reverse Niemeyer's famous dictum and to say: "The worst that can befall the patient infected with tubercle is that he should develop phthisis." The onset of phthisis is the disaster which all our efforts are bent upon warding off; and one of our chief weapons is climate.

The necessity of an adequate definition of cases and stages for purposes of consultation and of treatment is my excuse for the much-abbreviated and incomplete classification, reduced to the ultimate factors of clinical requirement which I now submit.

CLINICAL TYPES OF PULMONARY TUBERCULOSIS.

Mainly Tubercle (*Dry, Grey*).—I. Early, "Local," and often Latent; Healing. III. Late and Declared; "Spreading." IV. Terminal "General" Infective Tuberculosis (Acute or Subacute).

Tubercle with Catarrhal Pneumonia.—II*a*. Acute Caseous Phthisis (mainly pneumonic). II*b*. Common Subacute Phthisis (mainly catarrhal). II*c*. Chronic Excavating Phthisis with catarrh. II*d*. The same without persistent catarrh.

The groups I. and IV. require no comment. Group II., with its sub-groups, shows the varying results arising from different degrees of predisposition to the catarrhal and pneumonic process, *e.g.*, "Galloping Consumption" (II*a*) from its major degree, and "Quiescent Late Phthisis" (II*d*.) from its minor degree. Group III. contrasts with the preceding in the absence of predisposition. It is made up of adults originally of strong constitution, but broken down in their resistance by privation, syphilis, or alcohol.

BY LORD ALLENDALE'S will published last week St. George's Hospital benefits to the extent of £5,000.

DEATH from anthrax was the verdict at Liverpool last week on John McHugh, æt. 37, who had been employed in connection with Glasgow boats at the docks. No hides, however, had been in the cargoes with which he dealt, and the medical man who was called in said that the man must have contracted the disease by inhaling the dust about the docks.

ABDOMINAL COLPOPEXY, PROLAPSUS UTERI (a).

BY PROFESSOR JACOBS, M.D.,
Brussels.

I SHOULD like to detain you for a few minutes in order to consider the radical cure of the severest cases of uterine prolapse—I mean the total hernia of the uterus out of the pelvic cavity, which is ordinarily designated by the name of "complete prolapse of the uterus," accompanied by prolapse of the vagina, or, to be more explicit, the total prolapse of the vagina and the hypertrophic elongation of the vaginal mucosa, which is often covered with excoriations and, sometimes, by very large and deep ulcerations of the external os and of the vagina. All these lesions constitute for a woman one of the most painful infirmities. She is condemned to keep quiet, and to have complete rest; briefly, it is absolute invalidism for the patient. One will readily admit the justification, even the necessity, for such a radical and severe operation as hysterectomy, so much the more as in such cases the different colporraphies, and any other kind of plastic operation, which gives good results in less severe ones, yield only transient and illusory results.

Seeing the numerous recurrences which I had noted, and the continual complaints of patients, I performed for the first time, in 1894, abdominal hysterectomy with the ablation of a large vaginal ring. I finished the operation by the fixation of the vagina to the ligamentary stumps.

This operation I called *abdominal colpopexy*. From 1894 to January, 1907, I performed 77 operations of this kind on patients whose age varied from 43 to 71; I have had one death after operation, which was due to stomachic complications of specific origin. This death has thus no direct relation to the operation. Of the 77 cases I have recorded there have been three cases of slight recurrence, consisting in a certain amount of cystocele due to a small degree of prolapse. Considering these results I am induced to invite your attention to an operation which is indeed very radical, but as a fact not dangerous, and the results of which have been very encouraging during the thirteen years that I have performed it.

Technique of the Operation.—Abdominal section, —the incision reaching to the pubis. The uterus strongly drawn upwards so as to well stretch the vaginal walls is freed on the right and on the left from its ligamentary attachments by the incision of the broad ligaments outside the appendages, and the hæmostasis of the ovarian arteries being secured, the round ligaments are cut, and the section is continued to the supra-vaginal portion of the cervix. Two small forceps are placed on the uterine arteries which are divided. I next divide the utero-sacral ligaments behind, which allows of the immediate withdrawal from the abdomen of the total mass of the uterus and appendages.

By scraping with a small piece of gauze, I detach in front the peritoneum, the bladder and the neighbouring cellular tissue, in this way freeing as far as possible the anterior vaginal wall. Posteriorly I pull back the peritoneum as well as the cellular tissue, so as to strip off the posterior vaginal wall; in the same way the stumps of the broad ligaments close to the cervix, which contain the uterine arteries are drawn back. Here there is slight arterial hæmorrhage, coming from the division of small branches of the uterine artery which run to the cervix, easily controlled by small forceps. The uterus remains attached to the vagina through the insertions of the latter to the cervix. With the finger one can readily locate the vaginal portion of the cervix.

(a) Read before the British Gynæcological Society, April 11th, 1907.

Section of the Vagina.—The section of the vagina must be made so much lower in proportion as the prolapse is pronounced. The section must be such as to remove the hypertrophy of the vaginal mucosa, that is to say, the superabundance of tissue which is always present in old cases of external genital prolapse. Instead of cutting the vaginal canal transversely, I continue the section in a V shape, widely opened towards the top on a level with the vaginal insertion on the cervix, the section being made at first on the anterior, and afterwards on the posterior vaginal wall. Generally this latter section is less important than the first, the posterior prolapse being nearly always less thickened than the anetrior. The two V.V. shaped sections join each other by their branches on the lateral wall of the cervix. The uterus is thus removed with a portion of the vagina, which latter is proportionate to the vaginal prolapse.

I perform then anterior and posterior colporraphies from above, placing my sutures in such a way that the knots disappear within the vagina; that is to say, the stitches cross the vaginal mucosa on one side of the incision, the sub-mucous tissue of the same side, then the submucous tissue of the opposite side and the vaginal mucosa of the other lip of the incision. The stitches are placed from below upwards and tied as soon as they are placed. When the last two stitches are put in, the vagina is shrunk and shortened proportionally to the amount of the excised portion. A few other stitches bring the anterior and posterior walls together and close the vagina.

Lastly, I reconstruct the pelvic floor. An overwhipping suture, beginning from one end of the broad ligament, brings together the two parts of the incised peritoneum, which hide the stumps of the ovarian artery, the round ligament and the uterine artery. A second overwhipping suture is made on the opposite side; these two sutures join each other above the new vaginal vault, which is thus largely covered by the portion of the peritoneum in front. To avoid any possible recurrence of vaginal prolapse, I bind together with two strong silk ligatures, the round ligaments to the vagina; the sutures pass in the following way. They cross the vesical part of the detached peritoneum, the sub-mucous tissues of the anterior wall just about the middle of the new vaginal vault and the posteror wall of the vagina, the utero-sacral ligaments, and finally the peritoneum of the posterior pouch. The round ligament of the corresponding side is drawn in the direction of the vagina, the ends of the silk ligatures, before mentioned, hanging in front and backwards, are then tied forcibly, so as to catch the round ligament in the knot of the suture.

The vagina is thus suspended in the pelvis proportionately to the length of the stump of the round ligament. A similar suture is placed on the opposite side, bringing together the round ligament, the vagina and the utero-sacral ligament of the corresponding side. When the operation is finished, there are in the middle line from the front to the back: the bladder, a vesico-vaginal *cul-de-sac*, the vagina, the posterior peritoneal pouch, the rectum. On the sides: the broad ligaments, which are enforced by the round ligaments stretched between the vagina and the lateral wall of the pelvis.

This operation, which is rather difficult to describe, will as a fact be very easy for any surgeon to perform who is accustomed to abdominal hysterectomies. I think that it does not present as much danger as vaginal hysterectomy, which in these cases of old exterior vaginal prolapsus, is always very difficult. I have never met during the course of the operation the slightest occurrence which could not be foreseen. All the different stages of the operation are as well controlled as in abdominal hysterectomy for fibroma or cancer.

Post-operative Dressing.—Immediately after the operation an antiseptic vaginal dressing is made and renewed every two days till the vagina is healed; when the vaginal sutures of the colporraphies may be removed. The patients are kept for two or three weeks in bed, and subsequently for a few weeks they are advised to refrain from any muscular effort.

The vaginal plastic operations are not absolutely necessary, in more than half of my operated cases I did not have recourse to them, notwithstanding very old and deep tears of the perineum and the vagina. It cannot of course be said that vagino-perineal plastic operations would complete successfully the abdominal operation. The experience I have thus obtained during several years in a total number of 75 patients enables me to say in the most emphatic way that the results of this operation are integrally maintained, notwithstanding prolonged and very tiring labour. For instance: My first patient, a washerwoman, has continued her business for thirteen years, and up to the present there is not the slightest appearance of recurrence. I want especially to point out, that the most delicate point of the operation consists in the avoidance of any lesion of the vaginal mucosa while placing the suspending suture, so as to prevent their slow separation through suppuration.

CLINICAL RECORD.

EXTRA-UTERINE PREGNANCY. (*a*)

Under the care of FREDK. BOWREMAN JESSETT, F.R.C.S.,

Senior Surgeon, Cancer Hospital.

E. S., æt. 30, married, was sent me by Dr. Smyth, Islington, on February 5th, 1907, with a lump in the left side of the abdomen, which she had noticed getting larger during the previous three or four months. Menstruation regular up to five months ago. No children, although married for four years. Has never been pregnant.

History.—Menstruation occurred first week in September, and after that she saw nothing for three months, and began to think herself pregnant, but had no symptoms such as morning sickness or enlargement of the breasts. At this time she changed her residence, and while doing so one morning felt very ill, and went to bed. While in bed she began to lose very copiously, accompanied with pain in the lower part of abdomen. She kept her bed for six weeks,

---

(*a*) Read before the British Gynæcological Society, April 11th, 1907.

losing on and off all the while. At the beginning of this time she had pain in micturition. At the end of the six weeks the bleeding ceased, but she had hardly been able to get out of bed owing to pain. About this time she became conscious that a lump was growing in the left side of the abdomen. This has continued to increase until the time of her admission.

Present State.—On examination of the abdomen, there is a hard irregular mass to be felt in the left iliac fossa, extending above pubes and to the left of umbilicus, somewhat irregular and bossy on surface, moveable from side to side to a limited extent, but this occasions some pain. It is tender on pressure, especially at a point midway between umbilicus and left ant.-sup. spine of ilium. The mass is divided into two portions, a small boss above the pubes, which proved to be the fundus of uterus and tumour. There is no fluctuation, and the mass gives the impression of being solid. It has a smooth rounded edge above; below it dips into the pelvis.

Per Vag.—The uterus has only a limited movement, the fundus is indistinctly felt behind the pubes. In the vaginal fornices the abdominal swelling can be felt by deep pressure. There is no depression or bulging of the fornices.

Operation (February 5th).—The patient being anæsthetised, I opened the abdomen in the middle line between the pubis and umbilicus. The parietal peritoneum was adherent to a rounded dark tumour underneath, which was found to be an extra-uterine gestation sac between the layers of the left broad ligament, with extensive adhesions to the sigmoid flexure, rectum and small intestine. The sac was opened and a dead fœtus (5 or 6 months) and placenta extracted. This was followed by free oozing from the interior of the sac, which was controlled by ligature and pressure. An attempt was now made to separate the sac from its adhesions to parts of the intestine, but it was only found possible to do so to a limited extent owing to bleeding and risk of injury to the bowel. As much, therefore, as could be was ligatured off and removed. The remainder was brought up into the wound and stitched there by a continuous catgut suture passing through the peritoneum, muscle, and the edges of the sac. The sac was now plugged with iodoform gauze, and the rest of the abdominal wound closed in layers.

The patient was rather collapsed on leaving the table, and was given an injection of strychnine.

February 6th.—She rallied well after the operation. General conditions good. The plug was changed on the third day and re-plugged. Ten days after the operation the gauze plug was replaced by a rubber drainage tube, a good deal of discharge escaping. She steadily improved, and the depth of sac rapidly decreased and is now nearly closed, the patient's general condition being excellent.

[I am indebted to my House Surgeon, Mr. Hortop, for these notes.]

OPERATING THEATRES.

GREAT NORTHERN CENTRAL HOSPITAL.

EPITHELIOMA OF THE FLOOR OF THE MOUTH, TONGUE AND FAUCES, WITH EXTENSIVE GLANDULAR INVOLVEMENT—FISTULA, PLASTIC OPERATION TEN MONTHS LATER FOR ITS CLOSURE.—MR. ARTHUR EDMUNDS operated on a man æt. 50, who was suffering from a discharge of saliva from a fistula under the left lower jaw. The patient had presented himself ten months previously with an extensive epithelioma. This involved the left side of the tongue, forming a mass the deeper parts of which extended into the middle line, but the ulceration had only just reached the dorsum of the tongue opposite the front two molar teeth. It extended on the floor of the mouth, and had become adherent to the lower jaws; posteriorly it had involved the root of the anterior pillar of the fauces. Glandular infection was confined to the left side, but was pretty extensive, not only the submaxillary group being affected, but also the glands along the internal jugular. Fortunately the glands were neither very large nor very adherent. The case thus presented a clinical picture, representing about the limit of operative possibility, but the faucial involvement was such that it was thought advisable to attempt an operation. Operation in these instances, Mr. Edmunds said, was not very hopeful, as there are few cases which are permanently cured, but there are many cases which receive considerable benefit from operative interference; it is often possible to completely and permanently extirpate the primary growth, although recurrence takes place in the glands, saving the patient the pain and discomfort of having a sloughing ulcer in his mouth. It was always rather difficult to make up one's mind whether to attack the glands or the growth first, or if both should be removed at one operation. It should be remembered that these patients die of sepsis rather than shock, and no effort should be spared to minimise the severity of the infection. In the present case where the whole of the side of the neck had to be exposed and glands removed almost down to the clavicle, communication between the oral cavity and the cellular tissue of the neck would have been extremely serious, and accordingly operation was performed in two stages. An incision was made with a slight curve upwards parallel to the lower jaw about the level of the hyoid bone extending backwards to the sterno-mastoid muscle, along the anterior border of which the incision was prolonged for about four inches; a flap was thus raised and turned forwards; an extensive dissection of the fat fascia and lymphatic glands of the anterior triangles of the neck was performed and the wound sutured. At the upper part of the incision, where the wound was crossed by the posterior belly of the digastric, an attempt was made to separate the wound of the neck into two portions by stitching this muscle to the deep surface of the overlying skin flap; the advantage of this procedure was well seen in the subsequent stage of the operation, when it became necessary to throw the wound of the neck into communication with the mouth; the whole of the tissues of the neck below the line of the posterior belly of the digastric remained completely shut off, although the upper part above this level became infected. The wound healed normally. A fortnight later an incision was made extending through the middle line of the lower lip to reach the upper limb of the former incision. This was re-opened and a thick flap consisting of the cheek and the tissues over the lower was reflected backwards exposing the bone as far as the coronoid process. Two saw cuts were made through the bone in front and behind the spot to which the growth was adherent, and after division of a few muscular fibres, it was possible to retract the jaw forcibly towards the unaffected side, thus obtaining perfect access to the growth. There was probably, Mr. Edmunds remarked, no incision which gives the surgeon so free an access to growths at the back of the tongue and allows one to keep the respiratory passages so free. In his opinion tracheotomy should never be performed if it can be avoided as this operation prevents the patient coughing properly and prevents the expulsion of any purulent discharge which may have run into the trachea. He was strongly of opinion that the infective pneumonia which was such a dreaded complication of these cases was produced not so much by the insufflation of blood at the operation as by the entry into the bronchi of the purulent discharges from the wound. The growth being thus exposed, it was first seared with a thermo-cautery, to avoid implanting cancer cells in the raw wound. The whole of the tongue with the exception of the tip and the mucous membrane of its right half was freed with scissors and a blunt dissector, practically the whole of the muscles attached to the hyoid bone being removed. An incision was carried into the soft palate and the whole of the anterior pillar of the fauces on the left side turned down. It was now possible with very little dissection to sever the remaining connections of the tumour and to remove it. It was very often possible, he pointed out, to save a considerable portion of the mucous membrane of the tongue, although the surgeon must be careful not to get too close to the ulcer and when possible this should be done as it enables one to stitch up the wound in the floor of the mouth to a much greater extent. In the present case he was able to suture the wound in the soft palate to the mucous membrane at the root of the tongue and to close by catgut sutures the posterior half of the wound in the mouth, and also by sewing together the mucous membrane of the front of the tongue to make a sort of tip for the remains of this organ. In extensive wounds of the mouth it was, he said, very important to unite the mucous membrane as far as possible. This diminishes the granulating surface and consequently the amount of discharge; many of the sutures will, of course give way, but even when this occurs one has often succeeded in converting a wide gap into a narrow cleft. Where possible also some sort of a tip should be made to the tongue in order to prevent adhesion of the front of the stump to the floor of the mouth, a condition which very materially impedes articulation. The wound was sutured and a drainage tube put in at the front angle. The after-history was uneventful and the patient was quite comfortable in about two days. The anterior part of the wound did not heal, and a fistula remained; the object of the present operation was to close this fistula. The whole of the rest of the wound was soundly healed, the patient's general health was extremely good, and there was no sign of recurrence of the growth. He had been back at his work, a carpenter, for several months, and could articulate intelligibly. The patient was anæsthetised, and an incision made around the cutaneous opening of the fistula, a fusiform piece of skin and the epithelium of the fistula were removed. The skin was then dissected up for a short distance, around the wound and its edges united with a few points of silkworm gut. This was successful in closing the fistula, the wound having now completely healed.

TRANSACTIONS OF SOCIETIES.

BRITISH GYNÆCOLOGICAL SOCIETY

Meeting held April 11th, 1907

The President, Mr. W. D. Spanton, in the Chair.

Mr. **Bowreman Jessett** proposed that a vote of condolence be sent to the daughter of their late friend, Dr. Purcell, who was a Foundation Fellow of the Society.

The resolution was carried in silence.

Mr. **Bowreman Jessett** showed the specimen and read notes of a

CASE OF EXTRA-UTERINE PREGNANCY AT THE SIXTH MONTH,

which will be found fully reported on page 450.

The **President** desired to make an apology on behalf of Professor Jacobs, who found it impossible at the last moment, to be present to read the paper he had promised, but had sent a copy of his paper, which Dr. Macnaughton-Jones read, on

THE RADICAL CURE OF PROLAPSUS UTERI,

which will be found fully reported on page 449.

The **President** said the subject was interesting, and although it opened up one particular operation for the relief and cure of prolapse, he took it that on the present occasion it would be agreeable to the Fellows to broaden the discussion, so as to embrace the general aspects of the subject.

Sir **William Smyly** said he was surprised at the successful results which Professor Jacobs had obtained from the operation. He would not have imagined that removal of the uterus and part of the vagina, even with colporrhaphy, in extreme cases of prolapse, would have resulted in such a large proportion of cures—*i.e.*, 70 cases out of 75. The operative treatment of very bad cases of prolapse was one of the most unsatisfactory in gynæcology, in his opinion. In cases where the pelvic diaphragm was completely torn through and destroyed, and where there was complete procidentia of the uterus through the vagina, any operation which gave such good results should be hailed with the greatest pleasure by gynæcologists. As to the general subject of prolapse, he believed that the vast majority of cases of prolapse could be divided, as Hegar had said, into two groups—those which depended upon relaxation of the peritoneum—vaginal enteroptosis, and those which depended on injury to the pelvic floor, especially to the pelvic diaphragm. Those were two absolutely different classes, and required different treatment. The paper which had been read would apply to both those forms, and would help gynæcologists in the treatment of them. But the second form, that in which the prolapse depended upon injury to the pelvic floor, he had no doubt was in the majority of cases the results of bad midwifery—that is to say, the result of the improper use of forceps. He felt certain that women who had their pelvic floors torn through with the forceps, if they had been allowed to deliver themselves, would have escaped procidentia. The next important point in the treatment of prolapse, he thought, was that the cases must be operated upon early. The women who had prolapse were generally old, and were shy of operations, and it was common for them to ask whether something else short of operation could not be done, such as treatment by means of a pessary. His usual reply to such patients was that he could put off the operation for a few years, but it would be increased in risk, and the ultimate result would be less successful than if the operation were done now. He thought it was most important that in the first place the physician should make a diagnosis as to the exact form of prolapse. But in the case of any woman who had a tendency to prolapse, to retroversion with descent and injury to the pelvic floor, his opinion was that the sooner she was operated upon the better the results would be.

Mr. **Christopher Martin** said his practice was to treat all cases with Sir James Simpson's pessary, and he did not operate on cases unless he found that the prolapse would not keep up with this pessary. In the majority of cases—perhaps in 9 out of 10—that was all that was necessary. There were some cases in which it would not keep back the prolapse, but then he was sure no Hodge or ring pessary would do so either. In such cases ventro-fixation combined with an extensive colpo-perineorrhaphy was sufficient. He believed that most cases of bad prolapse should be looked upon as similar to an ordinary hernia, either umbilical or inguinal, and in doing a radical cure of hernia the essential part of the operation was to reconstruct the fascial structures. Therefore any extensive cutting away of the mucous membrane in the vagina only was futile. The uterus was not suspended by the mucous membrane of the vagina, nor by the peritoneum. The essential thing in an extensive operation for prolapse was to restore, as far as possible, the pelvic fascia, and if it were possible to reconstruct the pelvic fascia and bring back the condition to that which obtained in the virgin, the operation would be a perfect one. A year or two ago he read a paper before the Society on radical cure for prolapse, and the operation recommended was removal of the uterus and of the vaginal mucous membrane, and—what was the essential part of the operation—the bringing together of the pelvic fascia from side to side. In that way the diaphragm was made of pelvic fascia between the rectum behind and below, and the bladder in front and above. In that way the fault caused by the vagina was done away with, and one segment of the pelvic floor did not slide over the other, but a hammock of membrane passed across and supported the viscera. It was a severe operation, but if it did not kill the patient it cured her. He had operated upon four cases in that way, and they had all recovered. Still, they all had a serious convalescence, and at one stage it was doubtful in each case whether they would get well He feared there would be cases in which this operation described would fail. Certainly he had seen extensive ventro-fixation and colpo-perineorrhaphy fail. He was surprised that there had been such a large proportion of cases of cure.

Dr. **Macnaughton-Jones** said that there could be no question that this operation offered many advantages in the treatment of exceptionally severe cases of prolapse. An important point was that in enclosing in all the structures forming the vault of the vagina after the hysterectomy, the round ligaments, and the utero-sacral ligaments were included. As had been said, the suspension of the vagina was in proportion to the length of the stumps of the round ligament. As an abdominal operation, it appeared to be as complete and radical as could be desired. He thought that in operative gynæcological work, if an operative procedure entailed greater risks to life than those involved in the condition which it was proposed to remove, it was rarely justifiable; and, no matter how successful an operator might be, this in itself might not justify the step. This operation no one could deny was a serious one. He quite agreed that the important point in treating these cases of prolapse of the uterus was early rectification of the original anatomical defects. Relaxation of the vaginal outlet, retroversion of the uterus, with descent of the vagina, associated with commencing cystocœle or rectocœle, were usually dealt with successfully by free colpoperineorrhaphy with colporrhaphy, and, if necessary, suspension of the uterus. He had gradually grown to look on all pessaries as necessary evils, and avoided their employment whenever it was possible. They frequently did more harm than good, often by reducing the tone of the vaginal wall, their after-effects tending to increase rather than to cure the evil they were meant to rectify. This necessarily applied more particularly to pessaries of a large size. The question was also raised in Professor Jacob's paper as to the relative advantages of abdominal and vaginal coeliotomy in these cases. To illustrate his meaning, Dr. Macnaughton-Jones showed the uterus of a patient, now aged 84, from whom nine years ago he removed it for a prolapse of twenty-five years duration, and it could be seen that the bladder and rectum were adherent to the greater part of the uterine surfaces, all three being contained in the procident sac. A large portion of the vaginal canal was removed at the same time, and the whole structures were united to form a new vault. The second uterus shown, removed also by the vaginal route, was even a worse case than this. In the sac was a myomatous uterus with mucoid degeneration of its canal. The sac contained the bladder, adherent to three-fourths of the anterior surface of the uterus, and the rectum to its posterior. The same operation was performed, and the patient had no trouble subsequently. In both cases there were severe ulcerations on the exterior of the mass. This, he thought, proved that, though he did not doubt that the abdominal route was the best, extreme prolapse could be successfully dealt with by the vagina. Dr. Macnaughton-Jones showed four models of sections of the pelvic viscera prepared at the *Medizinisch Warenhaus*, Berlin. The sections were made by Professor Freund, of Berlin, and V. Rosthorn, of Heidelberg. They showed beautifully the various organs, with the muscles and fascia of the pelvis and its walls, by frontal, sagittal and horizontal sections.

Mr. **Bowreman Jessett** said the first point of interest in connection with the paper was the large number of cases in which the operation had been performed. The cases were those of complete prolapse, in which the uterus came through the vulva. In these severe cases the only means of cure was to remove the uterus, and he thought that exactly the same result would be attained by removing it by the vagina as by an abdominal operation. He agreed that after removal of the uterus it was necessary to stitch across the pelvic fascia and include the round ligaments in the first line of sutures, and then do an extensive anterior and posterior colporrhaphy. In that way considerable shrinking of the vagina was produced, with a sound vault. His experience had extended to about 23 cases. He thought the simpler the operation the better, and he could not see the object of opening the abdomen and pushing the uterus, which was protruding through the thighs, up through the abdominal wall before removing it.

Miss **Garrett Anderson** said the extremely bad cases of prolapse which had been described were not very common The operation which had been carried out at the New Hospital for Women during the last few years was intra-peritoneal shortening of the round ligaments, which she believed was a successful procedure, though it was necessary for a longer time to elapse before a proper test of the value of the operation could be made. For the bad cases vaginal hysterectomy had been done, combined with closure by a plastic procedure.

Dr. **Ethel Vaughan** said in those cases of complete prolapse of the uterus one should make a distinction between those which occurred in younger women and those taking place after the climacteric. She did not say that hysterectomy was justifiable for a procidentia of the uterus in young women, but after the climacteric the uterus had done its special work and become a more or less useless appendage, so that the reasons against its removal were much less valid than in a younger patient, and in such a case, if it was convenient to remove the uterus, she thought there should be no hesitation in doing so. Just before Christmas she had such a case, where the vagina was enormously hypertrophied and elongated, and after removing about three inches of it, as well as the uterus, she closed the upper end of the vagina with catgut and suspended it to the peritoneum and subperitoneal fat above the bladder, as one would do in suspension of the uterus. The patient had done very well, and had been completely relieved of her trouble. She united the pelvic peritoneum before tying the silkworm gut stitches which suspended the vagina to the abdominal wall. She thought that in younger women an operation which was very useful was a posterior suspension of the uterus done by Kelly's method. Among the causes of procidentia which should be mentioned, as well as lesions in the floor and those due to intra-abdominal tension, were those due to dragging down of the uterus, either by a fibroid or from a bulky elongated cervix, because in the last class of cases supra-vaginal amputation of the cervix very often completely relieved the patient. With regard to palliative measures, she wished to mention a pessary which had been designed by Miss Aldrich Blake, and which she thought a great improvement on the cup and stem pessary. It consited of a vulcanite ring on a slightly curved stem, so that all pressure on the cervix itself was avoided.

Mr. **Furneaux Jordan** said he thought the worst cases of prolapse occurred mostly after the climacteric. He believe all the cases mentioned in the paper were between the ages of 41 and 75, so that there were very few of the patients under the climacteric age. He agreed that the plastic operation, with the addition of ventro-fixation or suspension, was quite enough. But cases did occur which defied all methods of suspension or any plastic operation. Although he saw large numbers of out-patients every week, he had seen only two cases in which he had found it necessary to remove the uterus, and in those two he performed vaginal hysterectomy. It struck him at the time that there was no certainty of being able to support the vaginal vault, and in those extreme cases the operation described in the paper would probably be successful. It was stated in the paper that it was not a difficult operation, but it seemed from the description as if it were a serious procedure, and was likely to be rarely justifiable. Still, it was clearly justifiable in cases of cancer, and in the last six months he had removed the uterus and the broad ligaments and the appendages and the vault of the vagina in four cases of cancer of the cervix. That was a tedious and serious operation, though it was not very difficult to carry out, and it would be far easier to do in a case of prolapse than in one of cancer of the cervix. Each time he had performed that operation he had fastened the stump of the round ligament and the broad ligament to the posterior vaginal wall below the fixation, and he could bear witness to the fact that in those cases which had been examined afterwards the vagina seemed taut or strung up to some extent by the attachment to the abdominal wall by the round ligament. He cordially agreed with the view that in extreme cases the operation would be necessary. He did not think it was an operation which would be often justifiable.

Dr. C. H. F. ROUTH said in his early days he remembered two cases which were very remarkable. In those days, when the uterus was prolapsed and projecting completely out of the vagina, the cause was some violent effort made at delivery in the case of a very large child, and the treatment of that day was remarkable—namely, to procure a very large ball, almost as large as the internal diameter of a cocoanut, and push that up the vagina as far as it would go. On different dates he was called to see two ladies who each had one of those balls inside the vagina. That kept the uterus up so that it never came down afterwards. But of course such a body was very uncomfortable. Had he not seen what was described he would have regarded it as an invention on the part of somebody who wanted to talk of matters of which he knew nothing. In both those cases he was obliged to use forceps, with the patient under chloroform, and it required much pulling to get it away. The odour from it was very repulsive. Yet some patients had such a ball in the abdomen for five years. After removal, astringent injections were used, and the patients kept quiet, and sometimes water which was almost boiling was employed, and also hot irons. In the end both patients got perfectly well, the vagina contracted, and no further untoward result ensued. Of course he did not recommend that procedure, but he thought it worth while to remind Fellows that such procedures were once practised, and yet, as far as he knew, perfect cures resulted.

Mr. MANSELL MOULLIN said he had been rather astonished to hear remarks from different speakers as to the scarcity of those cases of prolapse. Looking back on his experience of many years he could remember hundreds of them, and he did not feel at all astonished at the numbers mentioned in the paper. Every effort was made in the out-patient departments to relieve patients by means of pessaries, etc., and the cases were regarded as more or less hopeless for operation. He agreed that any palliative measures for the relief of prolapse was absolutely futile. In some of the cases in which the condition was in the early stage, colporrhaphy might be of some use, but for a bad case such a procedure he regarded as absolutely useless. He was certain that the union of the fascia was the one point which offered the only scientific and reasonable hope for the relief of cases of prolapse.

Dr. HEYWOOD SMITH said that patience was a virtue which operators sometimes lacked, as sufficient time was not allowed to see what a prolonged course of treatment might do. If patients suffering from prolapse were placed on their backs, or even tilted up on a bed which enabled that to be done, with some weeks' rest, it would be possible, with the application of some proper pessary, to keep the uterus in fair position. In young patients a rest and astringent injections toned up the vaginal wall, and a pessary which was large enough rested on the side of the walls and the bony part of the pelvis, and so kept up the uterus. Professor Simpson's pessary was perfect.

Dr. NEATBY said when he began operating he tried colporrhaphy and perineorrhaphy combined. Then he tried ventral suspension. But what he found most useful was that those should be done together, as by suspension alone the heavy redundant vaginal walls were sure to pull down the uterus and stretch the adhesions; while with colporrhaphy alone the heavy uterus was sure to force down the vagina. Some patients would bear the two procedures at the same sitting.

Dr. S. J. AARONS said he thought prolapse was practically a hernia, and there was no real way of reducing such a hernia radically except by operation. Some form of pessary was certainly an advantage. The one which Dr. Ethel Vaughan had referred to had been in use in Soho Hospital for many years, or one very similar, consisting of a ring with a stem and a sacral curve in it, which had a strap passing over the nates. In the out-patient department we learnt to try and cure cases without sending them into the hospital. Many cases were treated and made quite comfortable with pessaries. For some the ring and stem were used, and in others the pessary with the shelf, while others had the simple ring; the cases were also seen where there had been ventral suspension with fixation, and had returned with a large cystocele and rectocele. Therefore, the results of those operations required watching for many years before it was possible to say a cure had been effected. In those cases of prolapse where there were cystocœle and rectocœle he thought a pessary would do as much good for the patient as any operation.

Dr. C. H. BENNETT said he had had some experience in the matters under discussion. On two particular occasions a perfect cure was brought about by using pessaries, and at the same time giving the patient cold Sitz baths half an hour at a time three times a day. Those patients got perfectly well and remained so. With regard to the use of forceps, his experience was that forceps were employed for the convenience of the medical man, and not for the benefit of the patient in many cases. He said deliberately that the medical attendant was in many instances directly answerable for prolapse of the uterus when it occurred, and for the trouble which many patients suffered in confinement. Though he had been in practice for a good many years, he had never lost a case of midwifery in his life. He attributed that largely to the patience he exercised in allowing Nature to do her work without hurrying it.

Dr. H. HODGSON said he hoped, when the discussion opened, that something would be said about the cause of prolapse of the uterus. So far all that had been said on the matter was what Fellows had heard many times before, namely, that prolapse was due to an insufficiency of the ligaments and to their giving way. Consideration of the anatomy of the parts would show that it was nothing to do with the ligaments; it would be clear that the ligaments were stretched and injured by he prolapse, and not that the prolapse came as a consequence of the ligamentous failure. It would be seen that the ends of the ligaments which were attached to the uterus formed a band round the uterus where the internal os was. Then the prolapse commenced, with elongation of the cervix, which in itself was fairly clear evidence that there was pressure on the fundus, driving down the conical uterus through the resisting ring, that ring being formed by the ends of the ligaments. Even if those ligaments were made of steel he thought prolapse would still occur. The cause appeared to be some alteration of intra-abdominal pressure plus a flaccid condition of the parts, or some growth. Normally, the abdominal pressure should be neutral, but many things would cause it to be plus, and it was one of those causes which first started the downward progress of the uterus. The uterus formed a cone or wedge, and only a little movement sufficed to drive it through the ring.

The PRESIDENT said it was quite clear that in speaking of prolapse of the uterus many different conditions were discussed. Pure prolapse was one thing, but it assumed so many different forms, and arose from so many different causes, that to deal with it in debate from one point alone was misleading. It was necessary to take the out-patient department view of it, and also the in-patient department view. The out-patient department gentleman had stated that evening, and he thought very properly, that many cases were amenable to treatment by pessaries—at any rate to the extent of permitting the patient who applied for relief, to go about her duties again. That was the important point which must be considered in the matter. It was not every case of prolapse which demanded severe and grave operations, and such operations should only be undertaken when the patient expressed a strong wish to have the operation done. If an operation of a grave and complete character was to be carried out, that of Professor Jacobs commended itself as the most effective which could be devised. But, short of that, he was inclined to share the views of those who thought that in the majority of cases it was clear that in young patients if the cervix were removed it was often sufficient, because the vagina contracted up and the prolapse was cured. Then there was a class of case which occurred in elderly women, where the vagina was very patulous, and had lost the whole of its tone, for which nothing short of an extensive operation would be effective. The operation which had been described that evening must be attempted in such a case, or else a large vaginal operation. His own experience had been mainly in treating through the vagina, and, having had a large number of such cases, he was able to say that the results on the whole had been satisfactory. The old operations, such as Emmet's, were altogether failures, and always gave way sooner or later. But if one excised a large portion of the vaginal wall, taking away the whole of the cervix, and restored the perineal body, in many cases the woman would be able to go about with perfect comfort, and she would probably be able to resume her usual active work. It had been very properly stated that a patient should not have an operation performed which subjected her to greater risks than did the condition for which the operation was to be done. He noticed that no mention had been made that evening of the Alexander operation. Some time ago Dr. Alexander read a very interesting paper before the Society, and many people appeared to carry it out, and still found it effective. But he feared that many surgeons did not find it as effective a procedure as some of their Fellows did, or as the author himself did. The discussion had been a most interesting one, and the thanks of the Society would be sent to Professor Jacobs and also to Dr. Macnaughton-Jones for having made the translation and brought the matter before the Society.

The meeting then terminated.

ROYAL ACADEMY OF MEDICINE IN IRELAND

Section of Medicine.

Meeting held Friday, April 5th, 1907.

The President, J. M. Redmond, in the Chair.

UNUSUAL NERVOUS SYMPTOMS.

Dr. Dempsey exhibited a case showing unusual nervous symptoms, which he regarded as the result of multiple spinal sclerosis. The case was discussed by Dr. Craig.

ANEURYSM OF THE THORACIC AORTA.

Dr. **Winter** showed a man suffering from the above. The man suffered from loss of voice, owing to paralysis of his right vocal cord. There were no physical signs, other than a limited area of dulness on percussion and some difficulty in deglutition. On examination with X-rays a definite pulsating tumour could be seen on the left of the sternum.

PSEUDO-RENAL COLIC.

Dr. **Parsons** read a paper on the above, which was an account of a case which had long defied diagnosis, but had ultimately been correctly diagnosed as an aortic aneurysm. The specimen was exhibited.

ADDISON'S DISEASE.

Dr. **Dempsey** read an account of a case of Addison's disease of unusually short duration.

CEREBRO-SPINAL FEVER OCCCURRING IN A CHILD THE SUBJECT OF LYMPHATISM.

Dr. **George Peacocke** read a paper on the above subject in a girl, æt. five years, which ended fatally eleven hours after the onset of symptoms. The chief symptom was repeated attacks of convulsions. There was only slight retraction of the head. Kernig's sign was absent. There were several purpuric spots of irregular size present on the legs and arms. The *post-mortem* revealed the presence of lymphatism, enlarged and bulky thymus, enlarged mesenteric glands, hypertrophied Peyer's patches and solitary follicles, prominence of the Malpighian corpuscles on section of the spleen. Cerebro-spinal fluid removed by lumbar puncture, shown after death, was turbid, the turbidity being due to leucocytes. Weichselbaum's meningococcus was found.

Dr. **Harvey** explained the microscopic slides.

Dr. **Kirkpatrick** asked if a diagnosis of the condition of lymphatism had been made before death, and if there was any way by which it could be recognised. The condition had been found in a number of cases in which sudden death had occurred during the administration of anæsthethics for operations, and the diagnosis of lymphatism before death was a matter of practical importance.

Professor **White** thought it possible that the condition of lymphatism had a good deal to say to the question of infection. Most of the cases that died of cerebro-spinal meningitis had had trouble with adenoids, and a good deal of lymphoid tissue at the back of the nose, and it was possible that they became infected in that way. The organisms existed in some healthy people. At the back of the nose there were many kinds of diplococci, many difficult to distinguish from the organism in cerebro-spinal fever. The only case in which he saw a *post-mortem* in the present outbreak had the condition which Dr. Peacocke called lymphatism.

Dr. **Peacocke**, in reply, said the idea of lymphatism did not occur to him during the patient's life. The symptoms before death were, unfortunately, practically nil, and the only physical sign likely to be detected would be the presence of a very large thymus showing dulness.

LARYNGOLOGICAL SOCIETY OF LONDON.

Meeting held April 5th, 1907.

The President, Dr. J. B. Ball, in the Chair.

Dr. St. Clair Thomson exhibited a man, æt. 29, who had been shown at the previous meeting on account of a "malignant endo-laryngeal growth." Since then an operation had been performed for its removal, and a section of the growth was exhibited. As some of the members were unable to satisfy themselves that the growth was of a malignant nature, it was decided to refer it to the Morbid Growths Committee for a further opinion. The interest of the case rested in the early age of the patient.

Dr. **St. Clair Thomson** also exhibited a woman æt. 50, with prolapse of the ventricle of Morgagni. This patient had also been exhibited at a previous meeting, and since then the prolapse had been removed. A microscopic section presented mainly œdematous tissue.

Dr. **H. J. Davis** exhibited, a boy, æt. 12, who, according to his mother's statement, had never spoken. The boy was unable to protrude his tongue. He was very intelligent, and he heard and understood perfectly. He could hum songs in tune, but could not speak a word (aphemia). At the age of three, it was stated, he had right hemiplegia. Opinions were invited as to suitable treatment.

Dr. **James Donelan** cited a similar case in which improvement followed education in a deaf and dumb institution.

Dr. **Dundas Grant** considered that there was much mechanical defect through weakness in the muscles of articulation.

Dr. **Watson Williams** considered that there was a lesion in the neighbourhood of Broca's convolution, and that there might have been an injury at birth. He agreed with Dr. Donelan's suggestion.

Dr. **de Havilland Hall** considered the case to be one which should be trained, and pointed out that the mother should be informed that the treatment would be a matter of years.

Mr. C. A. **Parker** also considered that the patient would do well under training, unless the disuse of his tongue had rendered articulation impossible.

Dr. **Davis** in reply considered that the boy could not speak owing to the paralysis of the tongue, and on that account he would not derive much benefit from being trained.

Dr. **Donelan** exhibited a patient with destruction of the columella of the nose occasioned either by syphilis or by lupus. Various suggestions were made for overcoming the resulting defect, opinions being divided between a plastic operation and the use of a mechanical appliance. In view of there being some evidence of active disease, Dr. Donelan decided to observe the case a little longer before doing anything of a surgical nature.

Dr. **Dundas Grant** exhibited a case of

PHARYNGO-KERATOSIS (MYCOSIS)

improving under the application of salicylic acid in sulpho-ricinate of soda. The patient had been under this treatment for twelve months. When first seen by Dr. Grant various applications were made, first a saturated solution of salicylic acid in alcohol to the spots on the right tonsil, the galvano-cautery to the left one, then pure formalin to the left one and a 10 per cent. solution of sulpho-ricinate of soda to the right. Next a one per cent. solution of formalin in glycerine was applied for a month, at the end of which time comparatively no change had taken place. She then commenced a daily application of a 10 per cent. solution of salicylic acid in sulpho-ricinate of soda, first to the right tonsil, and then to both. The patient complained at times of the application producing a dry feeling in the throat at night, but eventually scarcely a vestige of the disease remained.

The **President** said that he had tried salicylic acid for mycosis, but that he did not have much faith in the treatment.

Dr. **de Havilland Hall** commented on the way that keratosis, like warts elsewhere, would sometimes clear up in an astonishing way.

Sir **Felix Semon** enquired why keratosis should be treated locally at all, inasmuch as it always got well of itself. He considered that there was no real remedy for the condition, constant applications to the throat rendered the patient needlessly nervous, and greater importance was attributed to the malady than it deserved. Moreover, the man who treated such a trifling condition for a long time exposed himself to recrimination.

Sir **Felix Semon** hoped the profession would recognise that keratosis occurred when the patient was run down, and that it would disappear under a change of air and tonic treatment, and that no local treatment was necessary.

Dr. **Fitzgerald Powell** had found that cases generally got well after the application of a cautery.

Mr. **Herbert Tilley** also spoke of spontaneous disappearance of the condition without local treatment.

Dr. **Dundas Grant**, in reply, expressed himself in agreement with Sir Felix Semon. He had put before the patient the fact that the appearance of the throat was of no significance. and thought the discomfort that the patient had gone through in using the remedy was out of proportion to the result. He would not recommend the treatment in every case of the kind.

Dr. **Jobson Horne** exhibited a macroscopic specimen of lympho-sarcoma of the mediastinum. The growth had caused extensive obstruction, almost obliteration, of the œsophagus without any breach of the mucous membrane. The larynx presented œdema localised to the right arytenoid region; immediately below the œdema in the fold passing down between the cartilages of Santorini and Wrisberg was a small ulcer. The points of interest were the unusual extent of the œsophageal obstruction, and also whether the localised œdema of the larynx was occasioned by local infection, or was secondary to obstruction caused by the mediastinal growth.

THE THERAPEUTICAL SOCIETY.

Meeting held in the Apothecaries' Hall on April 16th, 1907.

Dr. J. E. **Burton Brown**, President, in the Chair.

Dr. **George Oliver** read some notes on the

CONTROL OF A SUPERNORMAL ARTERIAL PRESSURE.

He gave the leading results of his clinical observations on the management of a persistent rise in the arterial pressure by diet, baths, electricity, and remedies. He pointed out the value of a non-stimulating diet, and especially of a lacto-vegetarian and salt-free diet in the high pressure cases; a minimum proportion of calcium salts in drinking water; warm massage douchings; saline and carbonic acid baths; D'arsonvalization and the electric light and ozone baths; warm equable climates (Jamaica, India, and Egypt); evacuant treatment; asepsis of the bowels; and apressor remedies. He indicated some practical suggestions furnished by physiology in the selection of apressor remedies for less or more continuous use, and stated his further favourable experience of the benzine derivatives at the same time, showing that our control over persistent increments of arterial pressure is limited to the cases in which the pressure rise is moderate and the vaso-motor play of the peripheral arteries is not seriously impaired.

Sir **Lauder Brunton** considered Dr. Oliver's paper very valuable. He thought that in cases of very high tension absolute rest in bed with quiet of body and mind was indispensable. With perfect rest, vegetarian diet, and the steady use of nitrites even cases of exceedingly high tension might be successfully treated. A salt-free diet might be useful in cases of very high tension, but it could not be continued for a length of time as it is so irksome. Salt might be to a considerable extent replaced by sugar in the dietary. The modern treatment of high tension by nitrites and nitrates had been recommended by Lord Bacon in the time of Elizabeth, as the two remedies he recommended for prolongation of life were nitre and blood letting. The nitre he employed probably contained a quantity of nitrates, and blood letting was a remedy which had fallen too much into disuse, and in cases of high tension might be employed again with advantage. He showed Von Basch's instrument as modified by Potain for estimating blood pressure, and also a combination of this instrument with Riva Rocci's armlet.

Dr. **Herbert French** reminded the Society that cases of very high blood pressure occurred even amongst those who were at the same time vegetarians, non-smokers, and life-long abstainers.

In his reply Dr. **Oliver** agreed that rest in bed would diminish the high blood pressure even in the worst cases, but this was owing to a diminished call upon the cardiac end of the circulation. In those who were obliged to work, the ventricle factor could not be diminished, and such cases seldom reacted to apressor drugs so long as they remained up and about. He thoroughly approved of the revival of venesection for such cases.

Dr. Pallow, of Maesteg, died suddenly last week. He became unconscious, and Dr. Sheen, Cardiff, was called in for consultation. The patient, however, failed to recover, death being due to meningitis.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.

MEETING HELD WEDNESDAY, APRIL 10TH, 1907.

DR. FREDERIC BAGSHAWE (St. Leonards-on-Sea) in the Chair.

THE adjourned discussion on

"THE PRESENT POSITION OF THE TREATMENT OF TUBERCULOSIS IN MARINE CLIMATES,"

which was introduced by Dr. William Ewart at Hastings on March 16th, was resumed by Dr. Alfred Street (Westgate-on-Sea). He said that the weight of evidence was on the side of those who contend that pulmonary catarrh is essentially microbic in origin, and that it always owns a factor other than mere cold. The humidity of marine climates was usually a tolerable humidity, for humidity must always be considered in relation with temperature, the really important point being the amount of moisture which can still be absorbed before saturation is reached. The climate of the north coast of the Isle of Thanet has long been recognised for its favourable influence in cases of tuberculosis, especially those amenable to surgery, but its precise factors are not yet discovered. Cases of locally originated tuberculosis are rare there. Hæmoptysis may be relatively more frequent at the seaside than inland, and there is need for abundant open air shelter. As maintained by the opener of the discussion, the more extensive and more systematic use of our marine climates is strongly indicated.

Dr. SOLLY (Harrogate) alluded to the beneficial influence of variety of scene to all who were obliged to seek health under the necessarily restricted conditions of a sanatorium life, and in this respect a "sea view" with the eternal contrasts of light and shade, and variety of colour and movement, offered advantages which no inland station could afford; and he had often wondered why so many sanatoria were founded inland to the comparative neglect of the sea coast.

Dr. CLIPPINGDALE expressed the view that a case of phthisis, in any stage of the disease, did better in a bracing climate than in a relaxing one.

Dr. LEONARD WILLIAMS said that it was necessary to draw distinctions between various kinds of marine climates. The climate of the north coast of the Isle of Thanet was as different, for example, from the south coast of Devonshire as the climate of high altitudes was different from the climate of the plains. It depended upon the type of tuberculous person which of these climates should be recommended.

Dr. EWART, in reply, explained that the bacilli could not be directly influenced by such slight oscillations of temperature or such moderate variations of climate as occurred within the temperate zones. But to their host these influences made all the difference. He entirely agreed with Dr. Street and other speakers as to the unequalled value of the bracing climate of Thanet; but it was apt to be too "strong" for the more advanced cases of phthisis, although invaluable in the early stage and in surgical tuberculosis.

THE CENTRAL MIDWIVES BOARD.

MEETING HELD THURSDAY, APRIL 18TH.

The President, Dr. CHAMPNEYS, in the Chair.

THE proceedings opened with the unanimous re-election of Dr. Champneys as president for another year.

THE PRIVY COUNCIL AND POOR-LAW INSTITUTIONS.

A letter was read from the Secretary of Privy Council stating that the rules as drawn up would be approved save that part of II. dealing with poor-law institutions as training schools.

Miss PAGET moved that this exception be accepted under protest, and only as *pro tem.* seeing that the old rule (C1) to continue had been found unsatisfactory in its working.

Dr. PARKER YOUNG said that it was merely a question of accepting the amendments or resigning their posts.

Sir WM. SINCLAIR remarked that to send a protest which would simply be shelved would be waste of time. Let the objections simply be entered for the benefit of the medical profession.

Mr. WARD COUSINS added that after the way the last resolution sent up was treated he agreed with Sir Wm. Sinclair that it would be more dignified to pass the matter over.

It was finally agreed to send a protest against exempting poor-law institutions from the supervision of the Board.

Miss PAGET moved that the name of Dr. Stanley Atkinson be added to the Penal Committee, and this was done.

THE IGNORANCE OF MIDWIVES AND PUERPERAL FEVER.

SIR WM. SINCLAIR after the reading of the report of the Penal Cases Committee remarked that a great many cases reported shewed slackness all round. There ought to be a rule that the temperature be constantly taken *and recorded*, as this was one of the best preventatives against puerperal fever.

Miss WILSON objected. There were, she said, some 12,000 midwives of whom 8,000 were incapable of doing this duty, and if the local authority had to report a lapse in its performance, it would give endless trouble.

Dr. PARKER YOUNG remarked, Sir Wm. Sinclair had expressed exactly what he was always urging. If these women could neither read nor write they had no right to be on the roll.

Sir WM. SINCLAIR added that it was not a case of the convenience of midwives, but one of life and death to patients. He did not mean the matter to rest. There were 3,000 deaths from puerperal fever alone. They could not take the responsibility of letting so many lives be lost.

Dr. PARKER YOUNG seconded Sir Wm. Sinclair, but the voting was against the motion.

Miss WILSON adding, that although she sympathized with Sir Wm. Sinclair, she must urge the cause of the poorer women in rural districts where midwives were hard to obtain.

Sir WM. SINCLAIR expressed a wish that his motion and the names of voters for and against be duly entered on the minutes. He also urged that in the appointment of a sub-committee the medical faculty be more largely represented. They were doing their medical colleagues an injustice by not so doing. He would like Dr. Parker Young's name added to the names of the President, Miss Paget, and Mr. Fordham (treasurer), who were soon to prepare a statement on the amendment of rules. Dr. Parker Young expressed willingness to meet them if his professional engagements allowed.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Apri 18th, 1907

TINEA CAPITIS.

Is tinea, or ringworm of the scalp, contagious? For a long time, tinea of the head was considered as a parasitic and contagious affection, more or less analogous to trichophyton. This theory was first set forth by Bazin (1862), and up to these last years unanimously accepted, the arguments being based on clinical, experimental, and bacteriological observations.

The bacteriologists affirmed the existence of specific germs in the tinea patches—bacteria, bacilli, &c. Unfortunately none of these germs have proved to be very virulent. The parasite discovered by Malassez

Eichhorst, was only a common saprophyte of the skin, while the micro-bacilli discovered by Sabourand never provoked ringworm by inoculation (Hallopean).

Experimental research was not more fortunate in proving the contagiousness of the disease. Each time an attempt was made, by inoculation, to transmit the malady to a healthy subject it failed (Jacquet). Only one case of positive inoculation is known (Blaschko), but this case was contested by the colleagues of Blaschko himself, and it can be said that up to the present every experimental effort has been unsuccessful.

As to clinical observations, they carry certain weight, but none of them were sufficiently precise to warrant discussion.

Some time ago, two Paris dermatologists published a case of ringworm epidemic observed in the police force. Four men, it was said, belonging to the same squad, were constantly together. Every second day they had to mount guard and relieve each other at fixed hours. In the interval of their turn to go on guard, they stretched themselves on a camp bed covered with a mattress and a pillow. In a short time all of them were found to be affected with ringworm of the scalp.

Here was positive proof of contagion, but a minute inquiry put everything in its place. The men affected were not constantly together, their turn to mount guard did not come every day but at long intervals, and in lying down they took particular precautions not to contaminate each other. If, then, they were affected with ringworm, it was by no means proved that contagion was the determining cause.

The theory of the anti-contagionists reposes on facts that may be divided into two classes—those of positive order and those of negative order.

To the first class belongs the success obtained in treating the ringworm according to the ideas of M. Jacquet, for whom tinea is but an ordinary lesion, a symptom caused by some irritation. Any local irritation, of no matter what nature, can provoke ringworm, on the condition that it attacks a pre-disposed individual; the *role* of this pre-disposition is considerable. Here it appears in the course of a well-defined malady (frequent in syphilis); there, on the contrary, it seems to develop independently of any disturbance of the general health, but the appearance is illusory. For when the patients are examined with care, it will be almost always found that the disease is associated with some morbid elements—troubles of the circulation, polyuria, hypophosphituria, albuminuria, seborrhœa, hyperhydrosis, or, on the contrary, anhydrosis, &c. However, none of these would be sufficient of themselves to provoke ringworm. Some cause of local irritation is necessary, and this is frequently due to dental lesion or the abnormal cutting of a tooth.

If this theory is exact, it is not necessary in order to cure the patients, to apply to the ringworm patch one or other of the famous antiseptic lotions or ointments; it suffices to stimulate the general condition of the patient and to treat the local irritation which provoked the malady.

It is thus, in fact, that M. Jacquet has treated systematically for several years the affection with almost invariable success. He asserts that this treatment cures more rapidly and more surely than any other method. He pleads consequently in favour of the neurotrophic theory of ringworm.

As to the negative facts, M. Jacquet made over one thousand attempts at inoculation under the most favourable conditions, without succeeding in provoking one case of the disease. Consequently he concluded that ringworm was not contagious and that there was no danger in allowing a person affected with the malady to mix with others.

His views have been adopted by many others, among whom may be mentioned, Besnier, Brocq, Daulos, Jeanseline, and Leredde. Professor Besnier, the well-known dermatologist of the St. Louis Hospital, was formerly an ardent partisan of the contagion theory, but to-day he has changed opinion. Professor Brocq is said to have sought during the last ten years, for cases of contagion, and was unable to find one authentic example. Jeanseline says: "For the ringworm is not contagious;" and Leredde, "Ringworm cannot be communicated."

The opinion, consequently, of the majority of contemporaneous dermatologists is that tinea is neither a parasitic, contagious, or epidemic affection. In accordance with these views, the Paris Board of Health has advised the Prefect of the Seine to remove the interdict touching affected school children; they are no longer isolated from their companions.

Ascites.

Calomel, grs. 2
Sugar, dr. 1

Divide into 20 powders. One every three hours. Each evening a tablespoonful of castor oil to expel the calomel. The treatment should not exceed four or five days.

Acne Rosacea.

Flowers of sulphur, dr. 6
Spirits of camphor, dr. 6

Paint on the face every evening with a pencil. The alcohol volatilises, leaving on the skin a layer of camphor and sulphur which can be washed off in the morning.

GERMANY.

Berlin, April 20th, 1907.

At the Verein für Innere Medizin Hr. Ewald showed A Spindle-Shaped Dilatation of the Œsophagus that had been diagnosed during life. Such a diagnosis was not often made with certainty. The patient was a man æt. 30, and the diagnosis had been made three years before. About a year and a half before his admission into the Augusta Hospital he had been suddenly attacked with vomiting in the night; after every meal he had had regurgitation, that now and then amounted to actual vomiting. Then one day he suddenly brought up a bright red mass of tissue that the medical man who attended him said came from an ulcer in the œsophagus. From that time the patient's condition changed, sometimes he could take food without any trouble, sometimes not; frequently he brought up remnants of food that he had taken days before. As carcinoma and organic stricture could be excluded there remained only either a diverticulum or a spindle-shaped dilatation of the œsophagus. The speaker then tried the various tests given by Rumpel, and the results were always in favour of the latter eventuality. By the constancy of the results obtained all the possible sources of error that attached to the experiment were eliminated. From the fact that the patient could sometimes swallow well and sometimes not at all and also from the circumstance that he could introduce the tube into the stomach himself it was clear that beyond the spasm there was no organic stricture. The size of the sac could be reckoned at about 400 cc.m., the food mass remaining in it, 250 cc.m. No products of digestion were found in this; in the stomach were some chlorides, but no free acid. The patient got gradually weaker, and at last died. The diagnosis in the determination of which œsophagoscopy by Glückmann's instrument and Röntgen illumination were made use of, was confirmed at the autopsy. The circumference of the unopened œsophagus was, below the bifurcation 5–6 cm., above 5 cm., the width of the opened gullet was above the cardiac end 4 cm., below the bifurcation 10 cm., above it 9 cm. The muscular coat of the walls was thickened to 3 cm. As regards ætiology the case confirmed the view that in idiopathic dilatation of the œsophagus two factors were necessary, first, spasm of the cardiac end; second, atony of the walls of the œsophagus.

Hr. Benda observed that some years ago he had examined the body of a man who had dilatation of the œsophagus that was diagnosed during life. He found then that there was an attachment of the œsophageal branch of the vagus to a lymph gland, which Kraus had noted as of ætiological moment.

Hr. Ewald replied that he had not overlooked that well-known point.

Hr. Schusler showed two patients who had been sent to him on account of eye symptoms. The first case was that of a man æt. 61, who four weeks before had found that he was blind in one eye. Examination showed atrophy of the optic nerve and rigidity of the pupil. He had suffered for about three years from nerve troubles, shown especially by trembling of the hands and feet. Ataxic symptoms were also present. The case was one of combination of paralysis agitans with locomotor ataxy. The second patient, æt. 33, had during the last few months become completely amaurotic, before then having hemianopsia. He had remarked lately that his gloves had become too small for him, and his rings would no longer go over his fingers. The nose was thickened and the facial expression had become peculiarly fixed. The case was one of acromegaly and the X-ray image plainly showed a good sized tumour of the hypophysis.

Hr. Ewald doubted whether there was any paralysis agitans in the first case as the tremor was an "intention" tremor, while the tremor of paralysis agitans ceased when intentional movements were made.

Dr. Schusler replied that Gerhardt, Junr., had published some cases of paralysis agitans with "intention" tremor.

At the Laryngological Society Hr. E. Meyer showed a child on whom tracheotomy had been performed for diphtheria. As the disease subsided there had been great difficulty with the "decanülement." The degree of stenosis and the winding of the canal and especially the fact that the retention of the intubattion cannula for twenty-four hours set up a sharp attack of bronchitis rendered all measures vain. Success was first obtained with Fischer's modification of O'Dwyer's tube of hard gum with a metal core, which could be retained for a fortnight without setting up any ulcer. The child even breathed well and spoke with a low voice.

At the Medizinisch Gesellschaft Hr. F. Friedlander spoke on

Antidotes to Poisoning by Lysol.

From the affinity of oil for kresol as observed by Blumenthal he had given lysol along with oil and other fats to rabbits. If he gave these soon enough, *i.e.*, before the onset of spasms they did not come on. He got the same effects from giving albumen. If the administration of the antidotes was delayed fifteen minutes or beyond it no longer did any good. For the antidote to be successful, five times as much of it as of the poison taken must be given.

At present there was no theoretical explanation of the paralysing of the kresol. Albumen coagulated with kresol, the coagulated mass was digested by pepsine-hydrochloric acid. Kresol taken internally was excreted mainly in the urine, but little by the bowel. In animals to whom the antidote had been given the excretion was much slower than in others.

In practise by far the best thing after lysol poisoning was to wash out the stomach as speedily as possible. Until this can be done oil in white of egg should be given, *in any case water should not be given.* After the washing out, oil or egg albumen should be given.

Hr. F. Blumenthal said that he could confirm what had been said. In treatment washing out was the first line from which success was sometimes obtainable, even when the patient was pulseless. After that the oil or egg albumen should follow.

Hr. Weinberg has used an oily mixture externally, and the skin bore lysol up to 60 to 80 per cent. without harm, so long as the part to which it was applied had been carefully dried. The moist skin was cauterized. Very much weaker solution of lysol in water acted as a caustic. Lysol-oil mixtures could be used on the skin when otherwise carbolic acid would be used.

AUSTRIA.

Vienna, April 20th, 1907.

Cerebro-Spinal Fluid.

Lehndorff and Baumgarten presented a report to the Gesellschaft on their examinations of twenty-five cases of cerebro-spinal fluid. It was alleged at a former meeting that the cause of meningitis was due to an accumulation of lactic acid in or about the nerve centres. To confirm or deny this opinion of Uffelmann the present report was desired. It now confirms the presence of lactic acid in every one of the cases, but refrains from saying this is the cause.

Zack added to this report by saying that he had obtained an ether extract of lactic acid from the cerebro-spinal fluid taken from cases of tubercular meningitis.

Leucocytosis and Serum Injection.

Bienenfeld next gave the results of his experiments with serum and albumen. After injecting a quantity of foreign albumen a pause of eight to twelve days occurs, when a typical rash, efflorescence, fever, swelling of the lymphatic glands, œdema, swelling of the joints, albumen in the urine, and general disturbance appears. In four of the cases daily numeration of the leucocytes was taken and the blood found to be in a state of leucopenia. This is the term used by Lowits where the white corpuscles have undergone leucolysis or destruction of the leucocyte, as was the case in his experiments after abnormally lowering the temperature. Goldschmidt obtained the same results by injecting the extracts of the spleen, thymus, and marrow of bone—a destruction of the leucocytes as opposed to the function of manufacture of the leucocyte. Bienenfeld found the leucocyte curve fall after giving this artificial serum of albumen he had prepared, and concluded that this lowered in some way the specific gravity of the leucocyte, and thus destroyed some constituent of the blood. In order to test this hypothesis he selected nine cases of scarlet fever and injected 100 to 200 centimetres of Mosers' Polyvalent Scarlatina Serum; also others with tetanus were injected with Behring's Tetanus Antitoxin for three or four weeks, and the leucocytes enumerated daily. Dried preparations were preserved for confirmation. The results of large doses were two-fold on the number of the leucocytes. First, immediately after the injection leucopenia, followed later by lecocytosis; secondly, there is also an increase of the leucocyte curve in the prodromal period of the serum, which sinks after six days with a serum eruption. From this point the number of leucocytes descends till an absolute leucopenia is produced, numbering 5,000 only in four days later. After all the serum phenomena have passed off the leucocytes return to the original number.

Bienenfeld agrees with Löwits that the leucopenia is the direct result of destruction in the blood by the serum, and not by nitrogen as affirmed by others. There is also a connection between this leucopenia and swelling of the glands, spleen, &c., as well as the formation of precipitine.

Schlesinger thought this an important question, and asked if we had this leucopenia in typhoid fever. For example, he had several cases under his own observation where the white corpuscles were only 3,000. He injected 130 cubic centimetres of serum, and four days later found the white corpuscles to be 14,000, which gradually rose later to 24,000. During this period all the phenomena of "serum disease" were present, viz., urticaria, articular swelling, albuminuria, and elevation of temperature.

Escherich believed there was a change in the blood after an injection of serum which could be demonstrated with the Röntgen Rays, but whether it was due to the serum checking the function of manufacture of white corpuscles or their destruction he would not like to say.

Bienenfeld remarked that there was a similarity between the serum injection and the action of the Röntgen Rays, as both produced leucopenia and an increase of the mononuclear leucocytes. He suggested the possibility of a degenerative change having been produced in this bone marrow.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

SERIOUS SHOOTING ASSAULT ON DR. JOHN CARSEWELL, GLASGOW.

It may be remembered that about two years ago, Dr. Carsewell, along with Dr. Marion Gilchrist, successfully, though at very great annoyance and financial loss, defended an action brought against them by a Clyde pilot, named Purvis, for erroneous detention in an asylum. Much sympathy was expressed for both Dr. Carsewell and Dr. Gilchrist at the time, and expressed itself in the substantial form of a fund to pay off part of their law expenses. Much regret will therefore be felt that Dr. Carsewell has again become a victim of the animus of the pursuer, who, on April 16, assaulted him in a most deliberate manner. About three o'clock, Dr. Carsewell left the Parish Hospital in Duke Street and proceeded westward to his residence. As he was stepping on to a car near Moore Street, he heard three sharp explosions and felt two sharp twinges in his left thigh. He fell helpless to the ground, and just as he did so saw a man with a smoking revolver in his hand. Duke Street was thronged at the time, but so suddenly was the outrage perpetrated that the first intimation anyone received was the sound of the revolver. The man was at once arrested, and was in a perfectly collected frame of mind. He gave his name as William Purvis, retired Clyde pilot, and on his way to prison talked quite freely. "I am guilty," he said. "My intention was to get the doctor into the witness-box again and to squeeze the truth out of him. I have lost £400 over him. He has ruined me." He added that he expected to get six or eight months for the affair. One version of the affair is that as Purvis fired at the doctor from a few yards' distance and saw him fall, he exclaimed, "Take that fool to the hospital." Happily it is thought that Dr. Carsewell's injuries are not serious. He has three wounds, one over the left buttock, one in the front of the left thigh and one in the right thigh. The bullet which struck the left thigh passed completely through, narrowly escaping the femoral artery. He passed a fairly easy day, and at the time of writing (April 18th) his condition is satisfactory. He is under the case of Sir William MacEwen. Purvis was brought before the magistrates on the 17th inst. and remanded. At a meeting of the Daily Relief Committee of the Glasgow Parish Council it was agreed to send a message of sympathy. The chairman said that the unfortunate occurrence opened their eyes to the fact that Dr. Carsewell, in the course of his duties, had disagreeable, and even dangerous, tasks to perform.

Milk Supply of Edinburgh.—A very important report on the milk supply of the city has been issued by the chief sanitary inspector, Dr. Williamson. The bacteriological work was carried out in the Usher Institute, and the organisms specially looked for were B. coli, B. enteritidis sporogenes, streptococci, and acrofast bacilli. A very large number of samples, representing many sources of supply, both in town and country, were submitted to examination. B. coli and B. enteritidis sporogenes indicate pollution during milking. The former increases rapidly in the milk, the latter does not, so that it may be taken as a measure of the original contamination. Streptococci are found in the dung of cows, and in various diseases of the udder; they are important as giving rise to sore throats, &c. Among the acrofast bacilli, B. tuberculosis is, of course, that which must be sought; other members of the group are found in grass, manure, &c. When acrofast bacilli were detected they were inoculated into guinea-pigs to ascertain their true nature. The average percentage of fat in these samples was: Railway milk (evening), 3.38; country milk (morning), 3.22; town milk (morning), 3.19, centrifuged sediment. The total solid contamination was greater than in Dr. Houston's specially collected London milk, in which no sample showed more than 25 parts per million. In town milk there were less than 25 parts per million in 66 per cent.; in country milks in 52 per cent., and in railway milks in 56 per cent. B. coli was found in all the samples examined; it was present in only 40 per cent. of Dr. Houston's specially collected London specimens. B. enteritidis was found in 47 per cent. of town milk, 28 per cent. of country milk, and 37 per cent. of railway milk. Streptococci were found in 30, 19, and 14 per cent. respectively. The most satisfactory result is the entire absence of tuberculosis in connection with any of the milks examined. The organisms found are those which are associated with dirt and manurial origin, and in the absence of efficient inspection it is not likely that greater freedom from contamination than is represented by these figures can be attained. Dr. Williamson makes the following recommendations to ensure greater purity: (1) At present milking is done in the byres in which the cows stand all day and night for months at a time. Milking ought only to be allowed in a separate milking shed apart from the byres. (2) The milk of recently calved cows should not be allowed to be sold. (3) The following regulations require revision—(*a*) The rule that no "direct" communication is allowed between a milkshop and dwelling-house is interpreted to mean that if there is a passage between the two it is permissible. This, of course, is wrong. (*b*) There is much confusion at present as to what articles the regulations allow to be sold in milk shops; many at present obtainable in such places contaminate the milk supply. (*c*) It ought no longer to be compulsory to register as milksellers all applicants, irrespective of their personal suitability or that of their premises. (4) The storage of manure in byres for fourteen days is allowed. It would perhaps be an ideal, but it ought to be removed every twenty-four hours. (5) The existing legislation is insufficient to ensure the seizure of tuberculous cows discovered in byres. Tuberculous milk is much more dangerous than tuberculous meat, which local authorities are empowered to destroy; yet under the existing regulations it is possible for the owner of a tuberculous cow to remove the animal from the district where it has been detected, and to transfer it to another locality, where it may legally be used for milk giving purposes until the condition has been detected by the officers of the district to which it has been transferred.

BELFAST.

Cerebro-spinal Meningitis.—During the last week, 30 new cases of cerebro-spinal meningitis were notified to the Public Health Office, and 23 deaths were notified to the Registrar-General, bringing the mortality up to 200. Apart from this epidemic there is less infectious disease than usual in the city. It is reported that Professor Symmers is doing some interesting work at the bacteriology of the infection in his laboratory at Queen's College, and has succeeded in cultivating the meningococcus for many generations. This has not been done hitherto, and is the first necessity for the preparation of a serum or antitoxin. At the forthcoming meeting of the Ulster Branch of the British Medical Association, which is to be held in Londonderry on Saturday, the 27th inst., there is to be a discussion on cerebro-spinal meningitis, in which Professor Symmers is to take part, so some information on his recent work may shortly be expected.

Holywood Water Supply.—The Urban Council of the little town of Holywood, in Co. Down, is constantly in trouble with the ratepayers over the water supply. Last week one indignant inhabitant reported to the authorities that he had found frogs, fish, and blood in his tap water. It sounded as though some modern Moses had been at work in the neighbourhood, reproducing the plagues of Egypt, but the matter appears to be no joke, for the sanitary sub-officer, when questioned about it, said that frogs and fish must have got into the main when the water-basin was cleared. Perhaps when a few of their first-born have died the Urban Council may take the matter vigorously in hand, and alter what is a disgrace to any civilised community in these days.

Belfast Health Commission.—The Commission has not sat during the past week, but is to sit again about the 24th, when it is expected that expert evidence will be taken on the water supply. Professor Symmers will give evidence as to its present character, while his predecessor, Professor Lorrain Smith will give evidence as to what he found during the severe typhoid epidemic of a few years ago. The Water Commissioners have had three experts busy for some time past making examinations and analyses, and they also will give evidence, so an interesting week may be anticipated.

LETTERS TO THE EDITOR.

MILK AND TUBERCULOSIS.

To the Editor of The Medical Press and Circular.

Sir,—Dr. Granville Bantock's statements and arguments in the letter in the Medical Press of April 17th are, like all his writings, interesting and even amusing. but they do not seem to take us much further—regarded from a practical point of view. He agrees that "it is probably correct that 'live' tubercle bacilli can be conveyed in milk," but seems to suggest that, although milk thus infected may be partaken of in any quantity, the danger of setting up tuberculosis in those fed upon it is never to be regarded seriously. Does he hold the same opinion with regard to milk containing the contagium of typhoid fever, for example? There are always a certain number of persons immune, and in cases where a typhoid outbreak is clearly demonstrated as due to milk infection, it always happens that a large percentage of those consuming the milk escape. No doubt the same thing occurs in tuberculosis, and the fact that this disease in every form attacks by preference the children of the poor is to be accounted for on many grounds. They live in surroundings of darkness, dampness and filth, strongly predisposing to the disease; whilst starvation from lack of food or from improper feeding increases their susceptibility. Surely we ought not to wait for a scientific demonstration of the entire sequence of contributory causes and of the mode of attack in tuberculosis, or any disease due to a specific contagium, but ought to set about to prevent the dissemination of the poison by every possible means. Until we shall have gained the means to stamp out tuberculosis in cattle we are surely bound, in light of our present knowledge, to do all that may lie in our power to prevent the consumption of infected meat, and of milk reasonably to be suspected of holding the specific poison. This, as I understand it, is all that you, Sir, are contending for; it is certainly that which will be striven for by most of us until better ways are indicated.

I am, Sir, yours truly,
A Family Doctor.

Bristol, April 18th, 1907.

OBITUARY.

WILLIAM HENRY RANSOM, M.D.Lond., F.R.C.P., F.R.S.

With regret we record the death of a well-known member of the medical profession in the person of Dr. W. H. Ransom, of Nottingham. Deceased, who was one of the oldest practitioners in the Kingdom, had been ailing for some months, although his end from heart failure came somewhat suddenly. He died at the age of 83, having graduated in 1850 M.D. of London, from University College, which he entered in 1843. He took the Fellowship of the London College of Physicians in 1869. Born at Cromer in 1823 he was educated at Nottingham, in which town he started practice in 1850. He engaged in some natural history research, which was published in the Transactions of the Royal Society, of which body he was made a Fellow in 1870. In 1854 he was elected physician to the Nottingham General Hospital, and he was connected with many other local medical institutions. In 1892 he was President of the British Medical Association. From his earliest days he opposed the popular view that cold was the cause of many maladies, and in this connection he was an early and consistent advocate of the open air treatment of consumption. Dr. Ransom lived a strenuous life professionally and socially. Space will not permit us to record his many spheres of usefulness and activity, which included volunteering, education, and local and general politics. He has left three sons, of whom one, Dr. W. B. Ransom, succeeded his father in practice on the retirement of the latter some eight or ten years ago. Among his friends Dr. Ransom numbered such men as Herbert Spencer and Huxley. His loss will be felt by a wide circle of friends and acquaintances, both within and without the medical profession.

JOHN LACY COLLISON-MORLEY, M.D., Brux.

The death, which occurred on April 10th, of Dr. John Lacy Collison-Morley, deprives St. Paul's School of one of its best friends. Dr. Collison-Morley acted as medical officer to the school, and practised in the neighbourhood for many years. He was an indefatigable collector of prints and engravings, and earned the gratitude of the school by his gift of a valuable collection of portraits of distinguished *alumni* of the school. To his original gift he made frequent additions, and it is largely due to his generosity that the school is able to maintain a sense of continuity with the old City school of Milton, Pepys, and Marlborough. Dr. Collison-Morley, who was formerly a lieutenant in the 20th Regiment, qualified from Guy's Hospital in 1872 and held the degree of M.D. of Brussels.

BEATTIE BAIN, M.D.Edin.

We regret to record the death of Dr. Beattie Bain, at Dundee on the 9th instant. He was born at Montrose, and after graduating at Edinburgh University, became Superintendent of Craiglockhart Hospital, Edinburgh. After a year he became assistant to Dr. Low, at Sandringham, where he came much into contact with members of the Royal Household. He then left for Bristol, where he held an extensive practice for ten years. Twenty-five years ago he settled down finally in Dundee where he took much interest in local educational and social matters. His death at the age of 68, removes an engaging and distinguished figure from his native town.

SPECIAL ARTICLE

THE UNIVERSITY QUESTION IN IRELAND

During the past week there have been the usual budget of protests against, and approval of, the supposed scheme of the Government for the improvement of University Education in Ireland. On Tuesday a quarterly meeting of the Standing Committee of the Roman Catholic Church in Ireland was held in Dublin, at which a long declaration and resolution were adopted and ordered to be published. The following paragraphs taken from it will give a fair general idea of the opinions expressed in it:—

"On the supposition, then, that the Government gives us an adequate and worthy scheme on any one of the three plans which we put before the recent Royal Commission, we, for our part, shall be prepared to accept it as final, and as the settlement, in our time, of the Irish University question. Of course, neither we nor anyone else can foresee what the natural development of institutions may bring with it, but on the condition just stated, as far as we are concerned, we shall consider the Catholic grievance as removed, and the whole question closed.

"At the present stage, as is obvious, we cannot go farther than this expression in general terms of our approval of the Government plan of a National University as the basis of a settlement. When a scheme, worked out in full detail, and showing its positive provisions both for the general interests of education, and for the special interests which it is our first duty to protect, has been formulated, we shall be in a position to pronounce a definite opinion upon its merits."

On the same day, in the House of Commons, Mr. Birrell, in answer to Viscount Castlereagh, said that the proposals of his Majesty's Government will proceed upon the lines indicated by Mr. Bryce, subject, it may be, as, indeed, he intimated, to modifications if found necessary, and that he was not yet in a position to name a date for placing before Parliament the Government proposals for dealing with Irish University Education.

A protest has been sent to the Government from members of the Galway Alumni Association protesting against "the attempt to place out Alma Mater in a position inferior to that of the other Queen's Colleges in the new University scheme of the Government."

Lastly, protests against the "Government Scheme" have been sent from Sheffield University and from St. David's College, Lampeter, whilst a resolution approving in general terms of the scheme have been adopted by the Irish County Councils General Council, a body which is representative of the Nationalist Councils throughout Ireland.

A memorial has also been sent to Mr. Birrell by eight hundred Ulster graduates, amongst whom are represented the Universities of Dublin, Oxford, Cambridge, London, Durham, Edinburgh, Glasgow, Aberdeen, and Freiburg, in Baden, also the Queen's University and the Royal University of Ireland. The memorial is also signed by Archbishops, Bishops, Peers, Baronets, Deputy-Lieutenants, military and naval officers, doctors, lawyers, and many influential representatives of the trade and industry of Ulster. The memorial protests against a scheme which will "inevitably lead to the ruin of the principal representative and exponent of modern thought and research in this country."

THE QUALIFICATION OF "MIDWIVES."

WE have commented in these columns over and over again on the extraordinary ideas which seem to be present in the minds of certain members of the Central Midwives' Board on the object of the Midwives' Act and of their duties as members of the Board. It may be trite, but it is none the less true, that the object of passing the Act was to secure the better training of Midwives, and to regulate their practice, in order that they might be a benefit instead of a curse to their patients. Consequently, it follows that the Act was not passed in order to promote the welfare of, no doubt, well-meaning, but dangerous, old and illiterate women. At the last meeting of the Central Midwives' Board, as reported in our columns to-day, Miss Wilson objected to a rule that the temperature of the patient should be regularly taken and recorded because there were some eight thousand registered women who were incapable of doing so! We speak subject to correction, but are we not right in thinking that this is the same lady who expostulated vehemently at the Central Midwives' Board on a previous occasion because certain members of the Board desired to make illiteracy a bar to registration? If we are correct, then it appears that Miss Wilson having secured the admission to the register of illiterate women now desires to make these women's capacities the standard by which rules "for the better training of midwives and to regulate their practice" are to be drawn up! The Central Midwives' Board is receiving scant courtesy at the hands of the Privy Council, although on the point involved it is acting in accordance with the principles on which it was created. How can it, however, persuade a body of eminent laymen that it is doing so, when over and over again it is hopelessly and publicly stultified itself. We fear that, in its conflict with the Privy Council, the legitimate aspirations of the Board will suffer because of its absurd conduct in the past.

REVIEWS OF BOOKS.

THE CLINICAL SOCIETY'S TRANSACTIONS.(a)

THESE transactions are always most readable and full of interest, and the present volume, which represents the work done in the year 1905–1906, is no exception to this statement. It contains thirty-five papers of varying length on clinical cases, and in addition fifty-two short records of cases shown at the meetings of the Society. Its papers, taken as a group, are illustrated by twelve plates, and twenty-six other illustrations. The general character of the volume is unchanged, the paper, printing, and general binding being, as usual, everything that is to be desired. Out of so many articles of merit it is difficult to select any deserving special comment more than others, and so we must content ourselves by referring to a few, while premising the fact that many not mentioned are equally excellent. Amongst the purely medical papers, that by French and Ticehurst on "The Relation of Traumatic Diabetes Insipidus to Glycosuria" throws some light on the general pathology of diabetes. The case was that of a man who received a severe head injury in 1901, and thereupon developed extreme polyuria, without glycosuria. Attempts were made to produce alimentary glycosuria by feeding with large quantities of carbohydrates, but without success. The patient then left hospital, but returned three years later with extreme glycosuria and almost complete carbohydrate intolerance. Treatment had very little effect on the glycosuria; but the condition again disappeared spontaneously a year later, the polyuria and polydipsia, however, persisting. As the writers point out this type of case is very rare, and they have only been able to find one similar one recorded. Dr. Samuel West has contributed two short papers—one on "Periostic Respiration" as distinct from Cheyne-Stokes breathing, a condition which, he believes to be of much less prognostic importance than Cheyne-Stokes breathing, and which he believes to be only found in cases of basal meningitis; the other on a peculiar pleural effusion. A paper by Dr. Bax entitled "A Series of Cases in which Pulmonary Embolism appeared to be due to the Displacement of a Thrombus in the Main Trunk of the Pulmonary Artery" is more entertaining than convincing, though we have no doubt that pulmonary thrombosis and subsequent embolism does occasionally occur. The surgical papers are this year more numerous than usual, and considerable attention seems to have been drawn to cases of unusual varieties of hernia, as four out of the thirty-five articles deal with the subject. Peritonitis in typhoid fever, apart from perforation, seems also to have attracted attention, and judging from the cases published in this volume and elsewhere would seem to be more common than is usually believed. Another interesting intra-abdominal condition on which a paper appears is "Suppurative Pylephlebitis" secondary to suppuration within a mesenteric gland. Amongst the most interesting of the cases exhibited we may mention the following:—Adiposis Dolorosa; Extreme Obesity with Precocious Puberty in a girl æt. 3; Mediastinal Dermoid; and Myasthenia Gravis. The volume well repays perusal, and is an interesting exposition of the current of medical thought during the last twelve months.

(a) "Transactions of the Clinical Society of London." Vol. xxxix. London: Longmans, Green and Co. 1906.

Weekly Summary of Medical Literature, English and Foreign.

Specially compiled for The Medical Press and Circular.

Acute Dilatation of Stomach and Intestines in Peripheral Neuritis.—Dr. Parkes Weber reports a case of the above (*Edin. Med. Journ.*, April 1907, page 315). The patient, a man, æt. 50, was admitted to hospital with the typical signs of peripheral neutritis, probably alcoholic in origin. At first he did not present any serious symptoms, but after he had been under observation for a couple of days, he began to suffer from severe abdominal pain and had an attack of vomiting. The abdomen soon became distended, and the pulse rapid and feeble, so that it was thought advisable to perform a laparotomy on the supposition that acute pancreatitis was present. The patient however died suddenly under the anæsthetic (ether) before the operation was commenced. At the autopsy practically nothing abnormal was found except gaseous distension of the stomach and intestines, more especially the latter. The writer suggests that this distension may have been due to neuritis of the vagus nerve, leading to a sort of paralytic atony of the bowel wall. He points out that section of the vagi in the dog leads to intestinal dilatation and thinks that both it and the condition found in the present case is similar to paralytic distension without peritonitis, so often found after severe abdominal operation. M.

Obscure Renal Hæmaturia.—An interesting paper with the above title is contributed to the *International Clinics* (Vol. IV., 16th Series, page 122), by Elliott. He points out that it has been the experience of most surgeons to cut down more than once on kidneys for the relief of hæmaturia, and to find nothing abnormal. Various names have been applied to such cases, such as "renal hæmophilia," and "essential renal hæmaturia," but the present writer prefers the above individual title. Various theories also have been advanced to explain the occurrence, but none entirely satisfactory, although at one time considerable credence was given to Klemperer's view, that the bleeding was the result of paralysis of the vasoconstrictor nerves of the kidney, resulting in vasodilatation and consequent diapedesis of the blood elements. The aim of the present paper is to show, by allusion to cases, that in almost every instance some local renal lesion is really present. Among the local lesions he most frequently found chronic nephritis, which may be unilateral, or may even involve a part only of one kidney. Another lesion occasionally found is an angiomatous condition of the capillary blood vessels in the pelvis of the kidney; while occasionally simple movable kidney may prove the cause of intermittent hæmaturia. Till every case is thoroughly investigated, the existance of a purely functional hæmaturia should be regarded as non-proven. M.

An Unusual Form of Tabes Dorsalis.—Lapinsky (*Deutsche. Zeits. fur Nerven Zeilk.* Bd. 30, 3-4) describes a rare form of locomotor ataxia, which he has met with in five cases, and in which in the early stages pain, paræsthesia, and in fact, all sensory disturbances are absent. The first complaint is in fact of weakness, sometimes felt all over the body, but more especially in the legs, and frequently the weakened parts show some atrophy. The weakness may be present in all the muscles of the extremities or special nerve muscle groups may be picked out. Ataxia is not a very prominent symptom, but is present more or less in all movements. In the later stage of the disease all the typical phenomena of tabes dorsalis develop. The writer first thought that the primary weakness signified some disease of the anterior cornual cells, but microscopical examination in some instances proved these cells to be normal and, in consequence, the conclusion is drawn that the paralysis is centripetal in origin and due to a loss of muscle tone. M.

Neuronal as an Hypnotic.—Gerlach and Dreyfus report their clinical experience with neuronal (*Munich Med. Woch*, 1906, No. 21, and *Therap. Monat.*, May, 1906). They find that in cases of simple insomnia this drug, the chemical nature of which is expressed by the name bromid-ethylacetamid, is most useful in doses of ½ to 1 gramme, while in cases of nervous excitement doses of from ½ to 2½ grammes almost invariably produced quietude. Occasionally untoward results follow its use, more especially headache and acceleration of the pulse. Gerlach experimented with it in cases of epilepsy and found the fits diminished in number during its use. The diminution, however, seemed to be due, rather to the hypnotic effect of the drug than to any specific effect. M.

The Diaphragmatic Reflex.—Hess (*Münch. Med. Woch*, 1906, No. 36) understands by the term "diaphragmatic reflex" a slight contraction of the sternal part of the diaphragm leading to sucking in of the ensiform cartilage, and induced by stroking and tapping lightly the nipple. It appears to the observer as a very rapid but slight sinking in of the upper portion of the epigastrium, and resembles in consequence the epigastric reflex. It must, however, be distinguished from this last named, which can be induced by stroking the skin at the side of the thorax between the third and the sixth rib, and which is due to contraction of the rectus abdominis and external oblique muscles. Hess believes that the reflex path for the diaphragmatic reflex is not through the phrenic nerve, but is through the fifth intercostal, and he maintains that the phrenic nerve only supplies the posterior part of the diaphragm, the anterior part receiving its nerve supply from the lower intercostals. M.

Trypsin in Cancer. — W. Carter ("Therapeutic Notes") (*Liverpool Med. Chirurg. Jour.*, March, 1907), by way of reply to an oft-repeated question, "Do you consider trypsin of any value in the treatment of cancer?" gives the following case in which in consultation with Dr. MacAfee, he advised the use of trypsin owing to the beneficial effects reported to him in two apparently similar cases of uterine cancer:—"Patient æt. 51, unmarried had panhysterectomy performed for adenocarcinoma of the uterus. The left ovary was found to be seriously involved, considerable infiltration had taken place into the tissues around and from soon after the time of operation—in July, 1900—up till the beginning of 1905, it was evident that the disease was making progress in the pelvic region; a considerable mass could be felt in the left groin, and a large ulcer formed in the posterior wall of the rectum. This soon necessitated colotomy, which was performed in March, 1905. The patient was much relieved by this operation till August, when several alarming syncopal attacks occurred, and there was much exhaustion; pain in the pelvis was intense, and frequent discharges from the rectum took place with symptoms of septicæmia. The patient became steadily worse; increasing weakness, with symptoms of absorption and constant distress from the activity of the rectum, notwithstanding the injection of local sedatives, pointed to a rapidly fatal termination. On February 19th the use of trypsin was commenced. Two drachms of the liquid trypsin co. (Allen and Hanbury's) made up to one ounce, with water, were injected (into the rectum) daily, and one drachm three times a day administered by the mouth. There was an immediate improvement in both the local and general condition. The sense of urgent pressure ceased and the general increase of comfort was most gratifying. Sleep returned, the digestion improved and wasting was checked. The abdomen became less tender, and a marked diminution of the resistance in the left groin became evident; and in a month the patient was able to get out of a bed to a chair, and several times during the summer she has been able to take drives of considerable length. Such is Dr. MacAfee's report, and in order to learn whether the improvement continued, I telephoned to him for information, as these notes were being prepared for the press. The reply was in the affirmative. When it is remembered that the act of sitting up in her bedroom even, much less of going downstairs, and less still of driving out of doors, would not have been thought possible ten months previously, and, moreover, that a microscopic examination had determined beyond question that the growth was an adenocarcinoma, this case seems to point to the possible power that may be possessed by trypsin of differentiating between one form of cancer and another. It may perhaps be added that the matter discharged (from the colotomy entrance) after the injection of trypsin (into rectum) was alkaline in reaction, very albuminous and contained trypsin; but as 20 fl. oz. were sometimes discharged while only 1 fl. oz. of the trypsin solution was injected, it obviously contained very much more. Whether the additional fluid discharged was the result of any solvent action produced by the drug upon the cellular or other elements of the growth, must be matter of conjecture. What is not matter of conjecture, however, is the very great improvement in the patient's condition which followed, and, as we think, was caused by the treatment."

Lobar Pneumonia.—Affleck (*The Scottish Med. and Surg. Journ.*, April, 1907) discusses the question as to whether this disease has assumed a graver character of recent years, and whether the mortality rate is rising. From his clinical experience extending over some forty years he is inclined to answer the question in the affirmative, He is unable to recall that his teachers regarded pneumonia with the anxiety with which it is now looked upon, and finds from the returns of the Registrar-General of Scotland that the death-rate has been steadily rising since 1880. In that year the rate was 86 per 100,000, in 1890 it was 123, in 1900 it was 141, and in 1902 reached 155. Some interesting figures are also given from the Annual Reports of the Medical Registrar of the Edinburgh Royal Infirmary to show the high rate of mortality of pneumonia among alcoholics. Thus in 1899–1900 of 19 alcoholic pneumonias 17 died; in 1900–1901 of 5 all died, and in 1901–1902 of 22 cases 18 died. K.

The Nature of Diabetes Insipidus—Seiler (*Zeit f. Klin. Med.*, Berlin, 1907) concludes from his clinical and experimental experiences that diabetes insipidus is the result of an anomaly in kidney functioning which consists in the fact that the kidneys are no longer able to secrete urine of a normal concentration. The concentration is always below normal. If sufficient fluid is not ingested, then the elements of the urine are retained and trouble follows. To obtain sufficient fluid for the purpose Nature calls for increased intake of fluid by increased thirst, and satisfying the thirst leads to the polyuria. This may possibly be the cause also of the polyuria observed with contracted kidney. It might be possible, he suggests, to influence the diabetes favourably by diuretics to improve the secreting conditions in the kidneys. D.

Multiple Neuritis Simulating Progressive Muscular Atrophy.—Grinker (*Journal of the Am. Med. Assoc.*, March 9th, 1907) reports three cases, one of alcoholic polyneuritis, one of lead paralysis, and one of progressive muscular atrophy, illustrating the futility of attempting to differentiate these conditions by objective symptoms alone, without study of the etiology and course of the disease. Grinker holds, nevertheless, to the advisability of clinically separating the cornual from the peripheral lower neuron disorders. His conclusions are given as follows:—(1) Clinically, multiple neuritis may simulate a spinal atrophy as regards distribution of paralysis, absence of sensory symptoms and protracted course. (2) Progressive spinal muscular atrophy may resemble neuritis in the presence of pain, remission of symptoms and subacute course. (3) Etiology and course are still the best guides in the clinical diagnosis of the various muscle atrophies. D.

Leukæmic Blood Picture in a Case of Fracture of the Ankle.—Simon (*Am. Journal of Med. Science*, March, 1907) reports a case in which after fracture of the ankle the blood had the characteristics of that of myelogenous leukæmia. Six months later the blood had returned to normal condition. D.

Salt-Free Diet in Nephritis.—Peabody (*Med. Record*, March 9th, 1907) emphasizes the importance of the dechloridation treatment in cases of general anasarca from chronic parenchymatous nephritis with failing heart power. He says that its effect is perhaps enhanced by the simultaneous administration of heart tonics, such as digitalis and theobronim—preferably the latter. Peabody says that while clonic irrigations with hot sodium bicarbonate solution and catharsis are of value in some cases, the most important agent is the negative one referred to. After complete removal of the edema he administers progressively increasing daily quantities of salt, carefully watching for any recurrence of the edema, the endeavour being to ascertain the exact salt equilibrium for each patient. He is not yet prepared to report results. D.

Epidemic of Acute Anterior Poliomyelitis Occurring in Sweden During 1905.—Lundgven (*Hygiea, Stockholm*) traces the clinical picture of the disease as observed in 147 cases in the Växjö district. There were 403 cases in the entire epidemic which commenced in April, and reached its highest point in August and September; no case has been known since the beginning of 1906. The incubation seemed to be about 8 or 10 days, and a prodromal period followed, lasting from 1 to 3 days, with headache, vomiting, stiffness in the back of the neck, pains in the back, fever, and somnolence in the smaller children, with convulsions in some cases. The symptoms subsided after a few days, leaving a certain weakness in the arms or legs, and a staggering gait in some cases. In the majority, however, as the initial symptoms subsided, a gradual paralysis was observed, with paresis of the bladder, and in one case, disturbances in sight and in another of hearing, with loss of speech in a number. The mortality was about 10 per cent. Permanent paralysis was left in about 25 per cent. of the cases. D.

Ferments for Disinfection of the Intestines.—Fournier (*Presse Medicale, Paris*, 1907) says that the ideal disinfectant for the intestines would be an anaërobic ferment able to transform sugar into formic acid, but nothing of the kind is known. Brewers yeast answers some, but not all of the desired conditions for a disinfectant, and it frequently fails to exert any action, while the generation of alcohol is not always desirable, and the yeast is not resistant enough to act along the entire length of the digestive tract. The only ferment known to date which adapts itself anaërobic conditions and acts directly on the carbohydrates, while very resistant to external influences, is the lactic ferment. The combination of the lactic streptococcus and the lactic streptobacillus in symbiosis is proving an efficient and reliable means of disinfecting the intestine. D.

Medical News in Brief.

The London Hospitals' Saturday Fund.

The annual meeting of this Fund was held on Saturday last at the Mansion House, the Lord Mayor of London presiding over a crowded attendance, which included the medical officers of several of the London boroughs. The report of the council showed that the income of the fund in 1906 was £26,460, as against £25,930 in 1905, an increase of £530. The board of delegates had sanctioned the distribution of the sum of £23,898 among 205 institutions as follows:—General and special hospitals, £16,241; convalescent homes, £1,469; dispensaries, £911; Distribution Committee, £2,550; Surgical Appliance Committee, £1 500; Ambulance Committee, £111; miscellaneous institutions, £1,116. This was the largest sum ever distributed in one year, and exceeded that distributed in the previous year by £267.

The Lord Mayor having briefly alluded to the work of the fund, the adoption of the report was moved by the Right Hon. Sir Savile Crossley, Bart., president of the fund, and seconded by Archdeacon Sinclair, and carried, after which the Lady Mayoress presented a number of medallions and diplomas of merit awarded for efficient first-aid work during the year, and Dr. Wynter Blyth read an interesting address on "Sanitation."

The Medical Attendants to the Royal Irish Constabulary.

In the House of Commons on Wednesday last, Mr. Sloan asked the Chief Secretary for Ireland whether he was aware that the staff of medical attendants in Belfast was reduced from five to four, while the strength of the Belfast constabulary had substantially increased; would he state how many of the four medical attendants resided within their districts; whether he was aware that in Cork city the police medical attendant for the northern portion of the city lived on the south side, and the medical attendant for the south side lived on the north side; would he say if the surgeon to the force exercised any supervision over the medical attendants to the Royal Irish Constabulary all over Ireland; and, seeing that the police themselves paid these attendants a gross sum of about £10,000 a year out of their salaries, whether he would arrange that they should have some voice in their selection.—Mr. Birrell replied: In 1904 the number of medical attendants upon the police in Belfast was reduced from five to four upon a redistribution of stations in the city. Formerly there were but two medical attendants in Belfast. Three out of the four reside within their districts. In the remaining case this is not possible. The fact as to the places of residence of the medical attendants for Cork is as stated in the question. The surgeon to the force who is attached to the depot does not exercise supervision over the medical attendants throughout the country. The cost of medical attendance on the constabulary is not provided by the men but is borne on the votes. In the circumstances there do not appear to be any grounds for giving the men a voice in the selection of their medical attendants.

Society for the Relief of Widows and Orphans of Medical Men.

At a Quarterly Court of the above Society on Wednesday, April 10, Sir Thos. Smith, Bart., vice-president, in the chair, proposals for membership of the Society were read from three candidates, and they were duly elected. Since the last Court two members have died. Applications for relief were received from two widows of deceased members, and grants at the rate of £50 per annum each voted. One widow, who was left in very indigent circumstances, received an immediate grant of £10 10s. over and above the annual one. Eight letters had been received from the widows of medical men, during the past three months, asking for relief, but this had in each instance to be refused as their husbands had not been members of the Society. Any registered medical practitioner, residing at the time of his election, within a 20-mile radius of Charing Cross, is eligible for membership, full particulars and proposal forms may be obtained from the Secretary, at the offices of the Society, 11, Chandos Street, Cavendish Square. The date of the Annual General Meeting was fixed for Thursday, May 9th.

Philip Walker Studentship in Pathology.

The Professor of Pathology, Oxford University, announces that an election to this Studentship will take place in October next. The Studentship was founded "for the furtherance of original research in Pathology." It is of the annual value of £200 (payable quarterly in advance), and is tenable for three years. The Student may be of either sex and need not necessarily be a Member of the University of Oxford, nor be legally qualified to practise the profession of medicine. While holding office the time of the Student must be devoted to original Pathological research, and if the work done be of exceptional promise, the Studentship may be extended for a second period not exceeding two years. Intending candidates are requested to send letters of application, along with three testimonials (one of which should vouch for the candidate's personal character and general education), so that these shall be delivered to "The Registrar of the University, Oxford," on or before September 14th. The full text of the regulations relating to the Studentship will be found in the *Oxford University Gazette* for February 2nd, 1904, and copies of these Regulations can be had on application to the Registrar.

PASS LISTS.

University of Aberdeen.

The degree of Doctor of Medicine (M.D.) has been conferred on the following:—Alex. Callam, M.B., Ch.B., Burnley, Lancs. Thesis—"A Clinical Investigation of the Relative Efficacy of the so-called 'Organic' Iron Compounds in the treatment of Anæmia" (with commendation); John Conry, M.B., C.M., Fort Beaufort, Cape Colony (thesis for M.B. under old regulations); Arthur W. Falconer, M.B., Ch.B., Stonehaven. Thesis—"The Etiology and Symptoms of Gastric Ulcer" (with honours); Alex. Thomson, M.B., C.M., Fochabers. Thesis—"Rickets." (Under old regulations.)

Degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.).—With Second Class Honours.—*Norman Stephen Gilchrist, M.A., Newseat, Rothienorman; *Robert Williamson Asher Salmond, 469, Union Street, Aberdeen; Williamina Abel, David Anderson, M.A., William Angus, James William Barnett, Agnes Valentine Baxter, M.A., B.Sc., John Stott Beedie, B.Sc., James Alex. Clark, Andrew Coleman, James Alex. Davidson, James Donaldson, Robert Philip, Herbert W. Glashan, Leighton Hill Hay, James Hunter, Adam Hutton, Harry Middleton, George Mitchell, James E. Mitchell, John P. Mitchell, John Hay Moir, Alfred James Pirie, James Robertson, M.A., Alex. Hugh Skinner, M.A., John Paton Stuart, Frank Pearce Sturm, James E. G. Thomson, James I. P. Wilson. *Passed Final Professional Examination "With Distinction."

Diploma in Public Health.—Alexander Grant Anderson, M.A., B.Sc. (Aberd.), M.B., Ch.B. (Edin.), Aberdeen; Frederick Arthur Foy, M.B., C.M. (Aberd.), India; John Jenkins, M.A., M.B., Ch.B. (Aberd.), Burghead; Arthur Kellas, M.B., Ch.B. (Aberd.), Aberdeen; Forbes Jackson Stuart, M.B., Ch.B. (Aberd.), Aberdeen.

Royal College of Physicians of Ireland.

At a stated meeting of the President and Fellows of the Royal College of Physicians of Ireland, held on Friday, April 5th, Dr. William Roche, L. and L.M., K.Q.C.P.I., 1867, was admitted to the Membership of the College.

NOTICES TO CORRESPONDENTS, &c.

☞ **CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

MILK AND TUBERCULOSIS—A CORRECTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I shall be much obliged if you will be good enough to correct a misprint in my letter of the 12th inst. Thus, for "real nutrition" substitute "mal-nutrition."—I am, Sir, yours truly,

GEO. GRANVILLE BANTOCK.

14 Upper Hamilton Terrace, N.W.
April 19, 1907.

BUTH.—Adhesion of a persistent pupillary membrane to the cornea is, of course, very rare, but you will find it described as having occurred in the eye of a cat in the Report of the Ophthalmological Society published in Dec. 26th number of THE MEDICAL PRESS AND CIRCULAR last year.

LEX.—Yes, it is a way Lord Chancellors have, but we hope better things of Lord Loreburn. As to dates, a deputation of the London County Council, asking for amendments of the law of Death Certification and of the Coroners' Act, waited on Lord Herschell in February, 1895, the speakers being Sir E. Harris and Dr. Job Collins. Another deputation of the Council waited on Lord Halsbury in November, 1896, but that gentleman is known to have regarded this as such a good world that it needs little amending, and he not only did not take the opportunity presented by nine years of office, but he took very little notice of other representations made directly to him by the medical practitioners of London.

CLIMATO-THERAPY AT BUXTON.

THE following extract from the annual report of the Devonshire Hospital, Buxton, suggests some new principles in climato-therapy :—

The air of Buxton, resting on the large area of the mountain limestone and millstone grit formations, at an elevation of 1,000 feet and upwards above the sea level, must be an important factor in enhancing the health advantages of the situation of the hospital; and the sanitary position that has been secured by the efficient drainage and sewerage of Buxton, and its conveyance to a distance from the town; and complete chemical defœcation, and the destruction of all remaining refuse in a powerful furnace, must have completed the sanitary advantages, and lessened beyond calculation the risks of zymotic or epidemic disease.

DR. DAVID T.—The address of the Medical Defence Union is 4 Trafalgar Square, London, and that of the London and Counties Medical Protection Society is 31 Craven Street, Strand. The former is the older institution but either would probably answer your requirements.

MANCHESTER.—Your patient will be able to obtain any kind of bath you find it desirable to prescribe either at Matlock or Matlock Bath. The two places are about a couple of miles apart, and the system of baths, both at Smedley's Hydro, Matlock, and the Royal Hotel at Matlock Bath, is perfect. Each is under medical supervision, the former would, perhaps, be more congenial to a younger patient requiring amusement, the latter one being more suitable for one requiring absolute rest amid charming surroundings.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, APRIL 24th.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.).—8 p.m.: Annual Meeting. 8.30 p.m.: Adjourned Discussion on Epilepsy (opened by Dr. R. Russell). The following gentlemen will speak: Dr. W. S. Colman (Epilepsy in Children), Dr. A. Turner (Treatment of Epilepsy), Dr. H. Campbell (Diet in Epilepsy), Dr. C. H. Bond (Epileptic Colonies).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. P. J. Freyer: Clinique. (Surgical). 5.15 p.m.:—Lecture:—Dr. J. J. Perkins: Cyto-diagnosis (with lantern slides).

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—Cliniques:—2.30 p.m.: Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Out-patient (Dr. Whipham).

THURSDAY, APRIL 25th.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. E. Clarke: The Fundus Oculi in Health and Disease (with lantern slides).

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques: Fevers (Dr. F. Thomson at the North-Eastern Fever Hospital, St. Ann's Road, N.), Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson). 3 p.m.: Medical In-patient (Dr. Chappel).

FRIDAY, APRIL 26th.

BRITISH ELECTROTHERAPEUTIC SOCIETY (11 Chandos Street, Cavendish Square, W.).—8 p.m.: Council. 8.30 p.m.: Stereoscopes will be shown by Mr. C. A. Clark and Mr. A. D. Reid and a Simple Negative Viewer will be shown by Dr. G. B. Batten. Communication:—Dr. G. B. Batten: Simple Method of Epilating the Whole Scalp by Exposure to X Rays. Discussion on Dr. S. Sloan's Paper read at the meeting in February.

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8 p.m.: Clinical Evening for the Exhibition of Cases followed by Discussion. Patients in attendance from 8 to 9 p.m.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Dr. D. Grant: Clinique. (Ear.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—9.30 a.m.: Clinique. Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. Leslie).

Vacancies.

Inverness District Asylum.—Junior Assistant Medical Officer. Salary £100 per annum, with board, lodging, and laundry. Applications to the Medical Superintendent, District Asylum, Inverness.

Cameron Hospital, West Hartlepool.—House Surgeon. Salary £100 per annum, with board, rooms, and washing. Applications to J. G. Taylor, Secretary.

Weston-super-Mare Hospital.—House Surgeon. Salary £100 per annum, with board and residence in the Hospital. Applications to the Honorary Secretary.

Bradford Royal Infirmary.—House Surgeon. Salary £100 per annum, with board and residence. Applications to John Barron, Secretary.

County Borough of Warrington.—Medical Officer of Health. Salary £450 per annum. Applications to J. Lyon Whittle, Town Clerk, Town Hall, Warrington.

West Riding Asylum, Menston, near Leeds.—Fourth Assistant Medical Officer. Salary £150 per annum, with board and apartments. Applications to the Medical Superintendent.

Bradford Royal Infirmary.—House Physician. Salary £100 per annum, with board and residence. Applications to John J. Barron, Secretary.

County Borough of Derby.—Assistant to the Medical Officer of Health. Salary £120 per annum, with board and lodging. Applications to the Medical Officer of Health, Ford Street, Derby.

Edinburgh Provincial Committee for the Training of Teachers.—Lecturer on School Hygiene and Medical Officer. Salary £400 per annum. Applications to the Director of Studies, Training College Buildings, 16 Chamber Street, Edinburgh.

West Riding Asylum, Wakefield.—Pathologist and Assistant Medical Officer. Salary £140 per annum, with board, furnished apartments, washing, and attendance. Applications to the Medical Director.

Appointments.

DOBIE, CYRIL, M.B., M.S.Edin., Honorary Assistant Surgeon to the Chester Infirmary.

GOMES, SIDNEY, F.R.C.S.Edin., L.R.C.P.Edin., L.F.P.S.Glasg., Clinical Assistant to the Chelsea Hospital for Women.

HAMILTON, A. DOUGLAS, Honorary Assistant Physician to the Chester Infirmary.

KELLY, CHARLES ERNEST MACKENZIE, M.D., M.S.Lond., F.R.C.S.Eng., Medical Officer and Public Vaccinator to the Witney District and Workhouse.

MARTIN, ANTONY ALEXANDER, M.D.Lond., B.S., M.R.C.S., L.R.C.P.Lond., D.P.H.Lond., Honorary Assistant Medical Officer to the Princess Alice Memorial Hospital, Eastbourne.

MAYOU, M. STEPHEN, F.R.C.S.Eng., Assistant Surgeon to the Central London Ophthalmic Hospital.

ROBERTS, GEORGE A., F.R.C.S.Eng., Assistant Surgeon to the Royal Albert Hospital, Devonport.

ROMER, R. L., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Act for the Stanmore District of the county of Middlesex.

Births.

ANDERSON.—On April 18th, at Sanfield, Braunton, North Devon, the wife of Frederick T. Anderson, M.D., of a son.

BROWN.—On April 15th, at 2 Park Road, West Kirby, Cheshire, the wife of Wm. McIntyre Brown, M.B., Ch.B., of a daughter.

HUGHES.—On April 18th, at South Terrace, Littlehampton, the wife of Edgar A. Hughes, F.R.C.S., of a daughter.

TINDALL.—On Sunday, April 21st, at 5 Tenby Mansions, Nottingham Street, London, W., the wife of A. A. Tindall, junr., of a daughter.

Marriages.

BURROUGHS—TWYCROSS.—On April 10th, at the Parish Church, Brighton, Hastings Burroughs, M.R.C.S., 3 Elgin Park, Redland, Bristol, eldest son of the late Rev. W. G. Burroughs, Rector of Kilbeacon, Waterford, to Honora Mabella, only daughter of the late George Twycross, Esq., and of Mrs. Twycross, 23 Marine Square, Brighton.

PECK—BUTLER.—On April 20th, at St. Luke's, Camberwell, Grover Scarr, second son of the late Thomas Peck, Esq., M.D., of Alford to Mary Crawford, daughter of Capt. Butler, of 37 Victoria Road, Upper Norwood.

Deaths.

BENNETT.—On April 16th, at the Hollies, Clarence Road, Tunbridge Wells, Thomas Jarvis Bennett, M.D., formerly of Wilton, near Salisbury, aged 77.

HOWLETT.—On April 18th, at 191 Sutherland Avenue, London, Eleanor Maria Howlett, widow of the late Henry Howlett, F.R.C.S., in her 86th year.

RANSOM.—On April 16th, at 17 Park Valley, Nottingham, William Henry Ransom, M.D., F.R.C.P., F.R.S., aged 83.

RUDGE.—On April 15th, at Chur, Switzerland, Edwd. John Henry Rudge, M.R.C.S., L.R.C.P., aged 34.

SPOKES.—On April 20th, at Brighton, Agnes, the beloved wife of Peter Sidney Spokes, J.P., M.R.C.S., L.D.S., of 4 Portland Place, London, in her 43rd year.

WOODWARD.—On April 18th, at Pershore, Worcestershire, Ada Bridget, the third daughter of Martin Woodward, M.R.C.S., and Mrs. Martin Woodward, aged 41.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIV. WEDNESDAY, MAY 1, 1907. No. 18

NOTES AND COMMENTS.

Shaving without Razors. LAST week quite a flutter was caused by the announcement that in future razors would be superfluous, and that a smooth chin could be obtained in the morning by means of a mysterious powder which would soften the beard, and a paper-knife which would sweep it away with a few brief strokes. Fanciful pictures were drawn of the added comfort which would accrue to the matutinal toilet, and the extra time that might legitimately be devoted to snoozing after the hot water was brought to the bedroom. Some enterprising person, it seems, had "discovered" the powder that was to add so much to the masculine comfort, and his name was to go down to posterity as one of the world's benefactors. The razor manufacturers were warned that their last hour had come. It will be interesting to see how long this magic powder will last in the public estimation. Without analysing it, the conjecture may be hazarded without much fear of error that one of the well-known depilatories enters into composition of the powder, and that its destructive action on the hair is exercised through such instrumentality. If this be so, it may not be long before people will begin to suffer from dermatitis after using the powder, and its use will soon be abandoned in favour of the more tedious method of shaving at present in vogue. In the meantime, the journalists are delighting themselves with the idea that some novel and miraculous find has been made, and doubtless it is wondered how medical men have allowed themselves to be beaten in therapeutic research by some unknown experimenter.

Telephone Sickness. THE advent of every new factor into industrial life brings with it a new train of diseases and disabilities, and though the telephone has been in use now for some years, it has lately increased in popularity so much that it is being worked under conditions of considerable pressure to the operatives. The Post Office having now a system of their own which they started without much practical experience, are beginning to find that the girls employed at the exchanges are liable to a great deal of sickness. This would appear especially to be the case in hot weather, when the constant strain tells on them severely. At the late Conference of Postal and Telegraph Clerks, some ominous facts were brought forward by Miss Mabel Hope, of London, and on them she asked the Conference to pass a resolution demanding an investigation. One of the speakers said that the cases of physical and mental breakdown amounted last summer to the extravagant height of 25 per cent. of the whole staff, and the resolution was passed by the meeting. If the state of affairs pictured be anything like that actually existing, the administration of the telephone system in London must be almost inhuman, and the Postmaster General should address himself vigorously to discovering how the strain on the operators may be reduced.

"Specialists and Immorality." THE Westminster City Council instituted a prosecution last week against a woman who was described as specialist in the cure of corpulency, and also as a *corsetiere*. It was alleged against her that she conducted rooms on the first floor of a building in Oxford Street for improper purposes, and she was aided by two assistants, described respectively as a "dressmaker" and a "cook." The house had been watched by the police, and the character of the visitors noted, and when the evidence was considered sufficient, the prisoners were arrested. We are very glad to see this sign of vigilance and activity with regard to quack "specialists," for it is notorious that the irregular practitioners whom society delights to countenance are in some cases not only swindlers, but criminals of a particularly odious type. Ever since the "massage-establishments" were closed after a long and flourishing career, the evil has cropped up in one form and another. Manicurists and some types of quack "specialists" are not always what they profess to be, and apart from out-of-pocket losses, the innocent patrons of some of these establishments run risks which they would be well-advised to avoid. Quackery, sexual immorality, and abortion-mongering run into each other remarkably easy, and ladies should be careful as to what places they go to for the trimming of their nails and the rouging of their faces.

The Value of a Name. CONSIDERING that the only protection a medical man has against illegitimate imitation is the fact that it is an offence for any unqualified person to describe himself by a title implying that he is on the medical register, it is surprising that many men who take up a special branch of practice prefer to be known by names which confer no such protection, or as to which the protection is doubtful. Ophthalmic surgeons always and properly object to being known as "oculists," which is the designation of the optician, and should not be applied to a medical man. But in other branches of practice the danger of the opposite course is probably not recognised, for some physicians for diseases of women do not object to the more convenient but unprotected title of gynæcologist; physicians for diseases of the skin, to being known as dermatologists, surgeons for diseases of the throat, as laryngologists, and so on. The quack will be alert enough to find out when the public know these terms sufficiently well to expect a qualified man when a gynæcologist, or dermatologist, or laryngologist is mentioned, and then the confusion will be as great as it now is between ophthalmic surgeons and oculists. It is all the more remarkable that this tendency should exist when the veterinary surgeon recognises the value of his designation so well and keeps to it closely, knowing that to be called a "canine specialist" would place him at once on the level of the cat stealer and dog-fancier.

Curative Human Radiations.

The sixth anniversary social evening of the Psycho-Therapeutic Society was held last week at the Bloomsbury Hall, New Oxford Street, and the members congratulated themselves on the progress their organisation has made. Some facts about this curious society are worth noting. The "operators" of the society are without medical qualification except, it is stated, in one instance, but they all possess the "magnetic faculty which no medical training can give." Their object is to "study, investigate, and practise medical hypnotism, suggestive therapeutics, curative human radiations, and drugless healing." No fee is charged except one of five shillings for "clairvoyant diagnosis," but grateful patients frequently give money to the general funds. It is certainly a wise precaution to charge for the clairvoyant diagnosis as so unsubstantial an entity might well be disputed, and when once the five shillings is safe it would be pretty easy to see who was good for further contributions. The list of diseases that have been successfully treated, is almost synonymous with the College of Physicians' nomenclature.

ALCOHOL—A MEDICAL COUNTER-MANIFESTO.

A manifesto with regard to the use of alcohol has lately appeared in a leading medical journal, and has received wide circulation. By reason of the high position in the scientific world held by its signatories, great importance has been attached to the views it expresses. As it appears to us that, both by reason of the wording of the manifesto and of the use to which it has been put, certain misconceptions may arise, we wish to say that we gravely dissent from much of its teaching, nor can we accept it as an authoritative statement of recognised medical opinion on the matter. Without asserting that alcohol has no value in the treatment of disease, we believe that its use is occasional rather than regular, and limited rather than wide. We regard the word "life-preserving" in connection with alcohol as misleading, and we consider the statement that alcohol has "the power to sustain cardiac and nervous energy" rests on no certain clinical or experimental evidence. On the other hand we strongly believe that alcohol is unnecessary as an article of consumption in the case of healthy men and women, and that its general use could be discontinued without detriment to the world's welfare.

Further, believing as we do that alcohol is one of the most fruitful causes of poverty, disease, and crime, we are pleased to add that it is now sparingly employed as a remedy by the majority of medical men.

LEADING ARTICLE.

THE ALCOHOL MANIFESTO.

The recent manifesto on the value of alcohol in diet and in medicine published in the *Lancet* maintains its interest in the public press. The immense mass of correspondence that has flooded the correspondence columns of the lay newspapers emphasises the widespread importance attached to the question thus raised. As might be anticipated in a contentious matter of this kind some writers have not hesitated to impute motives of a somewhat unworthy nature to the issue of a weighty declaration of this kind. That view may be at once dismissed, so far as concerns the gentlemen whose names are appended to the document. Their position is such that it would be impossible to doubt for a single moment the absolute purity and honesty of their motives, as well as those of the medical journal that published the manifesto. At the same time we cannot help feeling some amount of regret that they should have been led to make a formal public statement at this precise juncture, when the chances of drastic temperance legislation are being eagerly discussed. But we cannot so readily absolve the originator of the document until we have an authoritative statement as to his precise position in regard to temperance legislation, to the vested interest in alcohol, and to the medical profession. We are led to this observation because of imputations that have come freely from various quarters. To put the gist of the matter in a few brief words: "Who and what was the author of the declaration? Why did he draw up and issue such a document? Why and under what circumstances did he obtain the eighteen medical signatures?" As the opinions expressed in the manifesto have gone out to the world as an expression of accepted scientific medical opinion, we think that in common fairness the public no less than the medical profession are entitled to a clear and immediate statement upon all the issues involved in the answers to the foregoing questions. In any case it is somewhat difficult to recognise the overwhelming sense of duty that must have influenced the signatories in undertaking so grave a public responsibility, especially when we reflect that their scientific weight is, after all said and done, merely a question of personal guarantee, apart from argument deduced from experimental, statistical and other evidence. As the manifesto has been issued, however, and has attained wide publicity, we have thought it well to obtain an equally authoritative declaration of the scientific medical opinion which declares that alcohol is not a necessity for healthy persons, and has only a strictly limited use in medicine. Dr. Dawson Burns, a well-known authority on temperance matters, has aptly recalled the fact that on at least two previous occasions declarations adverse to the use of alcohol have been issued by medical men. The first of these was issued by a medical man, Mr. Julius Jeffreys, in 1839, and was signed by seventy-eight distinguished members of his profession. It ran:

"An opinion handed down from rude and ignorant times, and imbibed by Englishmen from their youth, has become very general, that the habitual use of some portion of alcoholic drink is beneficial to health, and even necessary to those subjected to habitual labour. Anatomy, physiology, and the experience of all ages and countries when properly examined must satisfy every mind well-informed in medical science that the above opinion is altogether erroneous."

In the year 1847, the following manifesto was drawn up by three medical men, and signed by nearly 2,000 medical practitioners in the United Kingdom:—

"We, the undersigned, are of opinion:—(1) That a very large portion of human misery, including poverty, disease, and crime, is induced by the use of alcoholic or fermented liquors as beverages. (2) That the most perfect health is compatible with total abstinence, from all intoxicating beverages whatever, in the form of ardent spirits, or as wine, beer, ale, porter, cider, &c., &c. (3) That persons accustomed to such drinks may, with perfect safety, discontinue them entirely, either at once, or gradually after a short time. (4) That total and universal abstinence from alcoholic liquors and beverages of all sorts would greatly contribute to the health, the prosperity, the morality, and the happiness of the human race."

Since the two foregoing declarations, a great deal of scientific knowledge has accumulated around the subject. It is to be regretted, therefore, that sixty years after the latter declaration eighteen leading medical men should have been induced to sign another declaration expressing views that are open to grave question alike by the medical profession and by the laity. As things stand at present we agree with the suggestion of some of our readers that it would be well to inform the world that the opinion of many, if not the majority, of the medical profession, is adverse to the habitual use of alcohol either as a medicine or as an article of diet.

CURRENT TOPICS.

Commission on Inebriety.

ONE of the few sensible articles on inebriety and its treatment, we might almost say the only sensible one by a non-medical man we have ever read, was contributed last week to the *Daily Chronicle* by Canon J. W. Horsley. The writer takes a clear and statesmanlike view of the question of the methods of reforming the drunkard, and while not eschewing drug-treatment, he exposes the fallacy of expecting a few weeks' dosage with this, that, or the other medicine to abrogate a moral and physical warp in the constitution. The habitual inebriate, as he shows, is not only a person who suffers from a double dose of original sin, but one whose tissues, especially those of the brain, have degenerated through years of abuse of alcohol, and therefore to restore that person to society in a condition to lead a decently useful life it is necessary not only that his immediate craving should be removed, but that a moral and physical reformation should be brought about as well. To accomplish this result steady pressure of a more than medical kind is necessary, and the inebriate, like the curable mental patient, should be detainable in an institution under healthful influences till the signs of restoration to a condition of responsibility are unmistakable. Canon Horsley dwells on the inefficiency of our present methods, and makes the valuable suggestion that the Government should appoint a Departmental Committee to inquire into the subject. It is a great pity that inebriety was not one of the matters referred to the Royal Commission on the Feeble-Minded, a body eminently fitted to deal with it, but as it was not included in their terms of reference, and as the present reformatory system is egregiously ineffective, it would be a highly beneficial move on the part of the Government if they instituted a separate inquiry. Considering the important questions of restraint and certification involved, the most authoritative form of investigation, namely, a Royal Commission, should be employed.

The "Dairy World" and the Milk Trade.

Our contemporary the *Dairy World* in a leading article last week, rejoices that the new London County Council have dropped the bulk of the milk clauses in their General Powers Bill now before Parliament. Of the advisability of that step we will only say that if these clauses were, as is stated, omitted merely to save the rest of the Bill, the necessity is a highly regrettable one. Happily there is an awakening with regard to milk dangers all over the country at the present moment, and some eighty authorities are seeking extended powers of control of their milk supplies, and we agree with the *Dairy World* that this activity makes out a strong case for national and uniform treatment of the whole subject. The present would be a highly opportune moment for the introduction by the Government of a Pure Milk Bill, but of that we see no sign; it would be a fatal error, therefore, for any local authority to stay its hand in the hope that such an eventuality is likely to occur. But we rub our eyes to see if we are awake when we read in the article referred to such phrases as "we do not recognise the pressing need for further legislation which other people see"; "the present conditions of supply are extremely satisfactory"; and "the metropolis is being supplied with a clean, wholesome article." We have heard it said that it is not possible to avoid gross contamination of milk, but we never heard it said that metropolitan milk was clean. Would the editor of the *Dairy World* allow us to put into his glass a tablespoonful or two of the deposit which can be obtained by centrifugalization of the milk supplied to London? Our idea of a clean fluid is not one containing dung, hair, and detritus, but perhaps surgical and bacteriological training give one exalted ideas of cleanliness.

Cerebro-Spinal Fever in the United Kingdom.

The epidemic of cerebro-spinal fever in various parts of the United Kingdom shows little signs of abating. In Dublin, it is true, the disease has for the time being disappeared, although a few cases still linger in the neighbourhood. In Belfast, on the other hand, the disease is in an active condition: during the week ending April 18th thirty cases of cerebro-spinal meningitis were reported, with twenty deaths from the disease within the same period. The number of cases notified since the commencement of the outbreak has reached the large total of 313, with the high proportion of 200 deaths. Scattered cases continue to be reported from various parts of Scotland. One of the more serious features of the outbreak in that country is the fact that the malady is spreading somewhat widely to the smaller burghs and county districts. One of the assistant medical officers of Glasgow has unfortunately contracted the disease, but is reported to be progressing favourably. During the month 35 cases have been reported in Edinburgh with 24 deaths. In England the epidemic does not appear to be spreading rapidly, but on the other hand it is not losing ground, and the history of previous invasions renders the outlook far from encouraging. Nothwithstanding the abundant opportunity for scientific investigation that has of late been forthcoming little advance has been made in the discovery of practical means of prevention of this disastrous infection.

The Supply of Bodies for Anatomical Teaching.

We are glad to see that the North Dublin Guardians will shortly have an opportunity of re-considering their decision regarding the supply of bodies to the medical schools of Dublin. At their meeting last week, the Guardians had before them two important documents bearing on the matter. One of these was a letter to the Local Government Board from Dr. McWalter, a medical practitioner, himself a Guardian, in which he pointed out the danger likely to be done to patients in a weak state of health by a direct question as to their wishes regarding the disposal of their bodies. The other was a letter from Professor Fraser, on behalf of the Anatomical Committee of the Dublin Medical Schools, drawing the attention of the Guardians to the irreparable injury their recent decision was likely to inflict on medical education in Dublin. The letter was worded in the most moderate terms, and permission was asked to send a deputation to discuss the question with the Board. In the event, notices of motion were handed in with the view of rescinding the resolution of the 17th ult. We trust that the Guardians will adopt a reasonable view of the state of affairs when the matter comes up for decision next week.

Fatal Anæsthesia.

Two deaths under anæsthetics last week in London are worthy of notice. In one case a child died at Guy's Hospital while undergoing an operation, the anæsthetic used being ethyl chloride. The case is of medical interest on account of the rarity of such an occurrence with that particular drug, and also from the age of the patient. In the second case a young baronet died under the influence of a mixture of chloroform and ether. The pathologist of St. Mary's Hospital testified at the subsequent inquest that there was enlargement of the spleen, tonsils, and lymphatic glands generally. This condition had been lately recognised by pathologists as the "status lymphaticus," and its presence indicates a tendency to sudden death. For some time past a similar association has been noted in the case of persistent thymus gland. Obviously, could the actual connection between lymphatic disease and death under anæsthetics be established it might be possible to reduce the number of fatalities from that cause. In any case it may safely be concluded that medical men will be consulted by the "intelligent patient" about to undergo surgical operation as to the presence or otherwise of the "status lymphaticus."

Phosphorous Poisoning.

The attention of the House of Lords was last week called by Lord Lytton to a recent death from necrosis of the jaw due to phosphorus poisoning in a match factory. He laid it down as a definite proposition that every kind of match the public would require might be made without the use of any dangerous form of phosphorus. His reasonable demand was that the United Kingdom should join the Convention of Berne forbidding the use of yellow phosphorus. Six European States,—namely, France, Germany, Italy, Holland, Denmark and Switzerland,—signed the undertaking in question last September. In his reply Lord Beauchamp stated that there had been only five cases of necrosis during five years, and of these cases two were fatal. The Government were of opinion that the special rules had been successful, and in adhering to them they were following the example of six other States represented at the Berne Convention, and also of Norway and Japan. A statement of that kind seems hardly worthy of a country claiming to have at heart the interests of the industrial classes. Five cases in five years of a wholly preventable trade malady like phosphorus necrosis are precisely five cases too many. If it be true, as stated by Lord Lytton, that our Government said they would join the Berne Convention only on the condition that every other country which imported matches should do the same, the assumption of such a position seems hardly compatible with the sturdiness of the national character. In the adoption of Free Trade, for instance, an incomparably larger experiment, the United Kingdom was strong enough to act independently of the whole army of trade interests concerned. Why fight shy of matches?

Proprietary Medicines in America.

There is no doubt that the general practitioner is often at a loss to know what proprietary medicines he may find of legitimate use in his practice. He has neither the time nor the ability to test the value of all the nostrums brought to his notice, and he would be ill repaid it he did so. Bearing such facts in mind, the American Medical Association a year or two ago determined to attempt a differentiation of proprietary drugs of real and legitimate value from those which a self-respecting practitioner had better avoid. The task has been to a certain extent completed and the Association has issued a list of drugs of the former class. No preparation has been admitted without its full formula having been furnished for publication, and no preparation—other than foods and disinfectants—has been admitted which is advertised to the public. Various other conditions have been imposed, and the result is a catalogue which can hardly fail to be of general utility. In its task the Association has naturally been met by violent opposition, not only from the vendors of secret preparations, but from many of the viler medical papers which are at the orders of those who advertise in their columns. It is to be congratulated in bringing its work to a successful issue in spite of this opposition.

The London and Counties Medical Protection Society.

The annual report of the London and Counties Medical Protection Society for the year 1906 points to continued prosperity and usefulness. The work achieved during the twelve months has been manifold and arduous, including as it does a great amount of litigation. The unsatisfactory nature of British law administration is conspicuously shown in an instance referred to by the Chairman, Dr. Heron. It was that of a case in which the Society successfully resisted the claim of a defeated opponent to appeal, yet, notwithstanding the decision in their favour, the action cost the Society out-of-pocket expenses to the extent of £500. One of the best features of this Society is the reserve and guarantee fund, which from all sources amounts to the very respectable sum of £9,000. Another important point emphasised by the Chairman, Dr. Heron, was the desirability of an arbitration clause being inserted into all partnership agreements between medical men.

PERSONAL.

The English medical man in attendance upon the Queen of Spain during her forthcoming confinement is Dr. Glendening.

A new Russo-German Medical Society has been constituted in Berlin under the presidency of Professors Von Leyden and Hildebrand, of that town, and Professor Bechterew, of St. Petersburg.

Mr. Richard Macartney, L.R.C.S.&P. Edinburgh, of Cinderford, was recently appointed Coroner for the Forest of Dean District at a meeting of the Gloucestershire County Council.

Dr. Barclay Smith is to be appointed to examine in human anatomy for medical degrees for the remainder of the year ending November 1, in the place of Dr. A. Macalister, who is unable to examine.

Dr. Archibald, Assistant Medical Officer of Health for Glasgow, who has himself fallen a victim to spotted fever, is progressing favourably.

The Royal Commission on Vivisection held their seventeenth meeting on April 22nd, Viscount Selby presiding. Sir T. Lauder Brunton gave evidence.

Sir William J. Collins, M.P., M.D., will take the chair at the New Reform Club on May 10th, when an address on "The Necessity for a Minister of Public Health" will be delivered by Mr. A. Rolland Rainy, M.P.

Dr. P. H. H. Pereira has been selected for the office of Assistant Port Health Officer, Medical Department, Singapore, and is to act for the present as Deputy Health Officer at Penang.

Dr. James Ritchie, who has held the appointment of professor and reader in pathology at Oxford for the last six years, has accepted the position of superintendent of pathological laboratories in connection with the Royal College of Physicians at Edinburgh University. Dr. E. W. A. Walker, Fellow of University College, has been appointed deputy until Mr. Ritchie's successor is appointed.

A CLINICAL LECTURE

ON

GLAUCOMA. (a)

By ARTHUR HY. BENSON, M.A., M.B.Dub., F.R.C.S.,

Surgeon to the Royal Victoria Eye and Ear Hospital, Dublin; Ophthalmic and Aural Surgeon to the Royal City of Dublin Hospital.

Gentlemen,—The subject which we have to consider to-day is one of the most important in our whole list. Glaucoma, the many-headed hydra of ophthalmology, presents itself in numerous forms, differing widely in almost every particular except one, viz., the increased tension of the eye. This, then, is the cord that binds together all the various conditions which are grouped under the one heading as glaucoma.

If we seek to frame a definition of glaucoma, it is not at all easy, and most writers are content to describe the condition without defining it. Priestley Smith has, however, defined it as "An excess of pressure within the eye, plus the causes and the consequences of that excess." High tension is only a symptom, but it is such an important symptom that one is in danger of regarding it as the disease itself; but the causes and the consequences of the high tension are necessary to the full definition of the disease.

It is impossible in one short lecture like this to do more than lightly touch upon a few out of the many important points which present themselves for consideration.

Classification of Glaucoma.

Glaucoma is commonly divided into two great divisions:—

I.—*Primary Glaucoma*, where no obvious cause for the condition is discernible. This is subdivided into (1) Acute, where the attack is sudden, intense, and painful, with vascularity and rapid loss of vision. (2) Sub-acute, where symtoms are much less severe and where pain is not constant. (3) Chronic, where there are no signs of inflammation, no pain, and the loss of vision is very gradual.

II.—*Secondary Glaucoma*, where the high tension is obviously the result of some previous pathological condition, such as an intra-ocular tumour, iritis (which was followed by adhesions between iris and lens, or iris and cornea), or swelling or dislocation of the lens, &c. It is primary glaucoma that we are to-day considering.

Ophthalmoscopic Appearances.

The hazy "ground glass" appearance of the cornea, the shallow anterior chamber, the dilated and sluggish pupil, the opalescent (or, at times, greenish) look of the pupil (which may easily mislead a careless observer to diagnose cataract), and, in acute glaucoma, the general vascularity, and, in old chronic glaucoma the large dilated varicose veins on the sclerotic, all these can be easily seen with the naked eye.

With the ophthalmoscope you can usually in chronic glaucoma observe an excavation of the disc, which, from the intra-ocular tension, is depressed below the surface of the surrounding retina, and is also paler in colour (at times having a dull greenish gloomy look that is very characteristic). Over the edge of the depressed or cupped disc the vessels of the retina seem to tumble with a suddenness that shows the steepness of the sides of the depression.

Three kinds of cupping of the disc are commonly recognised: (1) The physiological cup, which is V-shaped, and never occupies the whole surface of the disc; (2) the atrophic cup, which is shallow and more like a saucer than a cup; and (3) the glaucomatous cup, which always occupies the whole of the disc, is deep, and has steep sides over the edges of which the vessels disappear abruptly. In acute glaucoma the disc is often not cupped, as there has not been sufficient time for the change to take place.

Intra-ocular Secretion.

The globe of the eye is mostly filled with liquid or semi-liquid transparent fluids—the aqueous and the vitreous. In these the lens and the iris are suspended, and are more or less movable. These fluids allow the rays of light that enter the eye to pass through them to the retina, they preserve the globular shape of the eye, they keep the retina and chorioid pressed against each other and against the sclerotic (the strong fibrous capsule of the eye), and they regulate the pressure that is constantly exercised upon the blood-vessels within the globe.

The great secreting organ within the eye is the ciliary body, which may be regarded as a muscle and a gland combined. It (with some assistance from the iris) secretes the aqueous and the fluid of the vitreous, it nourishes the lens which (after fœtal life) is entirely without blood supply of its own, and by keeping up a flow of nutrient fluid, maintains the tension of the eye at an almost constant degree. If the ciliary body is irritated its secreting function may increase, and for the time it may pour more than the normal amount of fluid into the globe, and the tension will rise. If the irritation goes on to true inflammation, the secreting power of the ciliary body diminishes, the fluid it pours into the eye is scanty in amount and defective in quality, and you get a low tension with subsequent defects of nutrition evidenced by opacitus in the vitreous and lens, and often on the posterior surface of the cornea, with muddiness of the aqueous and all the conditions that terminate in phthisis bulbi.

The fluids secreted by the ciliary body, having flowed through and nourished the vitreous, escape from the eye in part by the lymph spaces about the optic nerve. Most of the fluid, however, percolates through the suspensory ligament of the lens, and, joining with the iritic secretion in the posterior aqueous chamber, passes through the pupil into the anterior chamber, and escapes from the eye at the angle of the anterior chamber, where the iris and the cornea meet. The very minute spaces of Fontana in that situation permit the passage of the aqueous from the eye into the canal of Schlemm (a circular sinus in the sclerotic), which is in direct connection with the veins of the general circulation.

(a) Delivered at the Royal Victoria Eye and Ear Hospital, Dublin.

If the ciliary body secretes the normal amount of fluid, and if the filtration spaces allow the normal amount to escape the tension of the eye remains a constant.

If the ciliary body secretes too much, or if the filtration spaces excrete too little, the tension rises just as the water in a river will rise if there is too much rain, making a flood, or if a dam is built across the river producing an obstruction to the normal outflow.

In the eye the commonest cause of high tension is not the "flood" but the "dam." It is not usually hyper-secretion, but defective excretion that causes the glaucomatous condition.

POSITION OF OBSTRUCTION.

There are three places within the eye where this damming back of the stream may take place—(1) The narrow space between the margin of the lens and the ciliary body, occupied by the suspensory ligament of the lens; this "peri-lenticular space" is considered by Priestley Smith to play a very important part in the production of primary glaucoma. (2) The pupil is the next tight place through which the fluid has to pass on its way to the canal of Schlemm. Here, under normal circumstances, the iris though touching, is not adherent to, the anterior capsule of the lens; it can be easily moved, and so allow the fluid to pass into the anterior chamber. If, however, there has been iritis, and the iris and lens are stuck together with lymph (synæchia posterior), then the iris cannot be separated from the lens capsule, and the fluid in the posterior aqueous chamber cannot pass into the anterior chamber, and again a high tension may occur. High tension so produced is called "secondary glaucoma," because it is due to some obvious cause, viz., the iritic adhesions. (3) The third and most important place where a dam may be formed is at the angle of the anterior chamber itself. The root of the iris may be pressed against the cornea, and thus the percolation spaces may be obliterated and the aqueous after successfully negotiating the peri-lenticular space and passing through the pupil, may find its passage barred by the iritic angle.

TREATMENT.

In a large majority of cases of primary glaucoma it is the angle of the anterior chamber that is at fault, and treatment has to be directed mainly in that direction.

In secondary glaucoma, the indications for treatment vary according to the cause. If iritic adhesions are the cause, an iridectomy will cure it; if a swollen traumatic cataract is the cause, the lens must be removed, and so on.

In primary glaucoma, blocking of the angle of the anterior chamber (the "iritic angle") is the direct cause of the high tension; and treatment must be adopted whose object is either to re-open the normal percolation spaces, or obtain abnormal filtration of the intra-ocular fluids through the coats of the eye.

Until a comparatively short time ago, no cure had been discovered for this disease, and every case of glaucoma was morally certain to go blind. Thanks to the genius of Von Græffe and others, the disease is now capable, under early and skilled treatment, of most satisfactory and successful cure.

Myotics, *i.e.*, drugs that contract the pupil, such as Eserin and Pilocarpin, when instilled into the eye (1 per cent. solution), help to put the iris on the stretch, so that there is less of it tending to fill up the angle of the anterior chamber. The aqueous is thus more easily able to escape through the spaces of Fontana into the canal of Schlemm. A myotic is, in some few cases, sufficient by itself to re-establish the balance between secretion and absorption, and the tension may become normal, at least, for a time.

In most cases, though myotics reduce the high tension, they do not cure the disease, and operation is required.

Iridectomy is the operation that suits a vast majority of cases of glaucoma, but in certain instances sclerotomy, either anterior or posterior, is preferable. My advice to you is in every case of increased tension that comes under your care, at once use eserin or pilocarpin, stop all use of the eyes, and if the tension does not very soon subside, either do an iridectomy yourself, or send the case up *without delay* to a specialist. It is fatal to keep watching a case of glaucoma from day to day and week to week, before making up your mind to have the case treated properly.

In *acute* glaucoma, not only every day, but every hour of delay means irreparable injury to the sight, and I cannot insist too strongly upon the necessity—the absolute necessity—of *immediate* treatment.

Acute glaucoma often comes on so suddenly, with violent neuralgia-like pains in head, and vomiting, that it is mistaken for acute biliousness, and precious time is lost in giving antibilious medicine, instead of at once attacking the *fons et origo mali*, the high intra-ocular tension.

In these cases of acute glaucoma, the conjunctiva becomes congested, the cornea becomes hazy, like ground glass, the pupil dilated, and the anterior chamber shallow. Such cases are often mistaken for iritis, and are treated with atropin—a fatal error, for atropin by still further dilating the pupil crowds up the angle of the anterior chamber and increases the difficulty of the outflow of fluids from the interior of the eye.

Never use atropin in any case without feeling the tension and assuring yourself that it is normal.

FIELD OF VISION.

The field of vision, (*i.e.*, all that one can see, in addition to the object looked at, without movement of the eye) is always much contracted in advanced glaucoma, and by careful testing of the field the earliest sign of the advancing disease may often be obtained; but to test the field accurately, and to detect slight changes, requires some skill and the use of a special instrument, called a Perimeter.

In an advanced case, it is easy to recognise the defect if you get the patient (seated about two feet away from you with one eye covered) to look at your eye. Then move a very small piece of white paper, attached to the end of a pen-handle, about half-way between your eye and your patient's eye. You will be able, while you look at his eye and he looks at yours, to see the piece of paper moving about.

If your patient is not able to see it as far out to the periphery as you are, it indicates (other things being equal) a defect in his field.

In this test, in order to compare his field and yours, you should only keep open the eye the patient is looking at. If you are testing his left eye, he should look at your right eye, and you should keep your left eye shut.

Prognosis.

The prognosis depends to a large extent upon the length of time the disease has lasted, and its severity. Acute glaucoma can almost always be cured by *prompt* treatment, but every hour is of vital importance.

Chronic glaucoma, also, can usually be cured, if taken in good time, but its onset is often so insidious that it is not detected by patient or medical attendant till it is fairly far advanced.

The sooner any case of glaucoma is placed under proper treatment the better the prognosis.

Warnings.

Never use atropin in elderly people without good reason, and watch the tension all the time they are using the drug.

In all cases of iritis, or irido-cyclitis, feel the tension before ordering atropin to be used, and also after using it.

In all cases of "bilious vomiting," feel the tension, for acute glaucoma often simulates a bilious attack.

In all cases of failing sight, with or without cataract, examine the tension carefully, for chronic glaucoma often simulates senile cataract and may easily be mistaken for it.

In all cases of increased tension immediate treatment is urgent, and should not be delayed.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by John Poland, F.R.C.S., Eng., Senior Surgeon to the City Orthopædic Hospital, London. Senior Surgeon to the Miller Hospital, Greenwich. Subject: "The Use and Abuse of Skiagraphy in Fractures and Dislocations," lecture delivered at the Medical Graduates College and Polyclinic.*

ORIGINAL PAPERS.

CEREBRO-SPINAL MENINGITIS; ITS RELATION TO OTHER FORMS OF MENINGITIS. (a)

By W. B. WARRINGTON, M.D., F.R.C.P.Lond.,

Physician to the David Lewis Northern Hospital, Examiner in Clinical Medicine and Lecturer in the University of Liverpool.

Robert Whytt, in 1786, is said to have been the first who accurately recognised the clinical picture of tuberculous meningitis, and Papovoine, in 1830, showed its real nature. In a recent leader in the *British Medical Journal* it is stated that the first recognition of an epidemic of meningitis was in Geneva in 1805. Since then the independence of these two diseases has been clearly recognised. But it is only since the rise of bacteriology that the ætiology and symptomology of the forms of meningitis have been precisely studied. All cases of acute meningitis are cerebro-spinal in their distribution, but the term "cerebro-spinal meningitis" is now accepted to mean that form of disease caused by a specific micro-organism, viz., the diplococcus intra-cellularis meningitidis, first described by Weischelbaum in 1887. Sporadic cases of meningitis caused by this organism are always present in any large city, and their clinical, anatomical, and ætiological features, as met with in children, were first clearly described by Lees, Barlow, and Still, whose classical article is in Clifford Allbutt's system. These writers gave the name of "Posterior Basic Meningitis" to the disease; but on the Continent and in America it is referred to as the sporadic form of cerebro-spinal meningitis. Of 38 cases of meningitis seen by me in the last five years, I find 17 were tuberculous, including two adults, nine pneumococcal, of which one was primary; in three there were pneumonia only, in two endo and pericarditis, and in one the primary source was the ear. Another occurred in a child with broncho-pneumonia, and another in an adult with aspiration pneumonia secondary to carcinoma of the æsophagus. Four were due to the streptococcus, in two the ear being the primary site; the other two due to injury. One case was staphylococcal, and in six cases the meningococcus was the cause of the disease. Two of these cases recovered, one of whom was an adult.

All evidence goes to show that when meningitis affects a large number of people at the same time, its cause is meningococcus. Many recent observations are given in the leader referred to in the *British Medical Journal* from epidemics in New York, Syracuse, Portugal, Lisbon, and Glasgow. The important points for consideration are: (1) Are the epidemic and sporadic forms identical; (2) the characteristics and life history of the organism; (3) the mode of contagion; (4) the recognition of the disease during life; and (5) its morbid anatomy.

With regard to the identity of the two diseases, I have said that Continental and American observers consider them to be the same. The organism, described by Still, in the Great Ormond Street cases, and that since found in other sporadic cases, agrees in all essential particulars with the meningo-coccus found in epidemics. My case of a man, æt. 25, would, had it occurred now, have certainly been notified as cerebro-spinal meningitis. Its fulminant onset, violent symptoms, the positive findings from the examination of the cerebro-spinal fluid, and its termination in recovery precluded any other causal agent for the meningitis.

A number of facts about the organism and its history are now known. It is a biscuit-shaped diplococcus, and whilst, in the early days of the illness, is often found to be intra-cellular, it is also found, especially at a later period, existing free in the cerebro-spinal fluid. It stains readily with ordinary dyes, but has the important characteristic of failing to stain by Gram's method. It is not an easy organism to cultivate, the best medium being nutrose acitic agar, called nasgar. It also grows well in a mixture of one part of acitic fluid and 10 of broth, and can be cultivated on blood agar. These media should, therefore, be used when a positive diagnosis is required from the examination of the cerebro-spinal fluid. It is important to note that the growth of the organism is arrested at temperatures above 42 deg. or below 25 deg. C. The organism is found in the pus of the meninges of the brain and cord, but not infrequently it is also found in the blood, causing a septicæmia. In one of the New York epidemics this was found to be the case in 25 per cent. of 130 cases, and in the remarkable case described by Andrews, a fatal case of purpura was found to be due to meningococcal septicæmia, although there was no evidence of meningitis. The organism does not live as a saphrophite outside the body, and in healthy persons in non-epidemic times observers have failed to find this organism in any of the secretions. In the naso-pharynx of those who come in contact with the sick the organism is not infrequently found, and attention must especially be directed to the upper part of the passages and posterior nares. Lingelsheim found the organism in 24 out of 346 healthy persons who were in contact with the sick, and Ostermann demonstrated its presence in no less than 17 out of 24 persons belonging to families, some of whose members were sick with the disease.

Mary Goodwin and Anna Shelley have recently shown that the organism may be found in 50 per cent. of the naso-pharynx in those suffering from meningitis, and in 10 per cent. of those who come in contact with the disease. Conjunctivitis is sometimes one of the complications, and Canby Robinson reports the presence of the organism in the pus from this source. It is, therefore, obvious that these secretions may become foci from which an epidemic may start. Dr. Blynn met with one epidemic in which all the children affected attended the same school. House epidemics have been recorded. Sanitary conditions are of great importance. In the United States ship Minneapolis, whose normal complement of 500 men was increased to 1,450, 26 were affected, and all from the main deck, which was especially overcrowded and lacking in ventilation. The soil on which the organism is engrafted is important. Cerebro-spinal meningitis and infantile palsy have much in common. They both are due to infective processes, both have their maximum incidence during certain months of the year, and when epidemic both may occur together, and both diseases can be met with in the same person.

(a) Read before the Liverpool Medical Institute, March 7th, 1907.

An unusual number of cases of Landry's paralysis have also been met with during epidemic times, and it is worth noting that the pathogenic organism obtained from this case by Farquhar Buzzard was a non-Gram staining tetracoccus. A similar example has also been obtained from another example of Landry's paralysis, and Risien Russell considered the organism he found in a case of meningo myelitis as similar to that isolated by Still in the posterior basic cases. The epidemic itself shows certain peculiarities. It prevails severely in widely separated areas, but it does not spread widely, it never becomes a pandemic. Its mortality ranks among epidemic diseases next to the plague. In the last two years in New York 3,000 out of 4,000 persons attacked, died.

With regard to the morbid anatomy the sporadic cases certainly present a picture on the autopsy table, differing sharply from those forms of meningitis due to the tubercle bacillus, the pneumonoccus, and other pyogenic organisms. The lesions of the tuberculous and other forms are well known. In the sporadic cases a striking feature is the collection of fluid, either clear or purulent, in the posterior arachnoid cistern—a sac formed by the two layers of the pia-arachnoid, and limited in its external boundary by the further attachment of this membrane to certain parts of the brain. The sac extends as far forwards as the inner and anterior margin of the temporo sphenoidal lobe, and from there passes over the optic chimasa, interpeduncular space, and anterior surface of the pons. Posteriorly the great basal space thus formed passes round the medulla, limited behind where the arachnoid becomes again attached to the pia on the under surface of the cerebellum. It is the accumulation of inflammatory products in this great cistern which has suggested the name of posterior basic meningitis. The inflammation is, however, not limited to these regions, extending to a slight extent on to the lateral surface of the hemispheres. The pneumococcal meningitis, on the other hand, is distinguished by the vertical distribution of thick, characteristic, greenish pus, and in those streptococcal forms which I have seen taking origin from ear disease, though the posterior cistern contains a good deal of fluid, the inflammation was much more visible over the upper surface of the brain than in the posterior basic forms. Now, in the epidemic forms the published accounts show that there is much wider distribution of the inflammation than in the sporadic cases, yet its maximum intensity falls on the posterior aspect of the brain. This appears to be the rule, but in some cases the exudate is however quite as marked over the sides and vertex of the brain. The cord is more affected than in other forms of meningitis—a thick band of purulent material may be found in the pial meshes down its whole length. I have, however, seen this feature well shown in a pneumococcal case. The naked eye appearances, therefore, are not so characteristic in the sporadic as in the epidemic cases. Amongst associated lesions broncho-pneumonia and collapse are not infrequent. A true croupus pneumonia is, in the epidemic as in the sporadic cases, uncommon, thus contrasting markedly with the findings in pneumoncoccal meningitis. Hydrocephalus is, as well known, one of the occasional sequela of the sporadic and epidemic forms, and it is not unlikely that the true cause of this is an inflammation of the ependyma which lines the ventricles. The curious form of amaurosis usually ending in recovery, and the permanent deafness due to inflammation of the labyrinth, are met with in both forms.

Briefly, comparing the symptomology of the epidemic and sporadic types they agree in essential particulars. In no other form of meningitis is the head retraction and tonic spasms of the back muscles so well marked. In both the onset is sudden in contrast with the more common forms of tuberculous meningitis. In both temporary amelioration may take place, and in both the convalescence is long and tedious. The points in which the epidemic seems to differ from the sporadic type are (1) greater virulence. Speaking to the students of the Edinburgh University last month, Professor Osler said: "We know of no disease which can strike patients with such lightning-like rapidity, in so fulminant a manner, as cerebro-spinal fever. There are instances in which death has occurred within six or eight hours. A few years ago in Washington I saw a robust, healthy man, who had left his house immediately after luncheon, and who, as he was stepping out of a tramcar at about 2.30 p.m., had a sudden pain at the back of his head. I saw him that night at ten o'clock; he was in a condition of extreme prostration and high fever, violent delirium, with a temperature of 104. At three o'clock in the morning he was dead." It should not be forgotten, however, that pneumococcal meningetic may in children be most rapidly fatal.

(2) The presence of skin eruptions, notably herpes, which is frequent, purpura, which, in the present cases in Britain is rare, and generally of erythema. (3) The septicæmia indicated by the typhoid state and large spleen. (4) The age of the patient. The majority of cases in the sporadic type are under one year old; the epidemic attacks all ages. At the bedside in diagnosis the two questions are: (1) Is the disease meningitis, and (2) if so, what is its nature?

The first question is, of course, one often confronting us. The fevers, influenza, and otitis media may show cerebral symptoms without meningitis being present. Whether the case is really one of meningitis or not can only be answered by a knowledge of general medicine, aided by the findings of lumbar puncture. The latter procedure will also show with what form of meningitis we are dealing. It appears quite certain that if, in a person suspected to be suffering from meningitis, the cerebro-spinal fluid withdrawn by lumbar puncture, shows the presence of a considerable number of cells, the case is one of meningitis. The method is easy of performance in children, and in those in a semi-comatose state; but if there is much spasm of the back muscles, it may be very difficult without an anæsthetic. After the fluid is obtained it should be carefully centrifugalised, and the deposit extracted by a capillary tube. Under the microscope attention must be directed to the kind of cells present, and also to the existence of micro-organisms. I have made this examination in a large number of cases, and find it most reliable. In the tuberculous forms, the cells are of the lymphocytic type—small and mononuclear. The bacillus may be not infrequently obtained after careful centrifugalisation. In all other forms of meningitis the cells are, on the contrary, large and multinuclear, except in long standing cases of cerebro-spinal meningitis where lymphocytes appear in considerable numbers. The pneumococcus and other pyogenic organisms can usually be recognised and identified. The meningococcus, however, may, if lumbar puncture has not been done early in the disease, be difficult to find. If a suspicious organism is found a positive report may be given after careful bacteriological examination. Even, however, if the organism is not found, the true nature of the case may be discerned by considering the clinical history, duration of the disease, and the absence in the cerebro-spinal fluid of the pyogenic organisms, commonly found, together with the presence of multinuclear leucocytes.

Treatment.—Grave as this form of disease is, it is the only form of meningitis in which we are not compelled to give a practically hopeless prognosis; 30 per cent. to 40 per cent. of cases recover. Flexner is endeavouring with some success to obtain an anti-serum. Until such a product is obtainable, we can only rely upon opium and hot baths to relieve the pain and suffering, and if followed by relief, repeated lumbar punctures should certainly be done. In cases which become chronic emaciation is often very marked, and the greatest care should be taken in feeding. Prophylaxis is, of course, the most important, and the methods to be adopted will be gathered from what has been said in the earlier part of this paper.

There is no doubt that sick persons should be isolated, though the direct contagion of the disease from person to person is probably no greater than in pneumonia. The secretions must be disinfected, and it would be well if those engaged in nursing would use antiseptic lotions to the naso-pharynx, bearing in mind that it is especially in the upper part of this passage that the organism has its dwelling-place.

ON THE PRESENT POSITION OF THE TREATMENT OF TUBERCULOSIS BY MARINE CLIMATES. (a)

By WILLIAM EWART, M.D.Cantab., F.R.C.P.

Senior Physician to St. George's Hospital and to the Belgrave Hospital for Children.

PART II.

In estimating the results obtained at the seaside and elsewhere, the precision of the mathematical method is illusive. It is wasted upon a clinical material ill-suited for statistics, with its features of latency at the beginning, of continued uncertainty as to the type and severity of the disease, and of precariousness at the later stages. Greater reliance can be placed upon experienced clinical observations and upon some of those great simple facts which, like the face of the sun, are rarely looked at. The first group—that of *threatened*, or of the earliest demonstrable, tuberculosis—furnishes the best results of marine treatment. The second, that of *tuberculosis in progress*, is difficult, anxious, and uncertain. The pyrexia may stop. Who knows that this was not automatic, given the individual and his lesions? Or it may last interminably, and who will say that the given lung and the given strain of bacillus could have behaved any better inland, or on the heights? The truth may be revealed to the acute perceptions of the clinician, but there can be no strict proof. Inference, however, does suggest that any conditions which are demonstrably favourable in the stage of confirmed phthisis are likely to be those best suited to its stage of progress. This brings us to the consideration of the *advanced cases*.

This third group provides us with much more definite tests for climates. Any climate which could effectively protect life, and preserve the survivors for indefinite periods, would become a sort of clinical museum of these rare specimens. Is that clinical display one of the features of our seaside resorts? If not, is this due to the cures effected being so substantial as to render unnecessary a permanent residence at the sea? At Davos the acknowledged prolongation of life in phthisis is attested by an unique and ever-growing popularity. It is traceable to two circumstances—the utmost protection against secondary infections, and the absence or brief duration of any ordinary catarrhs owing to the purity and the glacial dryness of the air in winter, and to its stillness. Healing lungs are safe so long as bright weather or dry frosts prevail. At the same time, it is remarkable how well the change of season is borne even by much excavated lungs provided they are not exposed to influenzal infection.

A favourable predisposition doubtless helps to explain the immunity of those well-seasoned survivors. But there are less fortunate subjects whom an excessive liability to catarrh unfits for the benefits of the Alpine winter. The cold is too intense an irritant for their sensitive mucous membrane. These are precisely the subjects whose catarrh does not heal at the coast, and whose only chance of a temporary lull in its encroachments lies in the protection afforded by warmer winter stations. These patients appear to form a smaller minority at Davos than at our marine resorts. These facts point a lesson in the management of those less advanced cases whose tendencies are not fully declared. It is of supreme importance that they should be allowed if possible the highest rather than any lower degree of safeguard against the risks of catarrh; and for them the altitude *cæteris paribus* seems to offer the best chance and the quickest method of recovery. However, as the masses who are chiefly concerned cannot avail themselves of the altitude, our attention must be confined to our own valuable marine climates.

The Aerotherapeutic Factors of Sea-Air in Pulmonary Tuberculosis and Catarrh.

In our treatment of tuberculosis, it is not the open-air that kills the bacillus, safely sheltered in the depth of air-tight tissues. The "airing" is for the man, not for his microbe. But sea-air can reach the respiratory surface and influence its condition, and it is credited with the following activities:—(1) *The Tonic action* is both local and general. It strengthens the membrane by direct contact, and every tissue and function by raising the cardio-vascular tone. (2) *The Cutaneous action* is exercised upon the epithelial, the glandular, the vascular, the muscular, and the nervous elements of the skin, and in virtue of the close nervous and vasomotor sympathy of the skin with the respiratory mucous membrane it is capable of strong reflex effects upon the latter. *The Respiratory or Inhalation action* is dependent upon any undescribed volatile properties of the atmosphere, but mainly upon its salt, its moisture, and its temperature. At Mont Dore ordinary catarrhs are cured by inhalations of steam mixed with pulverised saline water. Any stray cases of "latent" tubercle, if improved thereby, must be regarded as having benefited in spite, rather than because, of that combination. The heat and moisture must favour the growth of bacilli, and their dissemination in the tubes by hydrating the mucus. From these risks the inhalation of sea-air is free. It is true that the air is never dry nor glacial; but it is sufficiently cool in winter, and the salt may act as a corrective for the moisture. The "salting" of the mucous membrane is effected partly by suspended crystalline particles, and partly by concentrated droplets in which the saline solution approaches to saturation, and is therefore desiccating. This high degree of concentration is a dehydrating factor to set against the effect of damp air. As a paradox I might speak of this as "dehydration in the wet way." We are familiar with the effect of "brine" upon animal tissues; the healing effect of sea air upon common catarrh and upon bronchial delicacy probably belongs to the same kind of action. This dredging with dry salt and this spraying with brine are of an infinitesimal order, but they are continuous, whereas the much more powerful artificial treatment in the inhalation room is of brief duration.

Sea-Fog.—Special attention may be claimed for this subject in the debate. The common sea-fog is analogous to the Mont Dore inhalation, with the difference that the vapour is a cold one; it cannot be regarded as an essential, nor perhaps as a desirable phase of the sea-air treatment of pulmonary tuberculosis; but it may be of less serious detriment than is commonly thought. I have known recovery take place from extensive caseation and catarrh in spite of continued exposure to its prevalence.

(a) Opening Address to the Debate at the Hastings Meeting of the Balneological and Climatological Society on March 16th, 1907.

Among the *exhalations*, a distinction may be made between those of the sea itself and those from the shore, where animal and vegetable matter is always undergoing decomposition. It is here that iodine is likely to be liberated in large quantities, together with other odoriferous and perhaps stimulating effluvia, in addition to any other volatile organic contents in the pure air blown from the sea. A practical question arises in connection with these seashore exhalations. An opinion is said to have been expressed by Walshe, and has been endorsed by Dr. A. Ransome (*a*), to the effect that the actual seashore is bad for phthisis. Dr. Wm. Gordon informs me that "he has known of cases of obstinate hæmoptysis in *sea-front* lodgings close to the water, lose their hæmoptysis when sent a short distance (about a quarter of a mile or less) further from the sea." This is a serious indictment against the reputation of the beach well deserving of elucidation in our discussion.

The Meteorological Factors in the Aerotherapeutics at the Seaside compared with those at the Altitude.

The winter climate of Davos is famed for its stillness, clearness, powerful sunshine, and pure, cold, dry, rarefied air, which affords little conduction for heat or electricity, and is highly ozonised and, according to Jessen's recent estimations, also highly radioactive. With the exception of our sunshine which is tempered by a thicker atmosphere, and of our sea ozone, it might be said that the contrast presented by our seaside climate was almost absolute. At the coast, atmospheric pressure is at its maximum, as well as the density of air, its moisture, and its conductivity for heat and electricity. We might have expected even greater divergencies than are observed in the results. As a fact, the chief difference in the latter is one of degree. Nature, ever adaptive, has supplied some elements of compensation which tend to restore the balance.

At the sea, general metabolism is stimulated by cutaneous stimuli, through loss of heat and of electricity instead of through their conservation; and catarrhs are benefited by sea-air because of its salt and in spite of its moisture. A stimulation of the respiration forms part of this all-round stimulation, and is more specially connected with the increased muscular activity called forth by loss of heat. But there is nothing analogous to the considerable gain in thoracic diameter induced by the automatically increased respiratory labour in the rarefied air. The Alpine "Liege-kur," whilst resting the lung and the heart from all strain of bodily exertion and of cough, involves in reality a good deal of unconscious respiratory exercise. This perpetual cardio-respiratory work and blood aeration without any general exercise or muscular wear and tear, are a speciality of the altitude. At the seaside any increase in respiratory function is dependent upon muscular work, and in response to the more chilling cutaneous stimuli; and, bodily exercise being directly called for, the conditions for the pulmonary rest-cure are less favourable, and the complications of biliousness and hepatic congestion, which are quite exceptional at the altitude as a result from immobilisation, are much more likely to occur.

The Suitability and Selection of Marine Climates.

The task of selection for purposes of cure is more responsible than that for mere *Euthanasia*. The safety, comfort, and cheerfulness of our best protected seaside resorts might spare many enfeebled sufferers the fatigue of distant travel, which others so keenly desire. There are two criteria of personal fitness for a moderately bracing sea-side climate—good power of "reaction," which is primarily a nervous and vasomotor question; and a good cardio-pulmonary adequacy, which is primarily a question of the extent of the lung surface available, and of the amount of work to be permitted to fall upon it and upon the heart in the particular case. The heart, it goes without saying, must be able to back the effort at pulmonary repair. Any doubt as to this double endowment must point to the need for a protecting rather than a stimulating station.

The Importance of the Cardio-pulmonary Factor is well displayed in the cases of "surgical tuberculosis." The integrity of their respiratory function is their efficient weapon against the infection. But where the lung itself is the seat of the disease, its safety becomes the first consideration, and this forbids the respiratory risks attendant upon the stronger climatic treatment. Should, however, the lung lesion be strictly limited and without associated catarrhal tendency as in the "latent" cases, then it may be possible, with the help of the same test, to conciliate these opposing ends. The less relaxing stations may be the best for them, as moderate exercise may be allowed; and the same may apply to some cases of healed or arrested phthisis.

The following definite statements may now be put forward:—

1. In regard to tuberculosis *other than pulmonary*, the present position of the marine treatment is quite sound, but its advantages are still imperfectly utilised.

2. *Pulmonary Tuberculosis* is the difficulty. Sea-air will not cure bad cases that inland air cannot cure. But sea-air is specially fitted to cure the liability to tuberculosis. Its powers in prevention have hardly been fully turned to account.

3. In connection with the modern ideas of treatment in pulmonary phthisis the sea-side has been at a disadvantage in two directions: (*a*) It possesses *no germicidal* virtues comparable to those aimed at by bacteriological methods; (*b*) *The Rest-cure*, which is the unchallenged doctrine of the day is not its special strong point; on the contrary, muscular exercise is the soul of marine climatic treatment.

4. Both these objections are believed to be temporary; and, when they have ceased to be applicable, a greater future will be opened up to the sea-coast for the efficient treatment of phthisis.

5. Meanwhile our policy must be opportunist; and as we have not any altitudes to choose from we should make the most of our seaside advantages, by selection, by protection, and by local improvement. Climatic seaside treatment is of great value not only in the large categories of surgical tuberculosis and of scrofula, but also in the ill-defined but important group of "latent," or early, "local" tuberculosis of the lung, in which the necessity for the lung rest-cure cannot be so strongly urged. Those subjects who are merely threatened, being still in possession of their pulmonary adequacy, may be sent to the more bracing stations such as those suited for the scrofulous and for surgical tuberculosis. But where the presence of a bacillary lesion can be made out, the choice must be adapted to the condition, with every safeguard against catarrh or over exertion.

6. *In declared early phthisis* the same applies yet more stringently. But here climate, even of the best, does not suffice. Treatment is required which shall be planned on the Hospital idea combined with the Sanatorium idea. For the present, until the bacillus is no longer invincible and until the rest-cure ceases to be a moral obligation, much might be gained by improved methods of protection against undue asperities of climate, so that, for instance, bracing air might be available without the complicating evil of wind.

7. Lastly, *advanced phthisis* is an unprofitable field. As there is little promise in treatment, the highest degree of climatic protection is the main indication. And that is also the requirement for the select few who survive the long ordeal of phthisis. For them, and for those still fighting a hard but not yet hopeless struggle, our marine climates are imperfectly adapted and may not ever be capable of competing with the altitude.

(*a*) "Treatment of Phthisis," page 133.

The "Present Position."

The present stage is to be viewed as one of evolution. The great resources which our sea-coast affords are still undeveloped because two great facts before us have not yet been pressed upon us with compelling force. Nature has supplied decimating diseases for purposes of her own, and although she may offer some remedies (not the less great because they are primitive), still these simple cures are not adequate for the most virulent of our infections—small-pox, anthrax, sleeping sickness, and the rest. Tuberculosis is a much less formidable affair; and most often it is curable spontaneously, or with the additional help of "airing" and "salting." The unfortunate fact is that the cure of the vicious circle of complications superadded in the lung by the complex structure and functions of the organ is beyond the competence of mere hygiene and climate, and needs to be engineered by the joint efforts of general and anti-bacterial therapeutics. In the recent past these had been discredited in favour of "open air" pure and simple. There are signs of an approaching period when the Hospital treatment will be regarded as the essential and the Sanatorium as the accessory, unless the more perfect scheme can be realised of combining the advantages of Hospital and of Sanatorium treatment after the example set by Davos.

The other fact is that our only hope of stamping out tuberculosis lies in *prevention*. The only practical policy is that of not only checking the dissemination of the infection, but of stopping its reproduction by rendering the entire growing generation as tubercle-proof as possible. Short of an efficient vaccine, the best means would be to utilise our marine climates on a large scale for the benefit of all children not sufficiently protected by their native robustness or by their surroundings. The outlay would be great even with the facilities of modern engineering for supplying the simple accommodation required; but it would be a permanently profitable outlay for the purposes of health instead of serving a temporary purpose as in the case of the small-pox hospitals and similar makeshifts.

A greatly extended use of our seaside climates is also indicated for our young adults threatened with tuberculosis and for a considerable section of the large group of surgical and glandular tuberculosis.

For all these categories, in which the prevention of pulmonary tuberculosis is to be aimed at rather than its cure, our best marine climates are suitable just as they are.

For the purposes of Cure, they are suitable for another large group—that of the non-catarrhal localised pulmonary infections in their earliest stages. But it is clear that neither for these nor less still for any cases of declared catarrhal phthisis, the best of marine climates can be an ideal one, since being so variable it is too often not in its best phase. Special provisions require to be made, particularly in the direction of shelter from wind, to secure the greatest possible good with the least disadvantage, and it is probable that a great deal more may be done in the future than hitherto achieved

These, then, are the main propositions. We possess in proportion to our population an unparalleled wealth and variety of marine climatic stations. Their powers for prevention are vastly in advance of their powers for cure. Prevention is *par excellence* the use to which they should be put, and this is also the steadily growing tendency of the Sanatorium movement. In this country the place for the "Prevention-Sanatorium" or "Preventorium" is the sea-coast.

The late Mr. Richard Sumner Fowler, F.R.C.S., of Belmont, Bath, who distinguished himself particularly among the poor during the small-pox epidemic at Bath, has left by his will £250 each to the Royal United Hospital, Bath, Royal Medical Benevolent College, Epsom.

CLINICAL RECORD.

CASE OF RUPTURED OVARIAN CYST (MALIGNANT) GENERALISED PERITONITIS, WITH SECONDARY GROWTH IN UTERUS AND VAGINAL WALLS APPEARING SOME MONTHS LATER. (a)

By F. BOWREMAN JESSETT, F.R.C.S.,
AND
J. HOWELL EVANS, F.R.C.S.,
Cancer Hospital, Brompton.

E. C., æt. 35, was admitted into the Cancer Hospital, suffering from acute abdominal pain on September 12th, 1905. She had been married nine years, but never been pregnant. Menstruation regular. Very small in amount, accompanied with a good deal of pain. Always enjoyed good health until July, 1905, when she first noticed pain in the left iliac region, accompanied by constipation and vomiting. This, however, passed off in the course of a week, and she remained in good health until the end of the month of July, when a similar attack occurred lasting three days. Since this time she has noticed uneasiness in the lower part of abdomen, becoming more acute on September 2nd, accompanied by vomiting. The pain continued very acute until the time she applied to the hospital, most marked in the right iliac fossa. The abdomen had become distended, and the pain more intense, vomiting occurring occasionally.

Present State.—On examination, pulse was found to be small, quick (120), and thready; tongue red, raw, and somewhat dry. Abdomen—general distension; veins distended on wall. On palpation a tumour was felt in the lower abdomen rather to the right, but crossing the middle line. It is difficult to define the upper margin, owing to pain and rigidity of the muscles. Dulness on percussion in flanks. Respiration shallow; abdominal walls very rigid.

Per Vagina.—Whole uterus retroverted. Os and cervix infantile. She was admitted into the hospital, and Mr. Howell Evans operated on her the following day by the usual median incision. A large amount of dark fluid was found in the abdomen; the parietal and visceral peritoneum very congested; some flakes of lymph adherent to intestines. On removal of the fluid a cyst of right ovary was found, necrotic in parts, and partly solid inside as large as a fœtal head. The pedicle was ligatured, and the growth removed. Mr. Howell Evans mentioned that it had probably been twisted and ruptured. The abdomen was flushed out with saline fluid, and the parietal wound closed in layers, and a small gauze drainage in pelvis. There was some little suppuration in wound, but otherwise the patient made an excellent recovery, and was discharged on October 28th.

The pathologist reported that the cyst was partly solid, partly fluid, papiliferous, and of active cellular hyperplasia.

She applied at the hospital again in December, 1906, about fourteen months subsequent to her discharge after previous operation. For some months she has had pain in the right iliac fossa and repeated floodings. On examination nothing could be felt by the abdomen.

Per Vagina.—Uterus retroverted and mobile. In the recto-vaginal septum is a small, hard, irregular swelling with granular surface, which bleeds on examination. The finger can reach above into the posterior vaginal forum, which appears free.

On December 11, 1906, I operated on her, first removing the mass in the posterior vaginal wall freely with the mucous membrane covering and around it. The sound passed into the uterus for 3½ inches. I dilated the cervix up to No. 18 Hegar, and curretted the cavity. The scrapings were sent to the pathologist for examination, who reported them to be suspicious of new growth presenting a mass of cells of all sorts and sizes without any differentiation of tissue. I therefore at once proceeded to perform vaginal hysterectomy in the usual manner, experiencing no difficulty, with the exception of some adhesions which existed in Douglas's pouch, which were readily broken down. The vagina was plugged with iodoform gauze. The patient made an uninterrupted recovery, and was discharged on January 12 of this year.

(a) Read before the British Gynæcological Society, April 11th, 1907.

Dr. Paine, who has kindly examined this specimen, reports as follows:—

1. The ovary removed in September, 1905, showed the characteristic changes of a papillomatous cyst. There were very active proliferous changes occurring in the cylindrical epithelium covering the papilla.

2. The growths in uterus and vagina removed on December 11, 1906. The growth in the posterior wall of the uterus and vagina showed changes identical with those occurring in the ovary. In places the cystic formation with intra-cystic papilla is marked, though for the most part this is not so much in evidence as in the primary growth. There was little tendency to degenerative changes in the epithelium.

This case is of considerable interest, I think, as it is very unusual to find malignant diseases of the uterus and secondary growths in the vaginal walls following in ovarian carcinoma, but in this case, as you will see by the slides which are under the microscope, the types of disease are identical in each case.

OPERATING THEATRES.

GREAT NORTHERN HOSPITAL.

TUBERCULOUS ABSCESS WITHIN THE ABDOMEN.—Mr. PEYTON BEALE operated on a boy, æt. about 6, who had been admitted under him at Mr. Macready's request with the following history: He had suffered from severe attacks of abdominal pain associated with temporary complete intestinal obstruction for the last three years, and had had in all about twelve attacks. Within the last eighteen months a tumour was felt in the abdomen and appeared to be about the size and shape of a large sausage, freely movable, and attached to the small and large intestine, for, during the attacks of obstruction, peristaltic movement of the large intestine could be seen through the abdominal wall, and the gut was then obviously in connection with the tumour. Before and after the attacks of obstruction, a good deal of mucus and muco-pus had been passed per rectum, but there was no history of a passage of any blood. The condition was thought by Mr. Macready to be one of chronic intu susception, and, as the boy was becoming weaker, and the attacks of pain were increasing in severity, Mr. Beale was asked to operate. The abdomen having been opened in the middle line, a part of the tumour presented itself, appearing like a large yellow sausage-shaped mass soft to the touch and attached to several coils of small intestine, and also to the great omentum and transverse colon. It was at once obvious that the condition was due to a large mass of caseating tuberculous mesenteric glands which had all fused together, and had gradually encroached upon various coils of intestine. The difficulty Mr. Beale pointed out, was to know how to deal with it, for, if the mass was simply opened and the caseous material scraped away, it was fairly certain that subsequent cicatrisation and contraction would lead to complete intestinal obstruction; whereas on the other hand, if any attempt were made to free the various coils of intestine from the mass, Mr. Beale knew by previous experience that one or more fæcal fistulæ were inevitable. However, as this seemed to be the only means of preventing subsequent complete obstruction, it was adopted. In all, between thirty and forty ligatures had to be employed to separate three or four coils of intestine, and after considerable trouble the mass was isolated and as much as possible of it removed. A large gauze plug was inserted in the abdominal wound. Three days after operation, the patient had symptoms of obstruction and when the gauze plug was withdrawn, a portion of small intestine, evidently becoming gangrenous, was observed. This was brought outside the abdomen and freely opened a few hours later; and in the course of the next few days the gangrenous part was cut away, leaving a fæcal fistula. Mr. Beale remarked that this was by no means an uncommon experience in dealing with extensive tuberculosis within the abdomen; the reason why fæcal fistula was so common in these cases was that the intestine itself was nearly always tuberculous, either studded with tubercles or actually undergoing tuberculous ulceration, and so directly any portion of its blood supply was interfered with more or less of it became gangrenous and a fæcal fistula was the result. In the case he had operated upon he proposed to do an intestinal anastomosis as soon as the patient's condition should admit of it.

ACUTE MASTOID DISEASE AND BASAL MENINGITIS.—The same surgeon operated on a girl, æt. about 20, who had been admitted with typical symptoms of acute mastoid disease on the left side. An ordinary complete mastoid operation was performed, but only a very small amount of pus was found. The patient did very well, but during the next fortnight her temperature remained up between 99° and 100°, and she had marked leucocytosis. Lumbar puncture was performed; the cerebro-spinal fluid was obviously under considerable pressure, but normal in character, and it was proved to be sterile. Still, the patient did not get perfectly well. Mr. Beale gave it as his opinion that she was suffering from slight basal meningitis, but she had other symptoms which were not inconsistent with the presence of a cerebral abscess in the temporo-sphenoidal lobe; he therefore trephined her in this region and, on probing the brain in various directions found nothing abnormal. On tapping the lateral ventricle, however, a very large quantity of cerebro-spinal fluid was obtained; this also proved to be normal and sterile. During the next few days the patient was very much better—in fact, perfectly well—but one morning she became suddenly unconscious, with fits of screaming and restlessness. In two or three hours she had very marked retraction of the head and died with all the symptoms of acute basal meningitis. At the post-mortem examination, the whole of the medulla was found surrounded by pus.

TRANSACTIONS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

MEETING HELD APRIL 26TH, 1907.

The President, Mr. H. H. CLUTTON, in the Chair.

MR. LAWRIE MCGAVIN shewed

TWO CASES OF LATERAL VENTRAL HERNIA TREATED BY THE IMPLANTATION OF VERY LARGE FILIGREES OF SILVER WIRE.

Case I.—A woman, æt. 38, had a hernia at the site of an operation that had been done a year before, the gap measuring 5in. by 3in. The whole of the old cicatrix was removed by an elliptical incision 11in. in length. The divorced strip of aponeurosis was sutured to the cut edge of the posterior sheath of the rectus muscle, and upon this, as a bed, a silver wire filigree, measuring 8 in. by 4 in., was laid, the inner loops being disposed deep to the rectus muscle, and the outer deep to the oblique muscles. The remains of the rectus muscle were now brought out of the sheath and sutured, as far as possible, to the oblique muscles, over the filigree. This caused a weak spot at the middle line of the abdomen, and necessitated the opening of the sheath of the left rectus muscle, which was drawn across the middle line to meet its fellow, where it was sutured. The skin and superficial fascia were closed over all by thirty five Michel's clips, and no belt had been worn since convalescence.

Case II.—The patient had had a large hernia after an appendicitis operation. On measurement, the gap measured 7in. in length by 3in. to 4in. in width. The bowels were adherent to the skin, and she was completely incapable of any exertion, as on standing up the larger part of the abdominal contents prolapsed into the sac, causing nausea and vomiting. The patient has worn no belt since her convalescence. A similar operation to that of Case I. was done, and the result had been most satisfactory.

Mr. A. E. J. **Barker** congratulated Mr. McGavin on his results. The method was certainly superior to any the speaker had used, and saved a great deal of time and manipulation. He had used interlacing wire in about thirty cases and in only two instances had it to be subsequently removed. He referred to the respiratory embarrassment he had seen occur after the replacement of enormous herniæ. He asked whether Mr. McGavin had ever experienced much difficulty in stripping the peritoneum from the transversalis fascia.

Mr. **McGavin** said in reply that in cases presenting this difficulty he placed the filigree between the rectus muscle and of the posterior sheath. He had not had to remove the filigree in any of the sixteen cases he had done.

Mr. **Lawrie McGavin** shewed

CASE OF INGUINO-SCROTAL HERNIA IN A MALE TREATED BY IMPLANTATION OF FILIGREES OF SILVER WIRE.

The patient, a man æt. 42, had suffered from a traumatic hernia for two years. The length, from the centre of Poupart's ligament to the bottom of the scrotum was 11in., and the circumference at the widest part, which was just above the testis, was 18½in. A very large vaginal hydrocele was present, which dragged heavily on the cord. The testis and cord were therefore removed, and the two separate filigrees were used—one to defend the pubic portion of the canal, placed deep to the conjoined tendon, and the other to defend the iliac portion and internal ring, placed on the surface of the internal oblique muscle and overlapping the outer end of the inner filigree for about three-quarters of an inch.

Mr. **Douglas Drew** shewed

TWO CASES ILLUSTRATING THE USE OF A FILIGREE OF SILVER WIRE IN THE RADICAL CURE OF UMBILICAL HERNIA.

Case I.—Woman, æt. 49. The hernia had appeared twenty-five years ago. It had been about the size of a cocoanut and was irreducible. The recti muscles had been widely separated above and below the ring. The filigree, 8in. by 4in., was inserted beneath the recti muscles, which were drawn together over it, as also were the edges of the sheath.

Case II.—Woman, æt. 41. The hernia had appeared four years ago and measured 4in. in diameter. The filigree, 4½in. by 3in., was used in the same manner as in Case IV.

Mr. **Douglas Drew** shewed a case of

HABITUAL DISLOCATION OF THE PATELLA (? CONGENITAL).

Female, æt. 13 years. The child first came under observation when six years old with severe genu valgum and dislocation of the patella when the knee was flexed. McEwen's osteotomy of the femur was performed April, 1900. The present condition was much the same as seven years ago. On flexing the knee the patella slipped completely over to the outer surface of the external condyle, whereas, when the knee was extended, it lay over the extended condyle. It was suggested to treat the case by dividing the capsule on the outer side of the patella so as to allow of the reposition of the bone, and by shortening up the capsule on the inner side, and deepening the patellar surface on the femur.

Mr. **Walter G. Spencer** advised the removal of the patella, care being taken not to damage the aponeurosis.

Mr. D. **Drew** recalled a case operated on in the way he now suggested, by Mr. Pollard sixteen years ago, with an excellent result.

Dr. **Frederick E. Batten** shewed three cases of

ACUTE ATAXIA (ENCEPHALITIS CEREBELLI).

Case I.—Boy, æt. 6 years. This case was exhibited before the Society in October, 1904. In April, 1904, he vomited, had general convulsions, and passed into a comatose condition. On regaining consciousness he was wildly ataxic both as regards his legs, arms, and trunk. From this he very slowly recovered, and when exhibited before the Society in 1904 was still very ataxic. He now walked fairly well but was still unsteady, especially on the left leg. The articulation was still slow and hesitating. The reflexes were normal. Sensation to touch and pain was perfect. He could appreciate the shape of objects put into his hands.

Case II.—A boy, æt. 11, was quite well up till April 1st. He had severe headache, vomited the whole day, and was unable to feed himself or stand. On April 5th he tried to get out of bed, and walked like a drunken man. On April 9th he had marked ataxia of both legs, some ataxia of the hand, and nystagmus on looking to the left side. There was loss of tone in the muscles of the lower limbs. The knee-jerks were active, and the plantar reflexes flexor. The boy had rapidly improved, so that he now only exhibited slight ataxia in the lower extremities.

Case III.—A boy, æt. 12, had always been backward. For the last seven years patient had had attacks of petit mal. In September, 1906, he had a series of 130 fits, and was unconscious for three days. On recovery he could move arms and legs, but had no control over them, and had not been able to walk since. His mental condition was poor, his articulation was slow and jerky. There was unsteadiness of the trunk and head. There was general weakness of the arms, and a well-marked intention tremor was present. He could not walk without aid, and his gait was wildly ataxic. The knee-jerks were active, the plantar gave a reflex response. There is a lateral curvature in the dorsal region.

Dr. **Batten** referred to the favourable prospect in these cases and recalled Dr. Frederick Taylor's case that made only slight improvement in the first three years, but had perfectly recovered when seen twenty-five years later.

Mr. C. **Gordon Watson** showed two cases of

MODIFIED PIROGOFF'S AMPUTATION.

The operation was performed for very severe talipes equinovarus following infantile hemiplegia. Tenotomy of tendo Achillis, and subcutaneous division of all contracted tissues in the immediate neighbourhood. Excision of astragalus and amputation of foot in front of os calcis. Removal of internal malleolus and cartilage from lower end of tibia. External malleolus left intact, but cartilage removed. Small portion of anterior extremity of os calcis removed. Patient can now walk well, and has a very comfortable stump.

Mr. H. H. **Clutton** said that the result of this new operation was excellent.

Mr. **Reginald Miller** showed a case of

ENCEPHALITIS CHIEFLY AFFECTING THE MID-BRAIN.

Patient was a boy, æt. 3 years, under the care of Dr. Colman, at the Hospital for Sick Children, Great Ormond Street. In October last, child was suddenly taken ill with a convulsion, in which the left side of the face was drawn up, and this was followed by three weeks' unconsciousness. When seen in November there was some weakness of the right side of the face and the right external rectus with slight lateral nystagmus. There had been inability to walk or talk, extreme emotionalism, some rigidity of the right arm and leg, and a slow tremor (about 5 per second) of the head and limbs, which showed more in the proximal than in the peripheral parts of the limbs and was absent only during sleep. The fundi were normal, the abdominal reflexes absent on the right side and feeble on the left, the knee-jerks brisk and about equal, and the plantar responses flexor. The facial and ocular signs quickly cleared up and the tremor became of the "intention" type; the abdominal reflexes became normal, but the rigidity of the right side remained. He had now regained the power to walk but could not yet speak intelligibly. Recovery had been slow but continuous.

Mr. **Miller** discussed the diagnosis as contrasted with the cases Dr. Butler showed.

Drs. W. G. **Stone** and F. **Norman** showed a case of

TUMOUR OF TONGUE IN A BOY ÆT. FIVE YEARS.

The right side of the tongue had been severely bitten three years ago. Since then it was reported that there had always been a swelling under the tongue about the size of a hazel nut, with a smooth surface and of the same colour as the rest of the tongue. There was now an irregular purple swelling on the under surface of the right half of the tongue with hardened edges.

Mr. A. E. J. **Barker** said that the case was probably one of mixed lymphatic nævus, and asked if no lump had been noticed previous to the biting of the tongue.

Dr. **Stone** replied in the negative.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Obstetrics.

Meeting held Friday, April 12th, 1907.

Sir A. V. Macan in the chair.

A VULSELLUM FORCEPS.

Dr. **Ashe** exhibited a vulsellum forceps, which he had had made in order to get over the tendency of the bullet forceps to slip out of the cervix, and the discomfort attending the holding of it for any considerable period. The chief features of the vulsellum forceps were that the points interlocked instead of meeting outside, while they were flatter on the under surface than the ordinary bullet forceps so as to offer a greater resistance and not pull through the tissues. The handles were so shaped that no matter how they were held they were a great deal more comfortable. There was no difference as to the cost of production.

The Chairman, Dr. Hastings Tweedy, and Dr. Spencer Sheill complimented Dr. Ashe on his exhibit, and the latter replied.

CHART REPRESENTING THREE YEARS IN THE LIFE OF AN ECLAMPTIC.

Dr. **Spencer Sheill** exhibited a chart showing diagramatically the dates and occurrences during the last three years in connection with an eclamptic patient. He had brought the case before the Academy a year ago, and he thought the further history of the case would be of interest. About 1900 nephrectomy was done for tuberculous left kidney. In 1904 she married and became pregnant. The remaining kidney, having the extra strain of pregnancy put upon it, began to fail; and in March, 1905, when about six months pregnant, she went to him suffering from eclampsia. Induction of labour was satisfactorily done, but the child was lost. In August of the same year she became pregnant again. The usual treatment was adopted, and as far as the kidney was concerned it was fairly satisfactory. In December of the same year the kidney again showed signs of failure. In the following January, when about eight months pregnant, the symptoms became so marked that he determined to induce labour. He delivered her of a living child, and about three hours afterwards she had an eclamptic seizure. Although strictly spoken to abou the dangers of a third pregnancy, she again becam pregnant, and in November of that year the kidney showed symptoms of rapid failure. After consultation with two other doctors, it was determined, in December, 1906, when only three months pregnant, to save her life by entering the uterus. It was emptied by him under anæsthesia, and in about three days the amount of urine became normal. In January of this year it was thought advisable to prevent any further pregnancy, and after consultation, and with the leave of the husband and the patient, her Fallopian tubes were resected. The chart raised certain points of interest, such as the postponement of marriage for at least three years after the removal of one kidney and the question as to the induction of labour in order to save the life of the mother and the child. There was also the point as to the significance of the amount of urea in the urine. If he had gone by the amount of albumen he would never have done anything with the case; it never rose beyond 0.15 per cent., whereas the amount of urea excreted fell as low as 7½ grains per ounce in 14 ounces in twenty-four hours. There were also the points as to the advisability of inducing abortion, and of sterilization.

The **Chairman** asked if the urine was examined between the pregnancies, and whether she had a very small quantity of urea.

Dr. **Sheill** said the kidney was functioning absolutely normally between the pregnancies, and was quite capable of carrying on its work. The urine was examined at frequent intervals in order to be quite sure on that point.

Dr. **Hastings Tweedy** said the result had absolutely justified Dr. Sheill's treatment, but he had never heard of a woman being deliberately sterilized when no symptoms were present, and when there was no suggestion that she would ever become pregnant again. He did not suggest that anything but the right thing was done, but it was a very bold procedure, and if he had to contemplate such an action he would be very glad to be able to refer to the record of a successful result in a case of a similar kind.

Dr. **Jellett** could not agree with Dr. Tweedy as to the particular boldness or rarity of removing the tubes for renal disease. It was on all fours with the very old treatment of osteomalacia One could not wait until pregnancy in order to resect the tubes. He could not look on the patient as being a healthy woman. Her kidney might be acting at one time, but it was amply proved that it would not act under the adverse circumstance of pregnancy.

Dr. **Kirkpatrick** instanced a case of a girl, æt. 20, who became pregnant last year and had eclampsia at the time. She died with all the symptoms of failure of the kidneys. At the *post-mortem* they found she had an old and chronic tubercular disease of one kidney, which had completely destroyed its function; the other kidney was amyloid. She recovered from the eclampsia, but died some months afterwards from failure of the single kidney.

Dr. **Horne** said that, considering the age of the patient, twenty-eight, and her apparent fertility, he thought Dr. Sheill was perfectly justified in his action. If he had allowed her to become pregnant again he would probably have had to repeat the former operation with less favourable results. In his experience albumen was always found persisting in the urine six or eight months after delivery where eclampsia had occurred.

The **Chairman** agreed with Dr. Horne, and said that the chart showed very graphically the condition of the patient.

Dr. **Sheill**, replying to a question by Dr. Neil, said the patient was not on an absolute non-nitrogenous diet except when she was showing kidney insufficiency. Between pregnancies she was on a mixed diet, but warned against taking the usual amount of meat.

THE METHOD OF BIER IN GYNÆCOLOGY.

Dr. **Spencer Sheill** read a paper on the above. He said the paper dealt with Bier's treatment of disease (by hyperæmia artificially produced) as applied *locally* in gynæcology, and some actual experiences with it in a variety of gynæcological ailments were related by the author. The tendency nowadays of imitating Nature's methods of combating disease was discussed. Dr. Sheill dismissed the "arterial" hyperæmia as produced by hot air, and the "venous" form by "constriction," because he had had no experience of the former, and the latter he considered inapplicable to gynæcology. The "suction" form, creating mixed arterial and venous hyperæmia, was the kind he used, and he showed a simple form of apparatus which had been successfully used in a number of cases. The author said that in order to be beneficial the "suction" must be intermittent, and must not be so strong as to cause pain. Three minute application and one minute interval for half-hour sittings daily or weekly as the case might be, were recommended. He also spoke of the value of intermittent action, "massaging" the uterus being valuable in cases of adhesions and relaxed pelvic ligaments. Dr. Sheill had used the treatment in two cases of amenorrhœa without obvious cause, the results were negative in so far as the menses were concerned, although in one case other pelvic symptoms were relieved. A case of endometritis was very favourably influenced. In two cases of old pelvic exudate and adhesions the result was specially gratifying. The author suggested that in gonorrhœa the suction treatment would be valuable to prevent the upward spread of the infection. Also for the safe and easy removal of tenacious mucus from the cervix of nulliparas desirous of becoming pregnant. Klapp, an assistant to Bier, was quoted as recommending "suction" in cases of suppurative mastitis. Dr. Sheill described a case of his own experience—since writing the paper—the result was excellent. In conclusion, the writer of the paper expressed a hope that others in this country would give the treatment a trial and that those who have used it would compare results obtained, because he believed it to be a distinct advance in gynæcological methods.

The Chairman said the method appeared to improve the defensive force of the tissues against invasion. Personally, he did not think that the mere drawing of a little blood into the cervix was likely to have much effect.

Dr. Ashe and Dr. Tweedy also spoke, and Dr. Sheill replied.

THE REPORT OF THE ROTUNDA HOSPITAL.

Dr. Hastings Tweedy read the Report of the Rotunda Hospital for the year 1905–6.

On the proposal of Dr. Neil, seconded by Dr. Horne, discussion on the paper was postponed till the next meeting of the section.

A NEW UTERINE DILATOR.

Dr. A. J. Horne exhibited for Dr. Duke a new uterine dilator. Dr. Duke said that anyone who had performed the operation of dilatation must have noticed the contraction of the cervix uteri on the curette taking place during the proceeding. The cervical wall may also require scraping, and owing to the contraction spoken of it becomes a difficult matter, if not impossible. The canulæ shown were designed to be introduced after dilatation according to the amount of room required, the curetting being carried on through the canula, which is gradually withdrawn, thus effectually preventing the contraction of cervix on curette.

Dr. Tweedy expressed the Section's appreciation of Dr. Duke's kindness in giving them the opportunity of seeing his interesting appliance.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

Meeting held April 19th, 1907.

Dr. G. Chapman in the Chair.

The Chairman read a paper on two cases of

GLANDULAR FEVER,

occurring in a lady æt. 30, and her daughter, æt. 3½ years. There were the usual enlarged glands in the cervical region, without lesion in the throat, nose or ears to account for the adenitis. There was fever, enlargement of the spleen, and epistaxis. The child had a similar illness, but of milder character.

Dr. Porter Parkinson considered this collection of symptoms was not a definite entity, but, as in the case of purpura, it was probably due to a variety of infections.

Dr. T. R. Whipham showed a girl, æt. 8, of alcoholic parents, who had threatened to murder her. She began to stutter, and developed stridor, and deafness. Double ptosis and transient anæsthesia appeared, and there was some atrophy of the tongue. Intellectually she was bright, but supersensitive, and talked of religion, marriage, and maternity. The diagnosis lay between *neurosis* and *disseminated sclerosis*. Dr. Whipham showed a girl, æt. 11, with adherent pericardium and aortic and mitral regurgitation due to acute rheumatism eighteen months previously. The diastolic murmur had occasionally disappeared. There was systolic retraction of the intercostal spaces near the left nipple.

Dr. Fletcher Beach showed a boy, æt. 6 years, the subject of

VON RECKLINGHAUSEN'S DISEASE.

There were two growths on the head, one above the right eye and one over the occipital region. The left side of the face and the left eye were smaller than the right. There is extreme spinal curvature in the dorsal region, and much thoracic deformity. On the abdomen and back are areas of brown pigmentation, some being as large as a five shilling piece.

Dr. Porter Parkinson, showed a girl æt. 2 years and 4 months with *right-sided hemiplegia and motor aphasia* due to encephalitis superior in February. The illness began with fever and a convulsion, a week later the paralysis was noticed. For six weeks she was quite unable to speak a single word, merely screamed and made unintelligible noises, though she recognised her relations and understood all that was said to her. Since then she has gradually learnt to speak, and a little power has returned in the paralysed limbs; the electrical reactions were normal.

Dr. F. J. Poynton showed a case of

ADDISON'S DISEASE

in a girl æt. 9. For the last year she had suffered from lassitude, occasional vomiting and fainting attacks. For the last month the face had been getting darker in colour, and there is some pain in the abdomen and back. There was some pigmentation of the mucous membrane of the left cheek and soft palate, and the skin of the abdomen and back. The blood pressure was only 60 mm. of mercury, but there was no anæmia, the red cells being actually increased in number.

Mr. Duncan Fitzwilliam showed an infant, æt. 9 months, with twenty-seven abscesses distributed subcutaneously over the head, body and limbs. There was no history of syphilis, and they were probably due to the staphylococcus.

He also showed a

SYREN FŒTUS

which had a single lower extremity. The bones of the pelvis were normal; the femur was thick, and below it were two bones partly separated at the upper end. The bones of the paddle-like foot were normal. The mother was delivered at the eighth month.

Mr. G. Pernet showed a girl, æt. 3, with erythema iris on the arms, due to intestinal intoxication. Also a girl, æt. 15, with

ERYTHEMA PAPULATUM HÆMORRHAGICUM,

who was stated to be a vegetarian, having a natural distaste for meat.

Mr. Jaffrey exhibited an infant, æt. 6 months, with a cartilaginous tumour attached to the whole length of the left side of the nasal septum, filling up the left side. It bleeds very freely.

Dr. J. T. Tallent showed a case of double retained testes in a child, æt. 2½. When six weeks old a swelling appeared in the right groin, but disappeared again in about five minutes, this has frequently happened since.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Meeting at Manchester, April 19th, 1907.

Dr. E. O. Croft (Leeds), President, in the chair.

Dr. **Lloyd Roberts** (Manchester) exhibited a Malignant Ovarian Tumour removed by abdominal section from a multiparous widow, æt. 65 years. Menopause 20 years ago. Abdominal swelling had been noticed for eight months. There had been no pain or loss of flesh. The physical signs were those of an ovarian cyst with ascites. On account of the enfeebled condition of the patient a preliminary paracentesis abdominis was performed followed by ovariotomy four weeks later. The opposite ovary was cystic, and therefore also removed. Recovery was uneventful. Microscopically the growth was an adeno-carcinoma.

Dr. **Fothergill** (Manchester) showed compressed swabs for use in abdominal sections in private practice.

Dr. **Blair Bell** (Liverpool) showed a specimen of Sarcoma of the clitoris removed from a woman, æt. 56, 6-para, nine years past the menopause. A lump in the external genitals had been noticed for about six months, and caused considerable discomfort in walking. There was no pain, bleeding, or difficulty in micturition and no loss of flesh. The growth was widely removed, and consisted of a large irregularly spherical mass, more or less necrosed on the surface, and extending to the left labium minus. Microscopically it was shown to be a large spindle-celled sarcoma, the cells composing the tumour, having large oval nuclei. There was a somewhat unusual amount of inter-cellular substance.

Dr. **Arthur J. Wallace** (Liverpool) related a case in which a very large fibroid had been removed with the uterus from a woman aged 53. The tumour had burrowed between the layers of the left broad ligament and up beneath the peritoneum covering the posterior wall of the abdomen, and during operation the lower part of the descending colon and its sigmoid flexure had to be stripped off the growth. Forty hours after operation the patient began to have a continuous discharge from the rectum of dirty, watery, slimy fluid, very occasionally streaked with blood. All general and local remedies proved ineffective, the discharge persisting until the sixteenth day. Dr. Wallace was inclined to think that the cause of the condition was damage to the nervous supply of the colon during operation, with resulting vaso-motor paralysis and trophic disturbances in the wall of the bowel involved and sepsis within its canal. Six weeks after operation a temperature of 104 suddenly developed, and for a week the temperature was rarely below 100. The patient's general condition steadily improved during this time, and no cause could be discovered for the temperature. Operation wounds had healed by first intention, and there had been no return of the diarrhœa. Now, four months after operation the patient was in good health, but she still had elevations of temperature for which there was no apparent cause.

Dr. **Arnold W. W. Lea** (Manchester) related a case of bilateral axial rotation of ovarian cysts during pregnancy. The patient, aet. 27, was suddenly seized with severe abdominal pain and vomiting whilst pregnant three and a half months. A tense cystic tumour occupied the right side of the abdomen, and a smaller cystic mass was felt on the left side, the uterus occupying the central position. Abdominal section was performed. Both ovaries were converted into dermoid cysts, each of which had undergone acute torsion. The tumour on the left side had ruptured, and the peritoneal cavity contained blood. Both tumours were removed; fifteen days later miscarriage occurred spontaneously. The foetus had evidently been dead for some days. Bilateral ovariotomy has now been performed during pregnancy in at least sixty cases, and it is remarkable that in the great majority the pregnancy has continued the full term.

Dr. **Grimsdale** (Liverpool) communicated the case of K. J., æt. 29, who had never menstruated, but complained of pain in the back, which lasted for two days each month. Her general health was good. There was no cough, and no abnormal signs to be detected in the lungs. There were healed scars in the right groin, suggesting old suppurating glands, and a depressed healed scar on the inner side of the lower part of the right thigh, suggesting old necrosis of the femur; there were also some healed scars over the right tibia. The patient could not give any account of these scars. She was well developed, and apparently a strong, healthy girl. There was no abdominal tumour. The vaginal examination was made under an anaesthetic. The uterus was found to be somewhat enlarged and movable. There was a definite elongated swelling to the left of the uterus. An endeavour to pass the sound failed; it would only pass three-quarters of an inch. The diagnosis of malformation of the uterus with possibly some retention of blood, was made. The abdomen was opened, and the uterus and Fallopian tubes removed; the vermiform appendix adhered to the right tube, and also to the upper part of the rectum, into which it had opened. Both Fallopian tubes were distended with thick pus. The uterus contained caseous pus in its cavity, and also disseminated through its walls. The case was one of tubercular disease of the uterus and appendages causing primary amenorrhœa.

ULSTER MEDICAL SOCIETY.

Meeting in the Medical Institute, Belfast, Thursday, April 25th.

The President, Dr. D. P. Gaussen, in the Chair.

Dr. **J. Singleton Darling** (Lurgan) read notes of a case of "Cystoma of the Ovary," weighing 70 lbs., removed under local anaesthesia. The patient was a woman of about 75, apparently almost moribund on admission to the Lurgan Infirmary. As the symptoms were urgent, and she seemed too ill to take a general anaesthetic, Dr. Darling opened the abdomen under local anaesthesia produced by cocaine. He found an enormous cyst, adherent to the anterior wall, and drained off 48½ pints of fluid, then dissected out practically without pain the tumour, which, with the fluid measured, but not allowing for a quantity lost, weighed 70 lbs. The pulse improved rapidly, and the patient showed an extraordinary craving for food. She did well till the third day, when lung trouble set in, and she died on the fourth day, without any signs of septic trouble or any abdominal symptoms. Drs. O'Neill, Dempsey, and Fielden discussed the case. The last pointed out that if ether had been given in this case, it would probably have been put down as the cause of the subsequent pneumonia.

"THE DIAGNOSTIC VALUE OF THE OPSONIC INDEX."

A paper on this subject, by Drs. Houston and Rankin, was read by the former, In two former communications to the Society, they had described the methods used, so they did not enter into that, but gave their conclusions from a large number of examinations in various conditions. 1. In chronic affections, without temperature, the opsonic index is below normal, and remains so. 2. In acute affections the index is in every case above 1, and generally up to 4, 6, 8 or even, as in the case of the meningococcus, to 60. 3. No great stress need be laid on slight variations, as errors easily creep into the most careful work, but if the results of several examinations correspond, more value attaches to them. Examples were then given of the aid to diagnosis afforded by such examinations. (*a*) A lady had complained for some time of pain and tenderness over the ileo-sacral joint. The diagnosis lay between hysteria, a strain, or early tubercular disease. At two examinations the opsonic index was .68 and .66 for tubercule, and the diagnosis thus made was confirmed by the subsequent course. (*b*) A patient suffered from ascites and pleural effusion, suggestive of tubercule. At two examinations of the blood, the index for tubercule was normal, as it was also when the fluid was examined. A tumour subsequently developed, and the patient was found to have malignant disease of both ovaries. (*c*) A patient was admitted to the Ulster Hospital acutely ill, with a temperature of 104, and signs of typhoid, but the Widal test was negative, and the index for tubercule was 1.5 The after-progress showed the case to be tubercular. (*d*) A weak anaemic patient had suffered from mucous diarrhœa for months, which was suspected to be tubercular, but the index was normal, and the case proved to be one of pernicious anaemia, as revealed by an examination of the blood. (*e*) A young man was seen with symptoms pointing to pressure on the cord, which had been diagnosed as tubercular. The index was normal, and under antisyphilitic treatment he improved. (*f*) A patient who had suffered from septic arthritis for years, and had diarrhœa. The index for tubercule was normal, but that for staphylococcus was low. (*g*) A case of persistent frequency of micturition, with normal temperature. Coli were found in the urine, and that this was not an accidental infection was proved by the presence of a low index for B. Coli. (*h*) The last example is a most interesting one; a case of the President's, of which he will give a full account later. The patient, a lady, suffered from irregular rises of temperature of an undulatory type, exactly like Malta fever, but as she had not been out of the country for fourteen years, this was not considered a likely diagnosis. She developed an acute cystitis, and the index for Coli rose to 1.2 and 1.4. Inoculations of Coli vaccine were given till the index was raised to 3, but the febrile attacks continued to come on. Agglutination tests for the Malta micrococcus tried five times were negative, and attempts to isolate the micrococcus failed. The opsonic index was tried, and in repeated examinations was always above normal, and varied with the temperature. The diagnosis of Malta fever was made, and as it is known that in chronic cases the agglutination test fails, the failure in this case was not surprising.

Meningococcus.—For some months past they had been working specially at the meningococcus, and the difficulties of technique which constantly arose were well illustrated here. A variety of degeneration forms arose on culturing the coccus, and accurate counting was impossible at first; but happily Professor Summers had discovered a medium on which the coccus grew well, a special sort of peptone with ascitic fluid. On this sub-cultures were taken daily, and they found that at the thirty-fifth generation, which they had now reached, degeneration forms had almost disappeared, and no agglutination occurred, as generally was the case early. For their experiments they used six-hour growths in a thick emulsion. They found that the opsonic power of normal serum was extremely low, but on the other hand the opsonic power of the serum from cases of cerebro-spinal meningitis was very high. Their routine was for two men to count in every case, as a control. In many cases the leucocytes were so packed with the cocci that the latter were unaccountable, and these they took as containing fifty, though, in many cases, it must have been much more. They had examined sixty-four cases, and details of tests were given. The general results were as follows:—

(1) From the sixth day all showed an opsonic index over four. Sometimes it was high on the second day, often on the third, and always on the sixth.

(2) The opsonic index seems a more delicate test than agglutination, which was never seen till the index was five times the normal.

(3) The combination of the two tests was most valuable for diagnosis.

(4) From the very definite results obtained, it seems that this method will prove of value in diagnosing sporadic cases, and cases of posterior basic meningitis.

(5) It may also be relied upon to show if a suspected coccus is the true meningococcus.

(6) It may be used to test the efficacy of sera recommended for treatment. In the case of one serum advertised as having an agglutinative power of 1 in 50,000, they found it to be nil at a dilution of 1 in 3! This was confirmed by its clinical results, which were nil. It was, of course, possible that certain sera were specific for certain varieties of the coccus only, and this point they were endeavouring to elucidate. There may be different strains of the coccus in different places, as is the case with streptococcus, apparently, though not with A, the typhoid bacillus, as tested with Widal's reaction, which is universally applicable.

The paper was criticised and the writers warmly thanked, by Sir John Byers, Drs. Calwell, Robb, Cecil Shaw, and McQuitty.

Dr. Hanna read short notes of a case of "Extradural Abscess," following middle ear disease, with recovery after operation.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, April 27th, 1907

Treatment of Pleurisy.

The treatment of pleurisy consists in obtaining the absorption of the effusion or in evacuating it if necessary.

Thoracentesis, hitherto systematically recommended, becomes inadvisable only under two conditions: where the abundance of the liquid threatens to compromise life or where the effusion is absorbed but slowly and at the end of a month has not perceptibly diminished in volume.

On the left side thoracentesis is indicated when the heart is deviated towards the right and on the right side where the liver is pushed below the false ribs. The quantity of liquid to be drawn off at one sitting is variable, but a quart and a half may be extracted provided the aspiration is not done too rapidly.

During the acute period the patient should be put on milk diet, two quarts a day.

As to medicinal agents, Prof. Robins prescribes the first day two grains of calomel every hour for four hours as a purgative. The following day, ten grains of salicylate of soda four times a day for six or eight days.

To persons of strong constitution, and in whom there exists no displacement of the heart, jaborandi may be given in infusion (1 drachm macerated in half a glass of brandy for an hour, then add 6 ozs. of boiling water and leave to infuse twenty minutes; to be taken in one dose).

In patients depressed, or where the heart is deviated, jaborandi is dangerous.

Blisters are useful when the liquid remains stationary and may be applied every five or six days.

If the temperature is high one of the following wafers may be given in the evening:—

Bi-hydrochlorate of quinine, grs. 8
Pyramidon, gr. 4

In case of violent pains in the side, wet cupping or a subcutaneous injection of morphia will give relief.

If oliguria is present, the diuretic mixture

Oxymel of squills, oz. 1
Acetate of potash, grs. 30
Nitrate of potash, grs. 30
Infusion of broom tops, ozs. 6

A tablespoonful every two hours.

When the adhesions have formed the patient can get up and begin to take substantial food, and:

Arseniate of soda, gr. 1.
Iodide of potassium, drachm 1.
Water, ozs. 10.

Two tablespoonfuls daily before meals.

Igni-puncture or large applications of tincture of iodine may be ordered to stimulate the vitality of the tissues, while the patient will practise respiratory gymnastics against muscular atrophy. Lying on the healthy side he will make eight or ten deep inspirations, to dilate the compressed lung, several times a day.

When possible a hydro-mineral treatment may terminate the treatment. Sulphurous springs for those who cough and are a little oppressed; arsenical for those who cough no longer.

WRITER'S CRAMP.

The treatment by elastic ligature employed by Bier for arthritis has been also used with success in such muscular disorders as contractions, spasms, cramps, etc.

A typical case of writer's cramp is one of the most recent triumphs of this method. A man, æt. 37, employed in a commercial house, complained of difficulty in writing, which had already lasted fifteen years, and which a neurologist diagnosed as writer's cramp. When he wanted to write the patient was seized with stiffness in the fingers, which prevented him from forming the letters, and more especially f, g, h, m, n, u. The stiffness varied in intensity from one day to another, and was less marked in the evening than in the morning. The general condition of the patient was excellent, but he was evidently of a nervous and impressionable temperament. Different treatments were employed without success; prolonged rest from writing, strychnine, galvanisation, gave but temporarily relief, and finally he was told that his trouble was incurable.

M. Hartenberg advised the treatment by elastic ligature, consisting in winding around the arm, above the biceps, an elastic band, sufficiently tight to arrest the venous circulation below the band, and maintained twenty minutes morning and evening. The results were remarkable. At the end of a fortnight the patient wrote a letter to his doctor showing a considerable improvement in the writing, and two months later a second to announce a complete cure.

GERMANY.

Berlin, April 26th, 1907.

At the Medizinische Gesellschaft Dr. Kausch spoke on

Cancer of the Stomach and Surgery.

His observations were based on the result in the surgical treatment of cancer of the stomach obtained by Mekulicz in the Breslau Klinik. Resection was performed in 163 cases. During his last four years the mortality had been 33.8 per cent., when all deaths occurring within thirty days of operation were reckoned as due to it. If other surgeons obtained better results, it was due partly to a selection of cases, and partly to this fact that the operation as performed by Mekulicz was a very radical one.

An improvement in the statistics might be expected with improved technique and advancement as regarded asepsis; much would not be made out in these ways, however. The most important improvement would take place when the cases for operation reach the surgeon earlier. In 92 cases that left the Klinik as recovered, later inquiries had been made as to their fate; 62 were already dead of recurrences, only a very few of late recurrence, that was, more than three years after operation. This gave a percentage of 14 alive more than three years after operation.

Boas had recently expressed a doubt as to whether cases could be sent for operation much earlier, as in some cases the symptoms only made their first appearance later on in the disease. Mekulicz's observations also showed that in many among those who came soon after the onset of symptoms, resection was no longer possible, more, in fact, than among those who had suffered a longer time, and in whom a tumour gradually developed. On the other hand, the prognosis was more favourable in those who had been only a short time ill, and when the strength was not exhausted.

Gastro-enterostomy was indicated only when the motor disturbance was great. The speaker rejected jejunostomy completely.

Exploratory laparotomy could not be too much commended in all cases in which symptoms and examination gave grounds for a suspicion of carcinoma which it could not be proved positively to be present.

Hr. Ewald laid stress on the difficulty of diagnosing cancer even when all aids to diagnosis were made use of, and of fixing the moment when operation should be performed. That operation should be performed when a tumour could be felt there could be no question, but these cases formed only a fractional part of the whole. During the last ten years he had had 255 cases of cancer of the stomach in the wards; but in spite of every disposition to operation, only 59 of them had been found suitable for operation. No change could be expected at present, as patients could not yet be brought to understand the need for exploratory laparotomies.

The Deutsch Med. Zeitung, April 11th, has a reference to a paper by Priv. Doc. Dr. Wandel on

The Pathology of Poisoning by Lysol and Creosol.

Lysol, which acts as a poison on the animal system by the creosol given off, causes injury at the spot to which it is applied, and by reabsorption passes to the cells, first to the cell protoplasm, later to the pigment substance, the injury being proportional to the concentration of the solution. Even with comparatively weak solutions of creosol considerable injury is inflicted on the blood and on the blood vessels, where it is taken up from the intestinal canal, more especially the portal vein that returns the refuse of the blood to the liver. This shows the more marked cell injury, from slight parenchymatous degeneration to total destruction, as in acute yellow or red atrophy. The liver collects the creosol out of the intestine, and furnishes the material for an antidote in the shape of its constituent carbo-hydrates and albuminous bodies. In this way the liver loses an essential constituents of its protoplasm, that is expressed histologically in a washed out look in the cells, in disappearance of glycogen in the wider circle around the portal vein, whilst the cells in the hepatic vein show minor changes—a proof that here the non-poisonous combination of creosol with glycopurin of sulphuric acid is present, by which excretion throughout kidneys takes place. In case of graver poisoning there is total disappearance of cells, and nuclei in the liver become scarcely capable of regeneration, thus necessarily leading to substitution of connective tissue, if consistent with prolongation of life at all. If free creosole finds it way in large quantities into the blood tract, it shows itself as a poison here as in the portal vein: cases of hæmoglobinuria in lysol poisoning are explained in this way. It acts further as a protoplasmic poison in all organs to which it gains access in a free state. Tolerance for creosoe independent of the species of animal and the contents of the stomach is dependent on the material present in the liver capable of combining with it, and secondly, on the secretion of bile by which extraordinarily large quantities of creosol are removed from the liver and carried into the intestines. From this they are again absorbed, and in thinner concentration combine again in the liver. The enormous production of bile in some herbivora perhaps explains the tolerence of rabbits, for instance, in regard to lysol.

The heart and brain suffer injury when the liver does not succeed in passing the creosols, or when they escape it when absorption takes place through the lungs. Large quantities can be rendered innocuous by passing through the liver. The renal epithelium is first damaged when free uncombined creosols circulate in the blood. The albuminurias present at the early stage are probably of toxic hepatic origin. They generally disappear more quickly than the toxic hepatic carbohydrature which persist after the other symptoms of poisoning have passed off.

AUSTRIA.

Vienna, April 27th, 1907.

Contractions in Right Hand.

At the "Gesellschaft fur Innere Medicin" Salomon exhibited to the members a peculiar case of contraction in the right hand. The patient was æt. 42, and a teacher in an elementary school. The disease is attributed to writing, drawing, and playing the harmonium, which he is now unable to accomplish. There was no particular weakness, only cramp at first, which was followed within eight days by œdema of the whole hand, and fourteen days later by shaking in the right fore-arm with severe pain in the right hand. The first impression was of its being an athetosis located in the one hand, and this opinion was supported by the conjunction of pneumonia and a transient form of paralysis attacking the left side. From these symptoms the morbid changes appeared to indicate an encephalitis, as frequently appears in children where cerebral paralysis is dominant. The cause of the athetosis is usually a morbid centre in the thalamus or in the region of the optic thalmus, such as the lenticular nucleus and the processus cerebelli ad corpora quadragemina. The same symptoms have been obtained by injuring the cortical of the brain in this region, which adds to the complexity of the symptoms.

In addition to this the patient had suffered for five years previously from neurasthenic symptoms, such as narrowing of the field of vision, functional paresis of the left extremities, œdema of the hand associated with intense pain that drugs could not relieve.

Fuchs said he had repeatedly examined this patient, and concluded that it was not hysteria, but organic in origin. The movement of the right arm led him to diagnose athetosis; the tendon reflex on the upper and lower part of the right arm was accentuated, agreeing with the athetosis on this side; also clonus of foot and patella of the same side. The Reflexes of the abdomen scrotum and soles of the feet were weaker on the left side than the right. The palate and fauces were more tense on the right side than the left, indicating a paresis of the tensor veli palati of left side.

If we consider these symptoms in conjunction with the history which commenced with an attack of influenza producing encephalitis, probably the pyramidal path on the right side became involved with hemiparesis on the left side, and weakening of the cutaneous reflex. Later the disease seems to have extended to the optic centre with the resulting hemianopsia. The third centre affected produced the right hemiparesis in the upper extremity and athetosis, with clonus in the lower extremity with increased cutaneous reflex but no "Babinski." Conclusions arrived at were—a morbid centre in the subcortical path (motor), probably in the region of the process, as cerebelli ad corpus.

Although the case was at first diagnosed as one of hysteria, Fuchs avowed he never saw a symptom with the hysteria to confirm this opinion.

Chromaffine System.

Wiesel again brought forward his chromaffine connected with renal cardiac hypertrophy. In patients that die from chronic nephritis associated with cardiac hypertrophy he has always found a well-defined elovation in the medullary substance, in many cases eight to ten millimetres wide, while the corticle substance is not diminished, but has a normal appearance. Histologically there is an hypertrophy of the medullary substance and an increase in the chromaffine cells, but no other pathological change is present. In cases where the disease is of a relatively short duration there is an increase of the medullary substance from the accumulation of cells apparently induced by the sympathetic ganglia. How this cardiac hypertrophy coincides with the chromatic change he has no positive hypothesis to offer, but is under the impression that the hypertrophy in the chromaffine system precedes the cardiac hypertrophy. In cases of acute nephritis where no cardiac hypertrophy existed, there was no increase of the chromaffine system, from which he reasons that the cardiac hypertrophy always succeeds the chromaffine system.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

The Royal Visit to Glasgow.—During their three days sojourn in the western capital their Royal Highnesses the Prince and Princess of Wales fulfilled a number of engagements in connection with the medical and educational affairs of the city. On April 23rd, after having received the Freedom of the city the Prince and Princess drove to the University to take part in the graduation ceremonial and to inaugurate the new medical and natural philosophy departments. In the Bute Hall the proceedings opened by the Principal calling on the Dean of the Faculty of Law to present for the degree of LL.D. "certain persons," as the phrase goes, and first in the list of distinguished recipients came the name of the Prince and Princess. The Prince stood patiently in front of the Chancellor as his long list of titles was read out to the assembly, and having been capped by the Chancellor and robed by the Bedellus, he shook hands with the Chancellor and resumed his seat. A similar ceremony was also gone through by the Princess. The LL.D. was also conferred on other distinguished persons, including the Lord Provost of Glasgow, Sir William Copland, Miss Galloway, Secretary of Queen Margaret College, Professor Jules Henri Poincaré, Sorbonne, Paris, Professor J. G. McKendrick, Principal Macalister, Professor Harnack, Berlin, and others. After the capping was over, the convener of the new buildings committee, Professor Gray, read a statement concerning the buildings, and thereafter the Prince of Wales delivered an address, in which he alluded to the vitality which the ancient seat of learning showed, and its prompt recognition of the development of scientific study and teaching required by the practical spirit of the age. Leaving the Bute Hall the Prince and Princess and the platform party then went directly to the new buildings in the immediate vicinity, and without further formality declared them open. Luncheon was served in the large laboratory of the natural philosophy department, and at its termination the Royal party left the university to fulfil other public engagements.

The Royal Infirmary.—On April 24th the Prince and Princess came into the city to lay the foundation stone of the new reconstructed Royal Infirmary. On their arrival they were received by the Lord Provost, who presented to them Mr. Hedderwick, chairman of the managers; Mr. McCowan, convener of Finance Committee; Dr. Neil Carmichael, convener of medical committee; Dr. Middleton, Dr. Barlow, and others. Mr. Hedderwick then read an address from the managers to their Royal Highnesses, and in reply the Prince of Wales said "The Princess of Wales and I thank you heartily for the kind welcome given us here to-day. When invited to Glasgow it was a special satisfaction to be asked to join this important undertaking—the reconstruction of the Royal Infirmary—for I sympathize with the progressive spirit of the citizens of Glasgow who realize that, notwithstanding the great work the institution has accomplished, it is now neither in construction nor equipment capable of meeting the medical and surgical requirements of to-day. I congratulate Glasgow on its decision to make this reconstruction a memorial of our late beloved Sovereign Queen Victoria. We are gratified by your kind tribute to the interest taken by the King, the Queen, and my family generally in the welfare of the sick poor. Every year's experience on the work of our hospitals, so nobly supported by voluntary aid and by the gratuitous services of those most eminent on medicine and surgery impresses one with the vital importance of guaranteeing to the public, through whose liberality these enormous institutions are maintained, that they are administered in a business-like system. Before proceeding to lay this foundation stone I beg to commend this splendid work to all who can afford assistance in raising the large sum still necessary for the completion of the scheme." His Royal Highness then, in the usual form, declared the stone to be well and truly laid. The ceremony concluded by a prayer by Dr. Donald Macleod. Afterwards the Royal party were conducted over the Electrical Pavilion by Dr. Macintyre and Dr. Riddell. Amongst other novelties shown them was a gramophone record of the voice of a patient who had undergone an extensive operation on the tongue. On their departure a cheque for £100 from the Prince was handed to Mr. Hedderwick.

CEREBRO-SPINAL MENINGITIS.—This disease is still prevalent in Edinburgh and Leith, 35 cases having been intimated in Edinburgh during April, and 31 in March. Although not excessively numerous, the mortality among the cases has been very great; probably over 90 per cent. In Leith the Public Health authorities have isolated the meningococcus from the noses of contacts, and accordingly these have been isolated in a reception house, and are having their noses and throats disinfected. The sudden drop in the number of cases notified within the last month is believed to be due to this system of controlling persons belonging to infected households.

POST-GRADUATE WORK IN EDINBURGH.—The resuscitated post-graduate course held in Edinburgh last year met with so large a measure of success that it will be repeated in an extended form this September. Last year the course lasted for three weeks; this year it is proposed to be divided into two courses of a fortnight each, the second supplementary to the first, yet each more or less complete in itself. In certain of the classes the members will be limited—diseases of the blood (elementary and advanced), bacteriology (elementary and advanced), gastric methods, pathological methods, opthalmoscopy, refraction, diseases of the throat and ear, and X-Ray work, and for these an additional fee of 1 guinea will be charged. Otherwise, the composite fee for the month is 5 guineas, for either fortnight 3 guineas. The course this year will be a very complete one, and the time-table has been so arranged that no clashing will take place. Dr. Edwin Bramwell, 3, Drumsheugh Gardens, will again act as honorary secretary, and Mr. Stirton, University New Buildings, as secretary of the course.

BELFAST.

PUBLIC HEALTH PROSECUTIONS.—A secondary effect of the Health Commission is seen in a remarkable activity in the Public Health Department in instituting prosecutions for breaches of the by-laws. One of the chief complaints against the department for years past has been their apathy in prosecuting offenders, so that the by-laws relating to public health were simply scoffed at by those whose interest it was to infringe them. Last week in the Summons Court three cases of this sort were heard. In the first a milk vendor was summoned for milking a cow, "his hands not being thoroughly clean and free from all infection and contamination." The defendant said he had never heard of the regulation, which was no doubt quite true, for few people have done so, but he promised future attention to it, and was let off with a fine of 10s. and costs. In the second case another milk vendor was summoned for failing to take reasonable and proper precautions in conveying milk for sale. This was the first prosecution aimed against a practice common in Belfast—that of collecting kitchen refuse from houses where milk is delivered, and taking it off in the milk cart, as food for pigs. It is, of course, a most objectionable plan, and one often sees tubs and buckets piled high with disgusting rubbish, among the milk cans. The magistrate said that it was most important that persons distributing milk should distribute it from carts on which there was nothing but milk. If there was refuse it might directly or indirectly lead to contamination. The practice must be stopped, and the case against the defendant would be adjourned for four weeks to see if there was any repetition of the offence. In the third case, the River Plate Fresh Meat Company, Ltd., which has branches in various parts of the city, as well as in England, was summoned for exposing for sale putrid sausages, and was fined £10 and costs.

CEREBRO-SPINAL MENINGITIS.—During last week there were 36 cases of this disease notified, and 24 deaths, bringing the total cases up to 337, with 227 deaths. In Purdysburn Fever Hospital there are at present 107 patients, of whom 43 are cerebro-spinal meningitis, and ten out of the twelve deaths which occurred there during last week were from that cause.

THE HEALTH COMMISSION.—The Commission has resumed its sittings, and has begun to hear evidence on the water supply. A report will be given next week.

LETTERS TO THE EDITOR.

MILK AND TUBERCULOSIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is gratifying to me to know that "A Family Doctor" has found my letter "interesting and even amusing." Where the amusement comes in he does not tell us. To my mind, the matter is much too serious to have an amusing side, however presented. It is to "the practical point of view" that I have desired to call attention, and to keep it fixed.

While I admit that "it is probably correct that 'live' tubercle bacilli can be conveyed in milk," I not only seem to suggest, but do actually maintain, that "although milk thus (said to be) infected may be partaken of in any quantity, the danger of setting up tuberculosis in those fed upon it is never to be regarded seriously."

I ask "A Family Doctor," as I asked before, to refer me to a solitary case in which there was even a probability that tuberculosis had been conveyed by milk, and unless he can do so I have a right to say that the idea is a pure assumption. A case was reported in Belgium where a young lady in a school was said to have contracted tuberculosis by drinking the milk of a tuberculous cow kept on the premises. But it was promptly disavowed on the discovery that the pupils did not consume any of the milk of this cow. In reply to this question, I do "hold the same opinion with regard to milk containing (it is said) the contagion of typhoid fever." Will he answer this question? What is the contagion of typhoid fever? I anticipate his answer, viz., the bacillus typhosus. Does he not know that in the case of the Maidstone epidemic (King's Lynn also) not one solitary bacillus was found, although the most experienced bacteriologists were engaged in the search for it? Does he not know also that many epidemics have been recorded in which it was "impossible to accuse the water supply?" I refer him to special report upon the very serious epidemic which broke out among the reserve troops of the United States during the American-Spanish War. In the first instance, the Army medical officers attributed it to the water supply, but a Special Commission proved that this was impossible. It would occupy too much of your space to give the most concise epitome, and I must refer him to the report published in the *British Medical Journal* some time back. I presume "A Family Doctor" holds that milk containing the contagion of typhoid fever could only do so by the addition of what he would call infected water. The *contagion* of typhoid fever has yet to be discovered.

If we have not yet attained to a "scientific demonstration of the entire sequence of contributory causes, and of the mode of attack in tuberculosis," how are we to adopt means "to prevent the dissemination of the poison"? He admits the effect of "contributory causes," but I presume he is of opinion that there is one *essential* cause, viz., the tubercle bacillus, and that without it there can be no tuberculosis. Does he not know that the tubercle bacillus has never been found in the early stage of the disease, and that it is not found in the sputum until necrosis has set in? Moreover, it is often absent from the sputum in the last stage of pulmonary tuberculosis.

Perhaps "A Family Doctor" will be good enough to give us his views as to how the cow gets tuberculosis. Until he gives us his explanation, I refrain from trespassing further on your space.

I am, Sir, yours truly,
Geo. Granville Bantock.

April 27th, 1907.

"THE TOOTH-BRUSH IN SCHOOLS."

To the Editor of The Medical Press and Circular.

Sir,—I do not pretend to judge of the way in which other special subjects are dealt with in your paper; but I find always that your editorial utterances upon dental questions are based upon scientific knowledge and inspired by common sense. This is eminently the case in your paragraph under the above heading in your last issue. It is amazing to see the amount of neglect which teeth of first rate structural quality will bear without injury, whilst no amount of care will save from early destruction teeth the enamel and dentine of which are imperfectly formed and calcified. If, by the use of the tooth-brush, especially with soap or some simple antiseptic tooth powder, children of the poor can be made to keep their mouths clean, some good may be achieved; but the efforts of sanitarians ought to be mainly directed to improvement of the general physique. Rickets is the cause of early tooth decay in a vast proportion of poor children. The teeth are dermal, not osseous appendages, and their destruction in rickets is perhaps due as much to the foul state of the mouth, which always accompanies the disease, as to the inferior quality of the dental tissues, which is also always observable. Rickets is virtually always due to improper food and feeding. If, therefore, mothers were taught, and made able to suckle their offspring for the proper period; and if they were taught, and made able to feed their children properly during the first five years of their lives, much of the tooth degeneration now prevalent would be put an end to. It must be always borne in mind that enamel and dentine once fully formed are physiologically unalterable, and that the exteriors of the crowns of all the permanent teeth being fully calcified by the fifth year, no treatment directed to improvement of the tissues can be of any avail after that age has been passed.

I am, Sir, yours truly,
A Hospital Dentist.

London, W. April 25th, 1907.

RAILWAY DUST, DIRT, AND DARKNESS.—WHY?

To the Editor of The Medical Press and Circular.

Sir,—May I, as a medical man, trespass upon your space to state a case and to propound a query?

1. I live near Victoria Station and have relatives residing near the Crystal Palace.

2. On Sundays I frequently journey to the station nearest to my relatives, which happens to be on the L.B. & S.C. suburban line—about midway between Victoria and London Bridge Stations.

3. The journey from Victoria is on Sundays so unspeakably depressing that I elect to travel *via* District Railway from Victoria to Monument Station, cross London Bridge, and proceed from the station of that name to destination.

4. Travelling second class, I seat myself in one of the damp, dark, dusty, dirty, deplorable dens, misnamed compartments.

5. Before the train crawls out of London Bridge Station, I invariably sneeze and continue sneezing until New Cross is reached. Next day there is sore throat—of course.

6. Why should these things be?

Will *you*, Mr. Editor, cast your X-ray light upon this problem and earn the lasting gratitude of

Yours ever,
Idris ap Harrby.

London, S.W.,
St. George's Day, 1907.

[The bacteriology of the railway carriage is by no means exhausted. Anyone with a sensitive nasal membrane travelling on the particular line mentioned is apt to learn that pathogenic organisms are constant travellers in its cars. Perhaps some of our readers may be able to offer some satisfying suggestions to our correspondent. A good deal might be said about the political side of the question, and the slothful ways of monopolist and non-competitive companies; but that lies somewhat outside the scope of a medical journal.—Ed. M.P. & C.]

OUR CLIMATE.

To the Editor of The Medical Press and Circular.

Sir,—It is of the greatest importance that when we are discussing the climate of any district we should look carefully into the nature of the soil—that is, into its geological character. I was surprised at the way in which the late discussion of the Balneological Society seemed to show great ignorance of this matter. The variations in the atmospheric differences between the East Coast and the West of England depend on the character of the soil, more than upon anything, and it would be well if those who are interested in climatology would study geology more carefully than they are doing.

I am, Sir, yours truly,
Robert Lee.

Pwllheli, North Wales.

OBITUARY.

JOHN PICKERING BATES, M.R.C.S. (England).

On April 21st, there died at his residence, near Morpeth, Dr. John Pickering Bates. Receiving his early education at the Grammar School of King Edward VI., he chose medicine as his profession, and pursued his studies in both the Edinburgh and London Schools, qualifying M.R.C.S. in 1855. At South Shields he pursued for many years a successful and influential practice, among the public appointments he held being that of police surgeon. On retiring into private life, he returned to his native town, for which he had ever a deep affection. Dr. Bates was a student in other lines than those specially pertaining to his profession. He was well read in the histories of ancient empires and civilisations; and took a keen interest in antiquarian subjects. He had travelled much in Europe and also in the north of Africa, and had a special liking for the recent discoveries of the Egyptologists, not a few of which he had visited.

Towards the end of last summer it became known that Dr. J. E. Brooks, of Colwyn, is to be presented with a beautiful silver tray on the occasion of his retiring from practice in that town.

Dr. John Carswell, who was shot with a revolver and severely wounded by a man named William Purves in Duke Street on Tuesday afternoon, is making satisfactory progress. His injuries, however, are more severe than was at first believed.

NEW BOOKS AND NEW EDITIONS.

The following have been received for review since the publication of our last monthly list :—

- Appleton, Sidney (London).
  - Diseases of the Lungs. By Robert H. Babcock, A.M., M.D. Illustrated. Pp. 809. Price 25s. net.
- Arnold, Edward (London).
  - A Handbook of Skin Diseases and their Treatment. By Arthur Whitfield, M.D., F.R.C.P. Pp. 320. Price 8s. 6d. net.
- Bailliere, Tindall and Cox (London).
  - Ulceration of the Cornea. By Angus Macnab, B.A., B.Sc., &c. Illustrated. Pp. 196. Price 5s. net.
  - The Diagnosis and Treatment of Pulmonary Consumption. By Arthur Latham, M.A., M.D., F.R.C.P. Third Edition. Pp. 260. Price 5s. net.
  - Manual of Anatomy, Systematic and Practical, including Embryology. By A. M. Buchanan, M.A., M.D., &c., &c. Vol. II. Illustrated with 631 drawings, coloured and plain, mostly original. Price 12s. 6d. net.
  - Treatment by Hypnotism and Suggestion, or Psychotherapeutics. By C. Lloyd Turkey. M.D.Aberd. Fifth Edition, revised and enlarged. Pp. 418. Price 10s. 6d. net.
- Cassell and Company, Limited (London).
  - First Lines in Midwfery. A Guide to Attendance on Natural Labour for Medical Students and Midwives. By G. Ernest Herman, M.B. Lond., F R.C.P. New edition. Pp. 222. Price 5s.
  - Diseases of Women (A Clinical Guide to their Diagnosis and Treatment. By George Ernest Herman, M.B., F.R.C.P. Illustrated. Pp. 900. Price 25s.
  - Worry: The Disease of the Age. By C. W. Saleeby, M.D., F.R.S. Pp. 312. Price 6s.
- Churchill, J. and A. (London).
  - On Diseases of the Rectum and Anus. By Harrison Cripps, F.R.C.S. Third Edition. Illustrated. Pp. 588. Price 10s. 6d. net.
  - Cancer of the Rectum : Its Surgical Treatment. By Harrison Cripps, F.R.C.S. Fifth Edition. Pp. 255. Price 5s. net.
  - Nursing, General, Medical and Surgical. By Wilfred J. Hadley, M.D., &c., &c. Second Edition. Pp. 370. Price 3s. 6d. net.
  - Lectures on Medicine to Nurses. By Herbert E. Cuff, M.D., F.R.C.S., Fifth Edition. Pp. 269. Price 3s. 6d. net.
- Heinemann, William (London).
  - Metabolism and Practical Medicine. By Carl von Noorden, Professor of the First University Medical Clinic, Vienna. Vol. I.: The Physiology of Metabolism. By Adolf Magnus-Levy, Berlin. Vol. II.: The Pathology of Metabolism. By Carl von Noorden, Fr. Kraus, Ad. Schmidt, W. Weintraud, M. Matthes, and H. Strauss. English Issue under the Editorship of I. Walker Hall, Professor of Pathology, University College, Bristol. In three volumes. Pp. 452 and 525. Price £2 12s. 6d. net.
- Lewis, H. K. (London).
  - Police-Surgeon's Emergency Guide. By C. Graham Grant, L.R.C.P. & S. Edin. Pp. 77. Price 2s.
- Lippincott Company, J. B. (London).
  - International Clinics: A Quarterly. Edited by W. T. Longcope, M.D. Vol. I. Seventeenth Series, 1907. Pp. 318. Price 35s. net.
- Longmans, Green and Co. (London).
  - The Essential of Chemical Physiology. By W. D. Halliburton, M.D., LL.D., F.R.S. Sixth Edition. Pp. 258. Price 4s. 6d. net.
- Maclehose, James and Sons (Glasgow).
  - Eye Injuries and their Treatment. By A. Maitland Ramsay, M.D. Pp. 210. Price 18s. net.
- Macmillan and Co., Ltd. (London).
  - Inflammation: An Introduction to the Study of Pathology. By J. George Adami, M.A., M.D., F.R.S., Pp. 240. Price 5s. net.
- Philip and Son, Ltd., George (London).
  - Builders of the Body: Or Lessons on Food Values. By Eustace Miles, M.A., and Miss M. John. Pp. 179. Price 1s. 6d.
- G. A. Putnam's Sons (London).
  - Alcohol: The Sanction for Its Use. Translated from the German by Dr. J. Starke. Pp. 317. Price 6s.
- The Public Health Engineer (London).
  - The Disinfectant Value of Chlorine. By Eminent Specialists. Pp. 62. Price 5s. net.
- Schulze and Co., Otto (Edinburgh).
  - Letters on Psychotherapeutics. By Professor H. Oppenheim, of Berlin University. Translated by Alex. Bruce, M.D., &c., &c. Pp. 60.
- Spottiswoode and Co (London, E.C.).
  - The Dentists' Register: Printed and Published under the Direction of the General Council of Medical Education and Registration of the United Kingdom, pursuant to an Act passed in the Year XLI. and XLII. Victoriæ, Cap. XXXIII., entitled an Act to Amend the Law Relating to Dental Practitioners. 1907. Pp. 251. Price 3s. 4d.
- University Press (Manchester).
  - A Comparative Study of the Influence of Cod-liver Oil, and Cod-liver Oil Emulsion, upon the Nutrition of Normal and Tuberculous Pigs. By J. W. Wells, M.D., D.P.H., F.C.S. Pp. 83. Price 2s. 6d. net.
- Turney, F. S. (London).
  - The Cure of Cancer, and how Surgery Blocks the Way. By John Shaw, M.D., Lond. Pp. 229.
- Wright and Co., John (Bristol).
  - Invalid and Convalescent Cookery. By Mary E. Birt. Pp. 23. Price 6d.

At the meeting of the Limerick Guardians on April 18th, a letter was received from the Local Government Board stating that, in reply to a resolution of the Guardians asking for a sworn inquiry into the election of Resident Medical Officer of the Union, the Board were unable to accede to the request.

REVIEWS OF BOOKS.

HEWITT ON ANÆSTHETICS. (a)

Dr. Hewitt's book on Anæsthetics has already become so well known in its first and second editions, that we are sure there will be many to welcome this, the third, which not only embodies all that was best in its predecessors, but contains fresh and useful features besides. Of course it has been necessary to incorporate a new chapter on ethyl chloride, which has grown so rapidly in favour in the last few years, though oddly enough we learn that it was used in surgical practice as long ago as 1847. We rather gather that the author is not much attached to this drug, although he does not say so definitely. Indeed Dr. Hewitt throughout the book is rather cautious about committing himself to dogmatic statements, which is sometimes rather disappointing when one turns to an anæsthetist of his experience for specific guidance. But, on the other hand, this characteristic gives him the opportunity of setting forth the views and opinions of others the more impartially, and this he does scrupulously. There is a good deal of new work to record in connection with chloroform-anæsthesia, especially with regard to percentage-dosage and mechanical methods of administration, and here again we find Dr. Hewitt shrinking from the newer plan, though giving full and fair descriptions of the Vernon-Harcourt and other inhalers, both in their conception and in their construction. No doubt an experienced and skilled anæsthetist can keep his deaths from chloroform down to a very low point; but we have to remember that owing to the extent to which ether is used many men in general practice have comparatively little experience of chloroform-administration, and that the dangers of unconscious over-dosage are proportionately increased. No doubt, too, the inhaler at present made and used is not ideal; there are inconveniences and drawbacks of one kind and another, but can it be doubted that in these scientific times a type will some day be evolved which will come into universal use? One cannot believe that empirical dosage will eventually triumph over exact measurement. Fresh evidence is brought forward in favour of shock, especially of the circulatory variety, being due in many cases to surgical procedures, such as pulling on richly-innervated structures, during a condition of lowered blood-pressure, induced by chloroform-narcosis. These cases are not instances of chloroform-poisoning, the patient frequently being fully but not deeply under the anæsthetic, but of reflex inhibition of the medullary centres brought about by afferent impulses. The distinction is clearly shown by Crile's work, quoted by Dr. Hewitt. A good *resumé* of the subject of acid intoxication after anæsthetisation is also given, although the author himself has been fortunate in never having had a death from this cause. But though the question has only recently been brought into prominence, there is no reasonable doubt as to the actual occurrence of acetone-poisoning as an occasional sequel of anæsthetisation, at any rate with chloroform, and the possibility has to be borne in mind. The old features—the directions, the discussions, and descriptions—of Dr. Hewitt's book remain as good as ever, and the work is one of the standard authorities on its subject. It is noticeable that the author is styled "Physician-Anæsthetist to St. George's." Is this a sign of the times? If so, it is remarkable that while the obstretric physicians are becoming gynæcologists, physicians to the skin department, dermatologists, surgeons to the throat department—laryngologists, and so on, that the anæsthetist's nomenclature should be evolving in the opposite direction.

(a) "Anæsthetics and their Administration." By Frederick W. Hewitt, M.V.O., M.A., M.D.Cantab., Anæsthetist to His Majesty the King: Physician-Anæsthetist to St. George's Hospital, etc. Third edition, with illustrations. 15s. net. London: Macmillan and Co Ltd. 1907.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for The Medical Press and Circular.

RECENT SURGICAL LITERATURE.

Antitetanic Serum.—Terrier reports (*Revue de Chir.*, January, 1907) two cases of compound fracture in each of which the wound had been contaminated with earth and dung, and in which tetanus was feared, in each case 10 ccs. of antitetanic serum was injected within a few hours of the injury, in the first case seven days after the accident tetanus developed, the patient dying from it in three days; in the second case tetanus only developed eighty-seven days after the receipt of the injury, just as the wounds were healed up; this patient, after a protracted illness, recovered. These two cases show that one injection of 10 ccs. of the antitetanic serum is insufficient to prevent tetanus, though failure depends probably more on the state of the wound than on the amount of the injection. Septic wounds in which foreign bodies remain are specially favourable to the development of tetanus, hence the necessity for most careful cleansing of the wound. The writer recommends that in wounds suspected of being infected with tetanus, 10 ccs. of antitetanic serum should be at once injected beneath the skin, and a similar dose injected once a week until all danger of infection is over. The wound should be carefully cleansed and kept irrigated. In order to reach the lacerated nerve endings, though the toxin appears to enter the nerve sheath and so travel to the central nervous system, it is well to powder the wound itself with dry, pulverised antitetanic serum. G.

The Technique of Tendon Suture.—O. Frisch (*Wien. Klin. Woch.*, February, 1907). The best method of tendon suture is that introduced by Lange, called by him tendon weaving, beginning from the cut surface somewhat eccentrically, the needle and silk suture are passed in and out from one aspect of the tendon to the other over a length of several centimetres, it is then similarly returned down the other side and emerges parallel to its entrance, each thread is then woven up the other piece of tendon for a few centimetres, the ends are tightened and knotted. Great firmness is secured, as the strain is distributed over a considerable length of tendon, and the greatest strain is on that part furthest from the wound, and consequently in the soundest tissue. Exact adaption of the divided ends to one another is not difficult: there is only one knot, instead of several crowded together, an important point for the smooth working of the tendon. The suture is not easily loosened or extruded if local inflammation occurs, the firmness of this suture allows of early after-treatment, thereby adhesions are prevented. If several tendons are divided at about the same level, the sutures may be knotted alternately at the distal and proximal sides, so that the knots do not all lie together. As a gaping of the divided ends is no longer of consequence, the operation may be postponed until the danger that the wound was infected at the time of the accident has passed. The writer does not as a rule operate until after the fourth day. G.

Carcinoma of the Breast.—C. Ewald, in a note (*Zentralblatt fur Chir.*, April 6th) on the after treatment of cases of amputation of the female breast for carcinoma, calls attention to the difficulty many women experience after this operation in raising the arm on the operated side, sufficiently high to allow the hand to reach the back of the head, to get over this difficulty, the author has adopted the following plan with marked success:—As soon as the patient has recovered from the anæsthetic she is put sitting up in bed, to the head of the bed is attached an upright metal tube extending some three feet above the patient's head, it then bends at right angles, extending a similar distance beyond the side of the bed at which the affected arm lies. The patient's hand is now bandaged and straps pass from the hand, and are hooked on to the end of the bent metal rod, the supporting straps being of such a length that the arm is kept at right angles to the body. A second support is then passed under the patient's elbow and also attached to the metal head-piece; this makes the position easy and comfortable for the patient. The arm is kept in this position for three or four days, after this time it is let down several times during the day, until such time as the patient is allowed to leave bed altogether. In most cases by the end of the second week the woman was able to put her hand easily to the back of her head, and this without causing her any pain. Drainage of the axilla may have to be kept up rather longer than in ordinary, as the position of the arm makes it difficult to avoid leaving a cavity in the axilla which fills with either lymph or blood. In two years' experience of this method of after-treatment the author has had no bad results. G.

Rupture of the Colon Induced by Fæcal Impaction.—G. McCaskey records a case (*American Med.*, February, 1907) of a lady, æt. 42, who had for a long time suffered from constipation, and for some months past from severe pain in the region of the sigmoid, symptoms pointing to some obstruction, a laparotomy was done, but no narrowing of the bowel was found. This operation gave no relief, the pain continuing, and with this, violent peristaltic movements of the descending colon, small, hard fæcal masses came away from the rectum in the injections which were given daily, and the case was looked on as one of fæcal impaction. For two months her condition kept better; then suddenly one morning violent pain came on in the lower part of the abdomen, patient became collapsed, and died in three hours, there being no time to do an exploratory laparotomy. The *post mortem* examination showed a longitudinal tear extending from the upper part of the sigmoid up along the bowel for three inches; through this opening the colon contents had escaped into the abdomen causing intense peritonitis. A careful dissection of the colon below the tear showed a distinct narrowing of the lumen of the tube, amounting to a moderate stenosis, yet not sufficiently marked to allow of its being found during the previous operation. Above this obstruction was a hard fæcal mass, the rent had evidently been caused by the violent peristaltic movements of the bowel in trying to force this mass through the narrowed gut. There was no sign in the intestine of any induration or ulceration at the place where the bowel wall had given way; laceration probably occurred in connection with the direct and not with the reverse peristaltic contraction. G.

An Early Case of Formal Operation for the Separation of Jointed Twins (Xiphopagus).—Kieffe (*Med. Record*, April 6th, 1907) relates the history of a negro, æt. 66, which he has verified as being substantially correct. The patient's mother was captured and herded aboard a slaver for export to America. While in mid-ocean she fell in labour and suffered for nine days without being delivered. On the eighth day of her trial the slaver was seized by a Spanish corvette. On the following day the woman's condition was discovered, and the naval surgeon on board, José Brito y Boin, performed Cæsarian section, and removed a xiphopagus monster. Both were well-formed males and both were living. The mother died the same day. On the day of their birth the surgeon separated the two children. The patient's brother died in three days. One of the slave women acted as foster mother and reared the patient. The patient is at present under treatment for extensive keloid, which began in a scar over the sternum, marking the location of the fusing with his mate. When he was eight years old, in 1848, it had grown to such proportions that it was operated on and removed. The keloid reappeared in this locality, but never grew to be very thick. He has at present several other keloidal masses which appear to be becoming malignant. S.

Fracture Dislocation of the Spine.—Lloyd (*Medical Record*, March 23rd, 1907) points out that most fractures of the spine are fracture-dislocations. Fracture-dislocations resolve themselves into two classes: (1) Those in which the spinal cord is not injured, and (2) those in which there is more or less interference with the functions of the cord itself. For the first set of cases operative treatment would not be indicated in the beginning. The symptoms directly due to the fracture are those common to all fractures, but also the patient is unable to walk, and is markedly shocked. Local signs are usually unsatisfactory. When some slight irregularity of the spine is associated with marked tenderness on pressure—localised pain increased materially whenever the position of the patient is altered—or with fracture of the sternum, it is almost conclusive evidence of the localisation of fracture. The greatest care is necessary in making these examinations to avoid further injury. In these cases the author does not favour the application of plaster-of-Paris, unless there is marked mobility of the fragments, but thinks that the patient is better if placed in a horizontal position on his back, on a springless bed, and with sufficient extension and counter extension to compel him to remain in the dorsal position. Where there is marked mobility of the fragments, and it is difficult to keep the patient quiet, a plaster jacket should be applied. A much more complicated picture is presented when the spinal cord is involved. These cases are divided into three types: (1) Those in which the cord is crushed; (2) those in which doubt exists as to whether the cord is irremediably damaged; and (3) those in which it is fair to assume the cord is not irremediably damaged. Fracture of the spine with complete transverse lesion of the cord is accompanied by immediate relaxed motor paralysis involving the parts below the level of the lesion, with entire absence of rigidity, spasm, convulsive movements, or other irritative sign in the motor sphere. Partial injury to the cord, including the results of hæmorrhage, may be indicated by as lower onset of paralysis, by unilateral or irregular distribution, by the preservation, or comparative preservation of reflexes, and by rapid improvement. The author discusses operative treatment. If an operation be undertaken at once, there is danger of interference where a spontaneous recovery would result if the patient were left alone. If, however, operation is delayed too long, and a compression be allowed to continue a degeneration may result, which would be as serious as though the function of the cord had been destroyed by the original injury. In those cases where no improvement follows the recovery from shock, and yet a suspicion remains that there has not been complete crushing of the cord, operation should be immediately undertaken. Where the lesion of the cord is incomplete, and where symptoms of compression are extending, as evidenced by increased paralysis, etc., operation should be immediately directed to control hæmorrhage, inflammation thickening, or acute pressure, which are threatening to destroy the cord. In those cases where improvement is noted at first, but is arrested later, operation should be done as soon as it is settled that improvement has ceased. When paraplegia or other symptoms develop at a late date, after almost complete recovery under the usual conservative methods, this is probably due to the compression of callus and necessitates operative interference. It is essential, in order to secure success in operation to:—(1) To remove sufficient laminæ to absolutely settle the fact that there is no remaining compression of the cord; (2) to chisel off any projecting bone; (3) to remove all blood clots, whether extra-dural or intra-dural; (4) to look out for thickening and compression due to inflammatory processes. The author on two occasions of apparently complete transverse section of the cord, removed the pulpy mass and sutured the ends of the cord together. One patient lived three weeks, and the other ten months, but neither showed any signs of regeneration of the cord. S.

Gastroscopy.—Chevalier Jackson (*Medical Record*, April 6th, 1907) reports and illustrates eight additional cases (six cases having already been published) in which positive results have been obtained by his gastroscope. The author summarises the position of gastroscopy thus: (1) History: Gastroscopy has failed up to the present because no practical instrument has been devised. (2) Usefulness: It is useful for the detection and removal of foreign bodies in the stomach, the diagnosis of many pathological conditions, as inflammation, ulceration, scars, neoplasms, dilated vessels, and the treatment of at least one of these, namely, benign ulcer. It is a substitute for exploratory operation in many instances. (3) Results: The author has diagnosed by the gastroscope chronic gastritis 2, malignant disease of the cardia 2, of the pylorus 3, (in two of which a specimen was taken), peptic ulcers 5 (one of which was cured by direct applications). He removed a foreign body, and diagnosed gastric syphilis. (4) Limitations: Negative results are of limited value. (5) Anæsthesia by ether is preferable. (6) Dangers: In a patient with normal œsophagus and stomach the only danger is that of ether anæsthesia. An ulcer of œsophagus of stomach constitutes an exceedingly slight risk, unless the ulcer is on the point of perforation. In chronic inflammatory states no risk is incurred. (7) Any physician can learn to examine the stomach with a gastroscope. S.

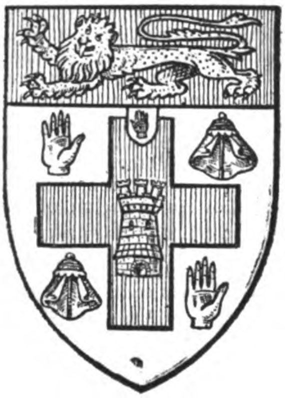
Enucleation under Local Anæsthesia.—On account of the possibility of the law of France being construed as holding a surgeon responsible for the death of his patient while under a general anæsthetic, unless its dangers have been explained beforehand, Terrien (*Arch. d'Ophthal.*, February, 1906) recommends the adoption of cocaine anæsthesia when possible. He has found it very suitable for the enucleating of the eye, and recommends the following method: A conjunctival anæsthesia is produced by two or three instillations of 4 per cent. cocaine or stovaine, adrenaline being used if the conjunctiva is inflamed. Over each rectus a sub-conjunctival injection of 1 in 150 is given, about 30 minims being used. At this stage, a hypodermic injection of morphia is made at some convenient spot. The conjunctiva and recti muscles having been gently divided, anæsthesia of the deeper parts is produced by injection of .5 c.c. of a solution of cocaine and morphine 01 each, stovaine and chloride of sodium each 02, sterilized water 5. Terrien uses an Anel's syringe with a blunt curved point for this last injection. After waiting some minutes the optic nerve may be divided and the operation finished. Cases of panophthalmitis are contra-indicated. M.

Dr. David B. C. Evans has been appointed resident assistant medical officer to Swansea Workhouse Infirmary.

Dr. Louis Corbett, Trinity College, has been appointed University lecturer in Pathology until Michaelmas, 1911.

Medical News in Brief.

Royal Augmentation to Shield of Arms.



In our last issue we referred briefly to the fact that the King had conferred upon Sir Frederick Treves and Sir Francis Laking the distinction of being permitted to use an augmentation of their arms, to which they are henceforth entitled to add one of the lions from the Royal Arms. Our readers will be interested to see that this honour is represented by the lion at the top of the shield.

Sudden Death of a Baronet under an Anæsthetic.

At Chelsea, on April 22nd, Mr. Luxmoore Drew held an inquest on the body of Sir Henry Leslie Huntington, who died at the Clock House, Chelsea, while under an anæsthetic. The deceased baronet was only 21 years of age. Sir Charles Huntington, the deceased's brother, who has now succeeded to the title, gave evidence of identification. Of late the deceased had good health, but he had grown too fast, though he was strong enough for field sports.—Dr. W. J. Frankish, of Sloane Street, said he would not call the deceased a strong man. He was 6ft. 3½in. in height, and was very much overgrown, especially of late years. The witness prepared him for the operation, and called in Dr. Hilliard to administer the anæsthetic. When the witness had made the first incision it was found that the deceased had stopped breathing and was changing colour. He, however, regained his colour and the breathing went on, but before the operation could be completed his pulse stopped, and the breathing became shallow. Artificial respiration was resorted to, but death occurred in a few minutes.—Dr. Spilsby, pathologist at St. Mary's Hospital, said that on making a post-mortem examination he found fatty degeneration of the walls of the heart with a little dilatation. That was a very unusual thing in the case of a young man. He also found enlarged abdominal glands, an enlarged spleen, and enlargement of the tonsils and lymphatic glands. The condition of deceased was known as status lymphaticus or lymphatism. That was a condition which had only recently engaged the attention of pathologists in this country, but was better known in Germany. It would not be recognisable during life, but persons subject to it seemed to be specially liable to sudden death from trivial causes. In this case death was due to syncope.—By the Coroner: Does this reveal a new danger in the administration of anæsthetics?—The Witness: Yes.—Dr. Hilliard was recalled, and said he had heard of the condition described by Dr. Spilsby, and if it were sufficiently marked to be noticeable in life of course an anæsthetic would not be administered.—The Coroner: But many people may be walking about with this condition undiscovered?—The Witness: Yes.—A verdict of death by misadventure was returned.

Famous Surgeon Drowned.

Scientific men in Austria are deeply grieved at the tragic death of Hofrath and University Professor Albert von Mosetig, one of the most prominent of Vienna surgeons. Professor von. Mosetig had not appeared for two days either at his house or at the hospital clinic under his direction. On April 26th, in the Danube meadows, some clothing was found, which was recognised as his, and witnesses say that on April 25th he jumped or fell into the water near the spot where the clothing was discovered. The cause of this sensational occurrence is enveloped in mystery. Professor von Mosetig made many discoveries in surgery, and his works are known to surgeons all over the world. In scientific circles he was known as having first employed iodoform in surgery.

Medical Treatment of Indian Women.

The annual meeting of supporters of the North India School of Medicine for Christian Women was held at Exeter Hall last week, Dr. J. L. Maxwell presiding. The committee reported that the Punjab Government had given a substantial grant, proportionate to the number of students, with an extra grant for students entering after passing a University entrance examination. Sir Charles Rivaz, the Lieutenant-Governor, had paid a visit of inspection to the school and hospital at Ludhiana; and the inspector-general of civil hospitals, Colonel Bate, had given valuable assistance. The principals of mission schools for girls were urged to help in supplying suitable students. Dr. Anna M. Fullerton reported that 46 out of 55 graduates were now actively engaged in medical work, 36 of them in connexion with 12 missionary societies.

Instructions in Military Medical Organisation.

In consequence of the success which, in the West of London, attended the movement for initiating the formation of an organised Army Medical Civilian Reserve, it is proposed to hold another class this summer. The instruction will be given by specially experienced officers of the Royal Army Medical Corps at a convenient place for medical men residing in the metropolis. The importance of this class is increased by the certainty that trained civilian medical co-operation will have to form a part of the organisation of the new "Territorial Army." Gentlemen desirous of joining this class are requested to send in their names to the acting Hon. Secretary, Mr. Herbert Chambers, 101, Goldhawk Road, London, W.

Effects on Health by the Adulteration of Wines and Spirits

An important conference was held in London on Monday last at the Institute of Hygiene, of medical men and others interested in the suppression of adulteration. Sir Wm. Bennett, K.C.V.O., F.R.C.S., presided and remarked that although opinions were divided as to the necessity of alcoholic beverages, there could be no question that when used they should be pure. Dr. Fredk. J. Smith proposed that "the adulteration, substitution, and misrepresentation of wines, spirits, and beer affects the health and strength of the people, especially in connection with its tendency to induce a craving for drink, and that the Local Government Board, licensing and other authorities, be called upon to take such steps as are necessary to prohibit the sale of liquors which are not what they profess to be and the medical profession be appealed to, to exert their influence to prevent their consumption." This resolution was seconded by Dr. Wm. Ewart and carried unanimously. Several further resolutions of a similar character, especially in regard to so-called medicated wines, were also passed, and it was decided to submit the same to the Prime Minister and to the President of the Local Government Board.

The Nutrient Value of Plasmon.

In an action brought last week by the International Plasmon Syndicate against MacSymons, Limited, to recover damages for alleged libel, Dr. Robt. Hutchison, the well-known authority on food and dietetics, stated in evidence that he had analysed Plasmon, and had found it most nutritious and sustaining. Considering what Plasmon was, he could not conceive that it could be anything else than health sustaining, containing as it did a large proportion of protein, which was a tissue-forming substance. Dr. Passmore, confirming this view, said that he had been acquainted with Plasmon as a food since 1899. It was all made out of milk. A pound of Plasmon contained as much nutrition as 27 pints of milk, and as much protein as a half-pound of steak. Ultimately the jury returned a verdict for the plaintiffs with damages £100 and costs.

PASS LISTS.

Royal College of Physicians of London.

The following candidates, having passed the final examination in medicine, surgery, and midwifery of the Examining Board in England, the Licence of the Royal College of Physicians of London has been conferred upon them, viz.:—George H. Adam, Frederick O. Arnold, B.A.Cantab., Hugh T. Ashby, B.A.Cantab., Philip H. Bahr, B.A.Cantab., Harold J. Beddow, B.A.Cantab., Richard C. P. Berryman, John Birch, Robert E. Brayne, Robert D. Brown, Josiah Browne, Charles W. G. Bryan, Martin B. S. Button, L.S.A., Harry V. Byatt, B.A.Cantab., William J. Chapman, M.D., C.M.Toronto, Percy, J. Chissell, Spencer Churchill, B.A.Cantab., Edward B. Clayton, B.A.Cantab., Horace C. Colyer, L.D.S.Eng., Percival S. Connellan, Paul A. Creux, Timothy H. Davies, Arthur H. T. Davis, Herbert E. T. Dawes, B.A.Cantab., George Denholm, M.B., B.S.Durham, Arnold T. Densham, Horace Dimock, B.A.Cantab., Maurice M. Earle, Howard R. Elliott, Carlton A. Ellis, William A. Fairclough, M.B., Ch.B., John H. Farbston, Marmaduke Fawkes, Norman Flower, B.A.Oxon, William E. L. Fowler, Claude H. S. Frankau, William D. Frew, L.D.S.Eng., Percy C. Garrett, Harold Gibson, William S. Gibson, L.S.F., Alexander S. Graham, George Graham, B.A.Cantab., William R. Greening, Frederic W. W. Griffin, B.A.Cantab., Robert E. V. Hale, B.A. Cantab., H. McCormick Hanschell, Robert N. Hartley, Lionel C. Hayes, Arthur W. Hayward, Charles E. K. Herapath, George A. F. Heyworth, B.A.Cantab., Walter de Marchot Hill, Hendrik Houwink, Henry O. Howitt, M.D., C.M. Richard de Silva Illesinghe, L.M., Charles G. Jarvis, M.D.Paris, Richard S. Jenkins, William G. Jones, L.D.S., Alexander J. Kendrew, Solomon Krestin, M.D., B.Sc., Malcolm Leekie, Harold H. Leeson, William S. Leicester, B.A.Cantab., Richard L. Ley, B.A.Cantab., Conrad Loddiges, William Lovell, L.S.A., Frederick B. Lowe, M.R.C.V.S., James B. Macalpine, M.B., Ch.B., Colin F. F. McDowall, M.B., B.S.Durham, Charles G. McGreer, M.D., Eric L. Marchant, M.B., Ch.B., William B. Martin, John H. Mayston, Brian B. Metcalfe, Henry L. Morgan, Edgar L. R. Norton, Henry S. Ollerhead, Arthur O'Neill, Gerard L. Parsons, Basil T. Parsons-Smith, Walter Patey, Stanley Paulin, M.B., Charles Pemberton, Edward C. Pope, Otto C. W. Prausnitz, M.D., Geoffrey Price, John L. Rankine, John A. Renshaw, Kenneth Robinson, Cecil F. Rumsey, L.D.S.Eng., Alfred L. Sachs, M.A.Cantab., Leslie St. Vincent-Welch, John Selfe, Edgar A. Shirvell, Arthur L. Singer, William F. Skinner, L.S.A., Francis G. Snoad, Edward C. Sparrow, B.A.Cantab., Lionel D. Stamp, Frank Standish, George Stone, Arthur A. Straton, Joseph R. Sutherland, M.B., Ch.B.Glasgow. Ronald E. Todd, Sohrab S. Vazifdar, L.M., Charles E. Waldron, John L. Walker, M.D., C.M., Norman H. Walker, B.A.Cantab., Harry G. Webb, Henry B. Weir, B.A.Cantab., Harrie B. Wickham, Joseph W. J. Willcox, Cecil L. Williamson, Lorton A. Wilson.

The Royal University of Ireland.

The following candidates have passed the M.B., B.Ch., B.A.O. Degrees Examination:—

Upper Pass.—Charles R. Harvey, Rowland Hill, B.A., John J. Kearney, Victor J. McAllister, Richard V. Slattery, B.A., O'Connell Sullivan, John P. Waters, B.A.

Pass.—James Barrett, John W. Beirne, John A. Boyd, Daniel Boylar, George F. Campbell, Nicholas M. Donnelly, Francis T. Dowling, B.A., Jane M. Fulton, William McKee, Charlotte E. Mitchell, Jerome B. Murphy, B.A., Joseph Nunan, Patrick O'Hart.

The following candidates may present themselves for the further examination for Honours in the groups set after their names:—Charles R. Harvey (Medicine, Surgery, Midwifery), Rowland Hill, B.A. (Medicine, Midwifery), John J. Kearney (Medicine), Victor J. McAllister (Medicine, Surgery, Midwifery), Richard V. Slattery, B.A. (Surgery), O'Connell Sullivan (Surgery).

The M.D. Degree Examination.—Robert J. Bethune, M.B., B.Ch., B.A.O., Michael J. O'Flynn, M.B., B.Ch., B.A.O., Henry E. S. Richards, M.B., B.Ch., B.A.O.

The M.Ch. Degree Examination.—Cecil B. F. Tivy, M.B., B.Ch., B.A.O.

The following candidates have passed the Second Examination in Medicine:—

Upper Pass.—*James Byrne, John Cullen, *Arthur V. J. Harrison, William S. Haydock, *Henry C Malcolm, *Walter Mooney, B.A., David V. S. Willis Those marked with an asterisk may present themselves for the further examination for Honours.

Pass.—James S. Bellas, Patrick J. Campbell, John J. Dennehy, Blanche G. C. Griffin, Michael J. Hackett, Jeremiah Holland, Thomas H. Houston, George E. Hull, Melville C. Irwin, John L. Jackson, Barkley McCullough, B.A., Patrick McGinnis, Thomas C. McMurray, Patrick J. Mockles, Henry C. Mulholland, Arthur F. N. Mullane, Patrick F. Murphy. Michael J. O'Connor, William H. O'Grady, William F. O'Regan, William Prendwille, Thomas W. Ruttledge, Walter Stevenson, Robert W. Vint, John F. Walsh, Hill W. White, Timothy Woulfe.

Percy M. J. Brett is exempt from further examination in Anatomy and Physiology.

The Stewart Scholarship in Medicine has been awarded to William W. D. Thomson, Queen's College, Belfast.

Cambridge University.

Dr. Barclay Smith has been appointed to examine in human anatomy for medical degrees for the remainder of the year, ending November 1, vice Mr. A. Macalister, who is unable to examine.

The following candidates have satisfied the examiners in both parts of the sanitary science examination:—E. J. Brown, J. B. Cook, Catherine Fraser, F. H. G. Hutchinson, D. C. Kirkhope, C. H. Lindsay, D. McKail, P. Mackessack, J. S. New, W. G. Parker, J. C. Robertson, J. B. Smith, A. N. Stevens, F. E. Stokes, and T. M. Strang.

Royal College of Surgeons in Ireland.

A Meeting of Fellows will be held on Tuesday, May 7th, at 4.30 p.m., pursuant to the provisions of the Supplemental Charter, for the Election of Examiners.

"Graduates of any University which may be from time to time recognised by the College shall be eligible for election as Examiners in the subjects of General Education. All the other Examiners shall be Fellows or Licentiates of the College, or Professors or Lecturers in any School of Medicine recognised by the College. Persons engaged in private teaching are not eligible to be Examiners."

Conjoint Examinations in Ireland.

The following candidates have passed the Second Professional Examination of the Royal College of Physicians and the Royal College of Surgeons, held during April, 1907:—

H. Gray (with Honours), A. M. T. Blake, A. G. Bennett, J. P. Egan, J. M. Gage, H. Hunt, T. Murray, J. T. O'Boyle, J. J. O'Connor, J. G. O'Mahony, J. Patton.

Royal Colleges of Physicians and Surgeons, Ireland.

The following candidates have passed the Third Professional Examination:—A. L. Clarke, B. W Farrell, J. Farrell, J. P. Grainger, C. Greer (Victoria Australia), J. Humphreys, C. Macauley, J. C. Murray M. Power, M. J. Saunders, A. Sheridan, C. Stringer.

Society of Apothecaries of London.

The following candidates, having passed the necessary examinations, have received the L.S.A. diploma of the Society entitling them to practise medicine, surgery, and midwifery:—H. A. Fenton, C. S. Spencer, F. A. K. Stuart, and W. V. P. Teague.

NOTICES TO CORRESPONDENTS, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

Binder.—There are several common varieties of domestic fly. The chief are *musca*—the common house-fly; *Bucentes Ceneoubatus*, a blood-sucking fly, commonly found in the house; the stable fly, which is bred in dung—especially in stables—and bites man and horses. It too is frequently found in the house.

PASSING OF THE MEDICAL PROHIBITION BILL.

This measure, the object of which is to stop derelicts of the profession from joining commercial companies which persistently evade the Medical and Dental Acts, passed the second reading in the House of Lords on Monday night.

Serum.—One of the earliest, if not the very earliest, attempt to provide scientific instruction for the people was that made at Manchester in 1866, when Sir Henry Roscoe, Dr. T. Alcock, Professor Stanley Jevons, and Dr. J. E. Morgan gave a series of evening lectures on Chemistry, Zoology, and Physiology. Upwards of 4,000 people attended these courses, a charge of a penny being made for admission. The audiences were composed of people of the class for whom the lectures were designed, and the attention given is described as having been remarkable.

M.B., Ch.B.—Certainly it is possible to treat congenital phimosis without operation. The difficulty in drawing back the prepuce is due to adhesions of the contiguous mucous surfaces. Frequently these can be broken down by a probe gradually inserted and worked round between the prepuce and glands. Great care must be taken not to enter the meatus. After repeating the process several times at short intervals, the prepuce can generally be drawn back, and the need for the operation consequently vanishes.

Mr. J. Baer is thanked for his note on Cerebro-Spinal Meningitis. So far as we are aware Professor Symmers is the first to have succeeded in the cultivation of "the meningo-coccus for many generations." The serum of the Berne Bacteriological Institute, is well-known and appreciated in this country.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MAY 1st.

Obstetrical Society of London (20 Hanover Square, W.).—8 p.m.: Specimens will be shown by Mr. J. Bland-Sutton, Dr. Lewers, Dr. M. Thorne, and Dr. Lowgridge. Short Communication:—Dr. C. R. Porter (introduced by Dr. R. Andrews): Case of Fatal Rupture of the Bladder during Labour. Paper:—Dr. A. Doran: A Case of Malignant Vaginal Polypus Secondary to an Adrenal Tumour of the Kidney.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. A. H. Tubby: Clinique. (Surgical). 5.15 p.m.:—Lecture:—Dr. P. Stewart: Migraine.

North-East London Post-Graduate College (Tottenham Hospital, N.).—Cliniques:—2.30 p.m.: Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Out-patient (Dr. Whipham).

THURSDAY, MAY 2nd.

North-East London Clinical Society (Tottenham Hospital N.).—4 p.m.: Discussion on the Use of Posture in Surgical Treatment (opened by Mr. H. W. Carson).

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. E. Clarke: The Fundus Oculi in Health and Disease (with lantern slides).

North-East London Post-Graduate College (Tottenham Hospital, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques: Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson). 3 p.m.: Medical In-patient (Dr. Chappel).

FRIDAY. MAY 3rd.

Society for the Study of Disease in Children (11 Chandos Street. Cavendish Square, W.).—5 p.m.: Clinical Evening for the Exhibition of Cases, followed by Discussion. Patients in attendance at 4.30 p.m.

Epidemiological Society (11 Chandos Street, Cavendish Square, W.).—8.30 p.m.: Paper:—Dr. A. K. Chalmers: Some Recent Manifestations of Cerebro-spinal Meningitis.

West Kent Medico-Chirurgical Society (Royal Kent Dispensary).—Presidential Address:—Mr. C. J. Heath: The Duty and Power of Restoring the Hearing when Operating for Chronic Suppuration of the Middle Ear.

Laryngological Society of London (20 Hanover Square, W.).—5 p.m.: Exhibition of Cases and Specimens.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. B. Harman: Clinique. (Eye.).

North-East London Post-Graduate College (Tottenham Hospital, N.).—9.30 a.m.: Clinique. Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. Leslie).

Vacancies.

Wandsworth Union Infirmary, St. John's Hill, near Clapham Junction.—A Male Junior Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

Lewes Dispensary and Infirmary and Victoria Hospital.—Resident Medical Officer. Salary £120 per annum, furnished apartments, board, coal, gas, washing, and attendance. Applications to the Hon. Secretary.

Berry Wood Asylum, Northampton.—Junior Assistant Medical Officer. Salary £150 per annum, with board, lodging, washing, and attendance. Applications to the Medical Superintendent.

West Bromwich District Hospital.—House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to Honorary Secretary T. Foley Bache, Esq., Churchill House, West Bromwich.

Rochdale Infirmary.—House Surgeon. Salary £100 per annum, with board, residence, and laundry. Applications to the Hon. Sec., R. W. Shaw, Esq., Moss House, Rochdale.

Camberwell.—Parish of St. Giles.—Assistant Medical Officer at their Infirmary, Brunswick Square, Camberwell. Salary £120 per annum, with apartments, board, and washing. Applications to Charles S. Stevens, Clerk to the Guardians, Guardians' Offices, 29 Peckham Road, S.E.

Cuninghame Combination Poor-house, Ayrshire.—Medical Superintendent. Salary £300 per annum, with house, fuel, light, vegetables, and laundry work. Applications to Wm. Gray, Secretary, 5, Montgomerie Street, Ardrossan.

North Stafferdshire Infirmary and Eye Hospital, Hartshill, Stoke-on-Trent.—House Physician. Salary £100 per annum, with furnished apartments, board, and washing. Applications to the Secretary and House Governor.

Alnwick Infirmary.—House Surgeon. Salary £120 per annum, with furnished apartments, attendance, coals, and gas. Applications to Wm. T. Hindmarsh, Honorary Secretary of the Alnwick Infirmary, 26 Bondgate Without, Alnwick.

Bradford Children's Hospital.—House Surgeon.—Salary £100 per annum. Applications to C. V. Woodcock, Secretary.

Johannesburg Hospital.—House Physician and House Surgeon. Salary £300 per annum, with board and lodging. Applications to Ronald P. Mackenzie, M.B., C.M., D.P.H., Superintendent, Johannesburg Hospital, Johannesburg.

West Riding Asylum, Wadsley, near Sheffield.—Fifth Assistant Medical Officer. Salary £140 per annum, with board, &c. Applications to the Medical Superintendent.

Appointments.

Briscoe, James R., M.R.C.S., L.R.C.P.Lond., Junior House Surgeon at the Great Northern Central Hospital.

Brown, A. Carnarvon, M.R.C.S., L.R.C.P.Lond., Senior House Surgeon at the Great Northern Central Hospital.

Doble, F. Carminow, M.R.C.S., L.R.C.P.Lond, Junior House Surgeon at the Great Northern Central Hospital.

Faulder, T. Jefferson, M.A., M.B., B.C.Cantab., F.R.C.P.Eng., Honorary Assistant Surgeon to the Throat Hospital, Golden Square, W.

Gunn, R. M., M.B., B.S.Aberd., Senior House Physician at the Great Northern Central Hospital.

Hutchinson, F. A. Stewart, M.D., B.C.Cantab., M.R.C.S., L.R.C.P. Lond., Honorary Assistant Surgeon to the Sussex Eye Hospital Brighton.

Lavington, Cyril C., M.B., B.S.Durh., Out-patient Physician to the Bristol Royal Hospital for Sick Children and Women.

Matheson, R. Murdoch, M.D.Edin., F.R.C.S., Clinical Assistant to the Royal Victoria Hospital for Consumption, Edinburgh.

Milburn, Oscar, M.R.C.S., L.R.C.P.Lond., Junior House Physician at the Great Northern Central Hospital.

Parsons, George Gooden, L.R.C.P.Lond., M.R.C.S., L.S.A., Medical Officer for the Workhouse of the Westbury and Whorswelldown (Wiltshire) Union.

Stevenson, Howard, M.B., B.Ch.R.U.I., F.R.C.S.Irel., Assistant to the Professor of Surgery, Queen's College, Belfast.

Births.

Barnes.—On April 26th, at 455 Mansfield Road, Sherwood, Nottingham, the wife of R. G. Barnes, L.R.C.P., L.R.C.S.Ed., L.F.P.S. Glasg., of a daughter.

Cox.—On April 24th, at Anderton, near Plymouth, the wife of H. P. Cox, M.R.C.S., L.R.C.P., of a daughter.

Crabtree.—On April 13th, at Furneux Pelham, Herts, the wife of E. F. Crabtree, M.R.C.S., L.R.C.P., of a daughter.

Gaman.—On April 26th, at Caistor House, Caistor, Lincolnshire, the wife of F. R. S. Gaman, M.R.C.S., L.R.C.P., of a daughter.

Sedgwick.—On April 23rd, at 95 Richmond Road, Kingston-on-Thames, the wife of H. R. Sedgwick, M.B., B.C., of a son.

Wilgress.—On April 24th, at 45 Cheriton Road, Folkestone, the wife of J. H. F. Wilgress, M.B., B.C., of a daughter.

Marriages.

Craigie—Monkhouse.—On April 25th, at St. Bartholomew's Church, Bobbing, Kent, the Rev. John Alexander Craigie, M.A., son of the late John Craigie, Esq., M.D., C.B., to Mary Eleanor Maria Monkhouse, daughter of the late William Thomas Monkhouse, Esq.

Fernie—Harding.—On April 24th, at St. Mary's Church, Stafford John Firth, third son of Edward Fernie, M.D., of Stone, Staffs., to Catherine Middleton, eldest daughter of John Harding, Stone, Staffs.

Hazell—Dalgleish.—On April 27th, at St. George's Cathedral, Capetown, Frederick Hazell, M.R.C.S., L.R.C.P.Lond., to Edith Haynes, third daughter of the late William Dalgleish, of South Hampstead.

Death.

Wilson.—On April 26th, at Denham House, Goldhawk Road, London, Enid May, youngest daughter of James Wilson, M.D., aged two years.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIV. WEDNESDAY, MAY 8, 1907. No. 19

NOTES AND COMMENTS.

Imperialism and Medicine. THE visit of the Colonial Premiers has naturally re-awakened that sentiment of affection for the Colonies which as a rule slumbers so heavily that some occurrence out of the ordinary is needed to bring it to activity. All parties in the State are united in the pleasure of welcoming the representatives of their kinsfolk, and each tries not to obtrude its politics too much lest it should hurt the feelings of the other. But it is inevitable that the words "Empire" and "Imperial" should be on everybody's lips, whatever may be the precise meaning implied by the different persons using them. It has struck some folk that as the British Medical Association is applying for a Charter, this would be a happy moment to change its name from the domestic one by which it is known to the high-sounding designation of the "Imperial Medical Association." Indeed, the advocates have not confined their arguments to their medical brethren, but have even overflowed into the ordinary daily journals to find sympathy with their proposal. If their desire in changing the name be to please the colonists, we fancy that they are mistaken, as the colonist feels his proudest title and nearest link with the old country coincides with the word "Britisher," and anything more at variance with the spirit of medicine, which is catholic, cosmopolitan, and world-wide, than to introduce any idea of imperial exclusiveness, it is difficult to conceive. Medical men of course have their own individual political views and aspirations, but the spirit of medicine is quite apart from and vastly superior to the passing political phases of the moment, and in its common and indiscriminating regard for all, irrespective of nationality, birth, or wealth, medicine should be quite untrammelled by imperial or national associations.

Cerebo-Spinal Fever and Secrecy. A CURIOUS statement, attributed to Dr. Gordon, has been widely circulated during the last few days, namely, that a new treatment for cerebro-spinal fever had been discovered, but that it is of a "confidential nature." This he is reported to have said in evidence before the Belfast Health Commission, and the remark was followed by an offer to put some of the substance, which appears to be a bacterial derivative, at the disposal of the health authorities in that town, if they care to give it a trial. Now in this world it does not do to be as harmless as a dove without being at the same time as wise as a serpent, and we can imagine what misunderstandings are likely to be raised by interested parties if it goes forth to the world that some secret serum, vaccine, or other "pestilential juice" is being injected into the veins of the innocent children of Belfast. Moreover, the idea of any secret remedy being used for treatment is against the traditions of the profession and, if the health authorities are to use this method of treatment, the nature of what exactly they are employing should be revealed to them and their *confrères*.

Vaccination Bill. WE suppose it is impossible to grumble at Mr. John Burns' new Bill substituting a statutory declaration of conscientious belief that vaccination would be harmful to the child's health, for the present personal appearance of the parent before a magistrate. When the conscientious objector was first brought on to the stage, Mr. Balfour purposely made his progress a little difficult in order that the merely idle or careless parent might not take advantage of the privilege in order to save himself trouble in nursing or looking after the child. The conscientious objector was admittedly an impossible person to argue with or to convince, and the easiest administrative method of getting rid of him was thought to lie in giving him his way without more ado than was absolutely necessary. But the magistracy throughout the country, stirred to righteous indignation against the perversity of these individuals, have made their path as thorny as possible, and by so doing have certainly done vaccination an ill turn, for they have given the grievance something to feed on, and have kept alive the spirit of discontent; whereas had the certificate been granted with business-like despatch the anti-vaccinationists would have had no cause to grumble. It is now pretty clear that the action of the magistrates was a mistake, and the new Bill is the natural sequence of it. But the temptation to evade primary vaccination will now be correspondingly greater.

Paying the Substitute. AN extraordinary case involving the interests of a medical man was tried towards the end of last month in the South Shields County Court. The guardians of that place employed as medical officer to one of their districts, Dr. Drummond, who had held the position for twenty-five years. Last year they suspended him from duty because his assistant, a qualified man recognised by the Local Government Board, had seen a larger proportion of the patients than usual, the reason for which was that there happened to be a number of cases of sickness in the vicinity of his (the assistant's) house. Dr. Drummond appealed to the Local Government Board, who very properly ordered the guardians to reinstate him, which of course they were bound to do. Now during the period of suspension, the guardians had employed another doctor whom they paid at twice Dr. Drummond's rate of salary, and when the latter was reinstated they actually had the effrontery to deduct half the amount payable to him towards the expense of this compulsory substitute. He therefore brought an action against them for the return of the sum, and for once in a way the judge gave the clerk who appeared for the guardians a smart dressing-down. He asked if the defence seriously put forward as the reason why they refused to pay the plea that Dr. Drummond had not fulfilled the duties which they would not allow him to fulfil, and characterised it as a "most extraordinary idea." Finally, he gave judgment for the plaintiff with a special order as to costs and counsel's fee. In this case at least we may congratulate Judge O'Connor on perspicacity and good sense.

Tests for Drunkenness.

WHEN giving evidence before the Police Commission last week, Mr. Plowden, in recounting the difficulties of a police magistrate's life, said that many of his troubles would be relieved if medical men would agree on some common sign of drunkenness. We pity Mr. Plowden from our hearts, but he must know well enough that the difficulty is not with the medical men but with the law. It is impossible to frame a law that will define what degree of alcoholic intoxication amounts to punishable drunkenness, and the evidence of drunkenness must rest entirely on a medical man's judgment. All poisons are variable and affect different persons differently, and every "test" for drunkenness from "British Constitution" to "toeing the line" is only *ballona d'essai* at the best, and is liable to be vehemently disputed by the defence. Magistrates would find the complexity of their task in such cases considerably lightened if they discarded the shibboleth of tests and relied on the testimony of an experienced police-surgeon. The reproach, let us repeat, is with the law and not with medicine.

LEADING ARTICLE.

MR. HAFFKINE AND THE INDIAN GOVERNMENT.

THE British Empire, which sways the destinies of a great proportion of the population of the world, is naturally vexed with many problems arising from the complexity of conditions existing among her Crown colonies and dependencies. The results are seen on every hand in the grotesque and often incongruous patchwork of laws and of administration that figures under our flag both at home and abroad. A limited Parliamentary franchise in the United Kingdom, for instance, stands side by side with adult suffrage in New South Wales. The jealously guarded civic magistracy of our insular system, again, stands out in vivid contrast from the wide and autocratic powers vested in Indian magistrates, who as a rule combine civil with military functions. Of all incongruities, however, there is perhaps no single one more apparent than that involved in public health. The value and sacredness of man's life have attained such an exalted place in the estimation of our modern humane Government, that the occurrence of a few extra deaths from enteric fever in any Little Peddlington village is followed by official investigation and report from the Local Government Board. On the other hand, in India, with its two hundred and ninety millions of inhabitants, the Government appears to view with resigned indifference deaths from a purely preventable disease like plague at the rate of many thousands a week. Professor Ronald Ross states that in the nine years up to the end of 1905, more than 4,000,000 deaths from bubonic plague occurred in our Indian Dependency, and quite recently Professor Simpson said that 20,000 deaths were occurring weekly from the same cause. These facts constitute a severe indictment against British sanitary rule in India. Dr. Ronald Ross, at any rate, does not blink matters in his recent letters to *The Times* about Mr. Haffkine's prophylactic serum and the Mulkowal disaster. He maintains that the whole story of the plague in India in recent years illustrates the disregard for science that often stamps British administration. Though plague had been raging in Hong Kong for two years before the outbreak in Bombay, the Indian authorities nevertheless appear to have organised no system of sanitary intelligence, to have investigated few of the cases, and to have equipped themselves with no adequate bacteriological and other indispensable preventive machinery. History has taught us that this disease, which for centuries devastated Europe, can be ousted by the influences of an average standard of sanitation. The great plague of London never recurred, because the contributory precedent conditions were not reproduced after the Fire of London. In modern times the whole question has been brought under the control of science by the isolation of the specific bacillus by Kitasato and Yersin during the Chinese epidemic of 1894. The supreme outcome of a curative serum has not so far reached us from the medical bacteriologists, in whose hands the future conquest of disease to a great extent unquestionably rests. On the other hand, the immunisation of persons who have been exposed to the infection in a plague-stricken district has been given to the world by the brilliant researches of Haffkine. There can be no question as to the prophylactic efficacy of his sterilised bouillon culture of the *bacillus pestis*. India has reason to be proud of

Haffkine, who in this particular matter of the prophylactic serum has proved himself worthy of a place among the great benefactors of the human race. For all that, he has been called upon to face the whips and scorns of fierce contemporary criticism, because, forsooth, one of his serum bottles was contaminated by tetanus bacillus, probably long after it had left his laboratory, and a handful of deaths from lockjaw ensued. The Indian Government, whose incompetent sloth and indifference had led to 4,000,000 preventable deaths, appear to have left Haffkine, the one man in all the world who has shown the way to scientific salvation, to public reprobation. Rather should the Government have erected statues of brass throughout India in honour of his great achievement. It is not the way of British Administration, however, to bestow recognition of that kind upon civilians, especially in India, where military methods reign supreme. The authorities in that country have still to learn that disease must be fought by scientific men and not by soldiers. The results of their mistaken policy are writ large in the terrible mortality from preventable disease that has always drained the life-blood of British population, civil and military, in that great dependency. It is recorded in more lurid characters in the millions of natives that are sacrificed year by year to visitations of a similar kind. Some day, possibly, the British Government will adopt a wiser and more humane view of their responsibilities towards the bodily welfare of the people who are subject to our rule. Meanwhile, we may safely trust the Secretary of State for India to take efficient steps for the protection of Mr. Haffkine and for the furtherance of his prophylactic work. In this hope we are strengthened by the recollection that Mr. John Morley is himself a medical man, and it is mainly to that profession that we must look for the ultimate banishment of plague, pestilence, and disease generally from off the face of the earth. The life-work of men of the stamp of Haffkine will do much to hasten the day of that most desirable millenium.

CURRENT TOPICS.

King Edward's Hospital Fund Bill.

It is with extreme regret that we notice that the Council of King Edward's Hospital Fund are pushing forward their Bill for incorporation in spite of the general feeling of disapproval expressed by the profession through its organs. The Fund aims at becoming absolutely autocratic and irresponsible, even more so than it is at present, whereas such a body should essentially be representative of subscribers, hospital authorities, and the medical profession. The powers sought are at variance with every principle valued by a free and democratic country, and the most unhappy part of all is that this authority is to be vested in the Prince of Wales, who will thereby incur all the odium which action by the Fund may excite at any time. The proposed constitution is the last that should be sought, and the Prince of Wales is the last person who should have been chosen to be the responsible officer under such a constitution. The Royal Family should be kept strictly out of all controversial matters and should never be made, even in appearance, the stalking-horse of individual interests. The present Bill has been passed through the House of Lords up to its third reading, and is being taken as an unopposed measure. We hope some sturdy Commoner may be found to oppose it when it goes to the Lower House, as the Bill jeopardises not only all the hospital interests of London, but is liable to bring the Prince of Wales, through his benevolence, to occupy an invidious position. The subject was fully dealt with in the Medical Press and Circular of January 23rd last.

Domestic Compensation and Hospital Patients.

The advent of the extension of workmen's compensation to domestic service raises many points with regard to medical practice. So far as the general practitioner is concerned, we have already advised him to fix a uniform fee to be charged for all consultations involving compensation claims, whether to the master or servant. Medical men in hospitals, both of the salaried and of the honorary staff, will be wise to form some plan of dealing with these cases. Otherwise the medical profession will find itself taken advantage of on all sides by solicitors and their clients who wish to get medical evidence free. Hospital authorities, and hospital residents, too, will do well to make up their minds that under no circumstances will information as to the nature of accidents or sickness be given in compensation cases without adequate fees. In point of fact, the proper course would be to exercise the rights of a medical witness in Court, and to demand prepayment of fees before giving any evidence whatever. Without such precaution those who give evidence in cases which are settled out of Court will run the risk of getting no fees at all. In important cases an endeavour will doubtless be made to secure the testimony of the assistant or full honorary surgeons or physicians, who doubtless will demand fees as expert witnesses.

The Proposed Registration of Plumbers.

The proposal to register plumbers compulsorily has been before the public for some time. It has been actively advanced in London by the wealthy and powerful City Company of the Plumbers, who naturally wish to resume and extend their authority over the trade in question. There is much to be said on both sides of the matter, and it would be well for all concerned to inform themselves of the various issues involved before committing themselves to any scheme of the kind. The Edinburgh Public Health Committee recently declined an invitation from the Worshipful Company of Plumbers of London asking the Corporation to authorise a representative to take part in a proposed deputation to the Local Government Board "with the object of seeking recognition and support in securing the

Should Medical Men have a Day of Rest?

Possibly one of the wisest of the world's dispensations has been that which provides man with a seventh-day rest. Prehistoric man in all likelihood first learned the lesson, since crystallised in the famous classic phrase which intimates that even Achilles cannot always stretch his bow. Of all sorts and conditions of men, members of the medical profession come nearest to that impossible feat, for they work early and late, week in and week out. Nor is there any possibility of the State coming to their aid with an Eight Hours Bill, unless, indeed, it would be possible at the same time similarly to restrain within a time limit the matronly labours whereby the population is recruited to an average and a progressive level. Of all classes that minister to the welfare of mankind, the medical man deserves most tender consideration, for the health not to say the lives of the community lies in the hollow of his hand. As things go, he is for the most part overworked and underpaid; he is exposed to the unfair competition of quacks and quackery of all kinds, notwithstanding that the State has compelled him to undergo a long and costly education, and after granting him a licence to practise, fences him in with a thousand-and-one iron-bound regulations. Most medical practitioners make some sort of a living, but few stumble on fortune, and the general experience is that of the old song, inasmuch as "they work all day for too little pay." There can be little doubt that if anyone deserves a Sunday rest it is the hard-working medical practitioner. In some parts of the Continent, the profession has agreed to nominate a weekly batch of their brethren for Sunday duty, while the others enjoy a well-earned rest. Last week in Paris the proposition was seriously discussed whether a double fee should not be charged for Sunday visits. That practice is already unofficially in vogue in some parts of the United Kingdom, nor is it easy to see how it could be at all strenuously opposed by a community that recognised the necessity of maintaining a proper standard of health and energy among their medical attendants. Granted some plan for dealing with pressing sickness and emergencies, there is no clear reason why medical men should not have, at any rate, an occasional Sunday to themselves.

Practice by Companies.

The reception in the House of Lords of Lord Hylton's Bill for the Prohibition of Medical Practice by Companies, was distinctly encouraging, and we hope that the Earl of Crewe's statement of the views of the Government may be taken as forecasting the granting of facilities for getting the Bill through the Lower House. As he put it, the Bill is designed to meet what nearly approaches a public scandal. By a defect in the law it has been possible for those who could not individually practise as physicians or surgeons, to obtain freedom so to do simply by registering themselves as a company. If the Bill pass into law this evasion will be prevented, and the formation of companies for the purpose of medical practice will be prohibited. As Lord Crewe explained, the measure is somewhat drastic, prohibiting all medical practice by companies, even where the company would employ legally-qualified practitioners to carry on the practice. His lordship's remarks showed a proper appreciation of the personal relations subsisting betewen medical man and patient, and of the desire of the better class of medical men that such personal relations should continue. We trust that every exertion will be used to pass into law Lord Hylton's Bill, as well as the similar measure prohibiting dental practice by companies.

PERSONAL.

H. R. H. the Prince of Wales has graciously consented to take the chair at the dinner of the National Association for the establishment of sanatoria for workers suffering from tuberculosis, to be held on Tuesday, May 14th, at the Hotel Cecil, London.

At a meeting of Barry Parish Council, on April 26th, the resignation of Dr. Paton, who had held the office of medical officer for the northern district of the parish for the long period of thirty-one years, was submitted and accepted.

Dr. Archibald, the assistant medical officer of Glasgow, who contracted cerebro-spinal meningitis, is making progress, and it is now confidently expected that he will make a good recovery.

Three lectures on the pre-historic and early historic inhabitants of England will be delivered before the Royal College of Surgeons of England on May 6th, 8th, and 10th at 5 p.m., by Mr. William Wright, M.B., D.Sc., F.R.C.S.

Dr. Frederick Taylor has been elected a representative of the Royal College of Physicians of London on the Senate of the University of London in place of Dr. W. H. Allchen, whose term of office has expired.

From Paris the death is announced of Dr. Paul Poirier, the well-known surgeon. Dr. Poirier was Professor of Anatomy at the Faculté of Paris.

Inspector-General H. M. Ellis, Director-General of the Navy Medical Department, has been unanimously appointed first President of the newly-formed "United Services Medical Society," to which reference is made in our "News" column of present issue.

Dr. Frederick Taylor has been unanimously appointed consulting physician to Guy's Hospital on his retirement from the acting staff. Dr. Lauriston E. Shaw is promoted to fill the physiciancy, and Dr. A. F. Hertz has been appointed an assistant physician.

Dr. M. J. McQuoid, of Ballyjamesduff, has been appointed to the Commission of the Peace for the County of Cavan.

The Wightman Lectures of the Society for the Study of Disease in Children, will be delivered on Friday, May 17th, in the rooms of the Medical Society of London, at 5 p.m., by Dr. Frederick Taylor, the subject being "Pneumonia in Children."

During the past fortnight seventy-one cases of epidemic cerebro-spinal meningitis have been notified in Glasgow as against eighty-one in the previous two weeks, while the deaths have fallen from sixty-three to fifty-nine.

A CLINICAL LECTURE
ON
THE USE AND ABUSE OF SKIAGRAPHY IN FRACTURES AND DISLOCATIONS. (a)

By JOHN POLAND, F.R.C.S.Eng.,

Senior Surgeon to the City Orthopædic Hospital, London; Senior Surgeon to the Miller Hospital, Greenwich.

One is often asked whether skiagraphy has afforded us generally a clearer knowledge of fractures, a better diagnosis, and, consequently, better and more efficient methods of treatment. To each and all of these questions I can unhesitatingly answer in the affirmative, provided that a proper and scientific observation has been made.

I hope to be able in this lecture to point out some of the uses and abuses of this method of diagnosis.

Without the increased experience in technique which we now possess, and with the many abuses with which the earlier days of the Röntgen process was beset, and which I am sorry to say too often still exist, the use of skiagraphy must assuredly be more harmful than useful. Any practitioner can set up an X-ray apparatus with a Crookes' tube and fluroscope, and use it. But there will always be a field for an X-ray specialist who can always be available and competent in the use of the X-rays for every class of case beside fracture—one who has a wide knowledge of anatomy and is skilful in the proper interpretation of skiagrams. Such a person must necessarily be a qualified medical man. It is monstrous to suppose that all this can be efficiently performed by an unqualified chemist. Yet everywhere we still see advertised in chemist's shops, hydropathic establishments, at instrument makers, and in other places that an X-ray apparatus is on the premises and available for their customers. The abuse of powerful apparatus in hands such as these will be apparent to you all. Yet medical men are not blameless in this matter; they still send their cases to chemists, instrument makers, &c.

I strongly advocated this view of the matter many years ago—soon after the Röntgen method was first used. At that time I was asked the following questions, among others, as to the establishment of an X-ray department in the hospital of a very large and important provincial town:—

1. Should not the hospital have the apparatus necessary to apply the Röntgen rays to the patients therein, many of whom are men engaged in large works in the district and who constantly meet with accidents?
2. Can an ordinary medical man in the borough properly use it?
3. What is the cost of a first-rate apparatus?
4. If the medical man cannot use the apparatus, can a competent photographer use it?

What, I replied, was: *First*, In short, that a photographer was certainly incompetent as was also an electrician, unless the latter was under the supervision of a medical man, and did only the manual or operative work; and *Second*, That there were always excellent medical men in every district who could readily acquire the proper technique, and that a post for the medical man should be created at the institution, which was especially one for the diagnosis and treatment of fractures and other injuries and urgent cases. I think you will agree with me that these replies hold equally good at the present day.

In the first place, as to the use of the X-rays in *Clinical Diagnosis*. Fractures are no longer—or should no longer be—mistaken for dislocations, sprains, or severe contusions, and *vice versa*, although pain and swelling exist in all these conditions. However, Lynn Thomas (*British Medical Journal*, May 5th, 1906) has given us some startling limitations of the usefulness of the X-rays, especially with regard to the treatment of fractures. In his opinion the rays are of no value in modifying the ordinary methods, and to form a correct diagnosis they are, in nearly all cases, unnecessary. One is almost persuaded on reading the conclusions he draws up that it is a great misfortune that the rays were ever discovered, at any rate, so far as these injuries which we are considering to-day are concerned. He only admits that in a few cases they may be of value in clearing up a doubtful point, but says, "the evidence afforded by X-rays is deceptive, misleading, and should only be submitted to and acted upon by those who understand their value." To the last part of the paragraph all must agree; but with regard to his other conclusions, I cannot imagine that he has many sympathisers.

I am sure that the Röntgen method has established a clearer and more extended scope in our diagnosis, and, as a consequence, our methods of treatment are daily becoming much more definite, less severe, less complicated, although it must be admitted that they are rendered wider in range and more exacting on the care and attention of the surgeon; indeed, already in many instances our methods of treatment have become most exact and perfect and are carried out with great precision.

Mere palpation, although most serviceable in detecting the various signs of fracture or dislocation, cannot—even when combined with large experience—do now, and could not do in the past what we now accomplish with the assistance of the X-rays. Skiagraphy must be employed in fractures by every conscientious and careful surgeon, however great may be his skill in diagnosing these lesions by the older methods. I cannot do better than repeat what I stated in 1901:—"The use of the X-rays does not supersede the ordinary methods of clinical diagnosis; it supplements them in a most valuable way, especially where great swelling of the soft parts exists. It makes the presence of a fracture clear where otherwise doubt might exist." It is now common knowledge that many fractures of the carpus, phalanges, metatarsus, and elbow joint were almost entirely unknown before Röntgen's discovery.

INTERPRETATION OF SKIAGRAPHS.

All of us as surgeons are quite cognisant of the normal characteristics of bones and joints as seen by the naked eye, but it is quite another thing in interpretating skiagraphs, where we have to consider only shadows. These shadows are often printed as a permanent record of the shortcomings of the surgeon, but this I will allude to later on. These shadows can be distorted to any extent, and will vary according to the distance of the sensitized plate from the bones and according to the position of the tube. Take the hip joint, for instance. If the tube be placed below the joint, the shadow of the neck of the femur will give the appearance of considerable deformity, whilst the pelvis itself appears to be considerably distorted.

The shadow of a bone is an entirely different thing from a photograph or from the naked eye appearance of the same bone. Therefore the interpretation of shadow is unquestionably more difficult than that of a photograph. If we could always compare the shadow of a normal bone in the same position as that of an abnormal shadow of an injured bone, our task would be lighter; but, unfortunately, no one has yet attempted a complete skiagraphic atlas of the whole body. Probably the task is too immense for any individual worker. To render the interpretation of skiagraphs easy, and to avoid as much as possible distortion of the parts, Mr. Chisholm Williams has suggested the following points :—

(a) Delivered at the Medical Graduates' College and Polyclinic, Wednesday, March 20th, 1907.

1. That there should be certain points on the human subject over which the anode should be placed, and that on the skiagraph a small mark should denote the position of the anode.

2. That the distance from the tube to the plate or film should never be less than 18 inches.

3. That in the lower extremities they should be placed at a right angle with a line drawn between the two anterior superior spines, and that the spine be absolutely at right angles to this also. In the case of one hip joint being fixed in, say, adduction, then the sound limb should be placed at a right angle.

4. In the upper limbs, for the shoulder-joint the arm should make with the mid-line an angle of 45°, and the hand rest with the palmar surface downwards. The opposite sound parts should always be shown for comparison, taken, of course, under exactly the same conditions. In the elbow-joint the internal condyle being on the film, the anode should be placed over a point about an inch below the external condyle in the line of the forearm. This is for the purpose of opening up the joint as much as possible.

5. For the trunk, it should be placed as symmetrical as possible, and in the case of the neck vertebræ I have found the best position is with the occiput well over the end of the film or plate, and the chin high up, exactly in a straight line with the sternal notch.

Now what are the conditions where we find the X-rays of great importance? I would enumerate them as follows :—(1) Sprains. (2) Fractures accompanied with great swelling. (3) Fractures and dislocations about joints. (4) Fracture with great displacement. (5) Separations of the epiphyses. (6) Ununited fractures.

Take first of all that large class of injuries called *Sprains*, which were formerly regarded as a laceration of a ligament of a joint or other soft tissue. We now know by the X-rays that these usually comprise a detachment of a small fragment of bone. Indeed, a large number of sprains should be classed under the heading of fractures, and, of course, have appropriate treatment. I maintain that, fracture of a small portion of bone being so often co-existent with sprain, all cases of sprain should be examined by the X-rays. How often in the past has the complication of fracture in sprains been undetected on account of the absence of the supposed characteristic sign of crepitus? Very often the complication of fracture is only revealed some time after the receipt of the injury and its treatment by the doctor, the patient consulting some non-medical radiographer to the discomfiture of the surgeon.

In sprains of the phalanges of the finger, this undetected complication is very frequent.

A French surgeon has lately discovered by means of the X-rays that a fracture of one or other of the smaller metatarsal bones occur in soldiers on the march. The injuries had been previously considered as sprains.

The value of the X-rays where *Immense Contusion and Swelling* from rupture of superficial vessels leading to complete obliteration of every bony prominence, is very great. A complete and satisfactory examination by palpation in such cases is quite impossible. One good instance of this occurred in the early days of the X-ray. A young man had fallen off his horse and injured his elbow. An eminent surgeon who was called in by the doctor to see the case was quite unable to make a diagnosis, and rather discountenanced the use of the rays. However, the practitioner on his own responsibility took an X-ray picture, which revealed a complete dislocation backwards of both bones at the elbow. An anæsthetic was at once given and the dislocation reduced with a most favourable result.

In the case of fracture the very fact of severe contusion and swelling might, as of yore, tempt the surgeon to make attempts at reduction and cause displacement where none existed, were it not for the knowledge obtained by the X-rays. The X-rays, having no consideration for any amount of swelling, reveal the simple condition of affairs in the injured bone and instruct us that no manipulations are necessary, and a simple splint or dressing is applied.

The study of *Injuries to the Epiphyses* in children and youths entails an accurate knowledge of the normal ossification of the bones as seen by the naked eye; but also more especially of ossification as seen by the X-rays. As regards the ossification of the hand, I have endeavoured by my "Skiagraphic Atlas of the Hand and Wrist" to give a complete account of this latter process.

In the early days of the Röntgen era, the non-recognition of the unossified or partially-ossified epiphyses failing to produce a shadow, led to many deplorable mistakes.

I hope not to be thought egotistical when I state that I was the first (in February, 1906) after the introduction of the X-rays in this country, to point out the importance of skiagraphy as an aid to the diagnosis of epiphysial lesions in children. I then described and figured (*British Medical Journal*, March 7th, 1906), the case of a boy, æt. 17, where the X-ray photograph confirmed the diagnosis of a separation of the distal epiphysis of the metacarpel bone of the index finger. I also drew attention to the great importance of obtaining skiagraphs of certain forms of recent complicated injuries to the epiphyses in children.

You will agree with me that my remarks over eleven years ago, were justified, and that we are now fast gaining this knowledge of these important injuries.

However, there is a very important class of injuries in which skiagraphy does not help us; in fact, the negative findings of this method of examination may lead to disastrous results. I allude to *Epiphyseal Separations without Displacement.* I have drawn attention to it elsewhere.

Common situations of this form of injury exist at the lower end of the radius, and lower end of the femur. I show you a skiagram of one of these latter injuries in which backward displacement of the femoral epiphysis has subsequently taken place. The absence of diagnosis and consequent neglect of treatment are liable to be followed by arrest of growth of the bone. This absence of treatment I have shown to be the most frequent cause of interference with the proper growth at the epiphyseal junction.

TREATMENT OF FRACTURES.

Accurate apposition of the fragments being the most serious item in the treatment of fractures, the X-rays give us the greatest assistance. The bringing of the fragments of the bones into apposition under the X-rays in recent fractures is an important step. In this way the surgeon can see as well as feel whether the bones are in position. It is only, however, in a few situations that this method can be satisfactorily employed, because of the difficulty in carrying the patient to the X-ray department with all the necessary apparatus for fixation of the fragments. At the shoulder, elbow, and wrist this method is particularly useful. The Röntgen process cannot, however, always determine the *cause* of the displacement or rotation of the fragments of the bone, although it often gives us valuable points in the display of comminution of fragments of the broken ends, or of the rotation of one or other fragment or rotation of a separated epiphysis. It cannot show us the hindrance to reduction, through muscular spasm, or the interposition of muscle, periosteum, or other soft structure between the fragments. Still, recently, with improved technique, these interposed tissues have been detected in some instances.

If the interposed material be a small portion of bone, the method, of course, is of value.

All fractures should be taken by the X-rays after being "set." The stereoscopic method should, if possible, be always employed. Indeed, this method is becoming quite popular, and will be more so in the future, more especially as the requisite extra apparatus is very inexpensive.

It is easy to watch the position of the fragments and to rectify it, if malplaced, as far as possible during the process of consolidation.

Even after an operation on the bones, as well as before, I may here remind you that a little overlapping of the fragments may look very bad in skiagrams. Such skiagrams have been produced in the Law Courts as evidence of want of skilful treatment. The overlapping frequently does not affect the functional result in the least, so that perfect functional results may be obtained, although the findings of the skiagraphs in no way agree with this.

In malposition of the fragments in *old fractures*, the Röntgen rays enable us to make a complete diagnosis of the anatomical conditions and to work out our operative measures exactly. This method is especially useful in deformed oblique fractures of the femur and at the malleoli of the ankle, where, in the latter, we are able to resect a wedge from the diaphyseal ends and correct the deformity.

Passing now to a few of the *Medico-Legal aspects* of the Röntgen method. In a fracture in the neighbourhood of a joint the displacement may be slight, and the practitioner look upon the injury as not particularly severe; but the X-rays would have shown him that the fracture is really intra-articular or comminuted—a very different condition from the patient's point of view. Contrast this with another case of simple fracture with displacement further away from the articulation, which may be easily reduced and rapidly get well without untoward result. The patient would contrast the adverse results in the first case, supposing the intra-articular lesion undetected by the X-rays, with the favourable result in his neighbour's case treated by another practitioner, and we see the beginning of much criticism on his part.

So many skiagraphs have lately been produced and admitted in evidence in Courts of Law in suits for damages after accidents and in cases of malpractice, that I should like to add my protest against the custom as it obtains at present. The Southern *v.* Lynn Thomas and Skyrme case last year was a case in point. The skiagraphs in that case showed that even under most favourable conditions some overlapping of the fragments very frequently persists, but that this faulty position in very many respects does not interfere with the ultimate results in a strong and functionally useful limb. Fortunately in this country we have not had the frequent charges of malpractice or claims for damages in Courts of Law which occur in the United States of America and on the Continent. Yet these actions at law, based, upon the abuse, as I must call it, of the X-rays, have become sources of annoyance and financial loss to surgeons. There are some solicitors only too ready to act in collusion with X-ray offices conducted by electricians or photographers or others.

The remedy is in the hands of the surgeons, as I have hinted at the beginning of my lecture. The X-rays may show a fracture when none exists, or fail to show a fracture which is clearly manifest by clinical signs. This latter is rare except, as I have mentioned above, in epiphyseal separations. Again, the deformity from a fracture may easily be exaggerated to an enormous extent. It is also well to remember that in recent fractures in which union has taken place with formation of good callus, the condition presented is often indistinguishable from that of non-union of a fracture on account of the non-deposition as yet of the lime salts.

I am not one of those who entirely question the advisability of admission of skiagraphs into a Court of Law. I do not consider it right to say that skiagraphs are inaccurate; they are perfectly accurate if they have been taken under the superintendence of the surgeon, and taken and considered in combination with the clinical signs present.

The improper use of skiagraphs in Court is quite another matter. No surgeon should be asked in Court (or, indeed, out of Court) to pass an opinion on an X-ray picture without an examination of the patient taken at the time of the picture and without the guidance of an accurate interpretation of the same.

In concluding these general remarks I would emphasise the fact that, especially as regards deformity, skiagraphs by themselves without surgical interpretation and, moreover, taken under proper conditions, and considered with the clinical signs, are absolutely of no value—indeed, must often be positively misleading.

I would, in conclusion, briefly point out how great is the value of skiagraphy in regard to *injuries in various joints and bones*, as it has presented itself to me during the past eleven years (*a*). I am positive that the ideal method of diagnosis is, that every care should be submitted to the X-rays, whether uncertainty as to diagnosis exists or not, and that the Röntgen process should be used as a scientific adjunct to clinical methods and in no other way.

Many apparently simple cases display some comminution, obliquity, or rotation, and *vice versa* an apparently severe fracture with great swelling and contusion will turn out to be a very simple one through the co-operation of Röntgen's process. But each case should be made a complete study in itself.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Professor Alfred J. Smith, M.B., M.Ch., F.R.C.S.I., Gynæcologist to St. Vincent's Hospital, Dublin, Examiner in Midwifery, Royal University of Ireland. Subject: "Climateric Floodings."*

ORIGINAL PAPERS.

A CASE OF

ULCERATIVE COLITIS—APPENDICOSTOMY—CÆCOSTOMY—COMPLETE RECOVERY. (*b*)

UNDER THE CARE OF

ARTHUR LATHAM, M.D.Oxon., F.R.C.P.Lond.,
Physician to St. George's Hospital.

AND

FRANCIS JAFFREY, F.R.C.S.Eng.,
Surgeon to St. George's Hospital.

On March 10th, 1906, Edward O., æt. 48, was admitted to St. George's Hospital with a history of passing mucus and blood from the bowel daily since the beginning of February. The bowels had acted several times a day from the commencement of the illness and in each motion blood and mucus was present. Gradually the number of motions passed a day had increased until the bowels were opened as often as sixteen times in the twenty-four hours. In many instances the motion consisted of pure blood. On February 25th, there

---

(*a*) The lecturer then set forth the utility of skiagraphy in individual joints and bones and presented in illustration of this a large number of skiagraphs from his own practice.

(*b*) Read before the Harveian Society of London, April 18th, 1907.

was a definite rigor, which was followed by much debility together with fever to the extent of 103° F. for a few days.

There had been no previous illness, and the man had always been temperate.

On admission.—The man was obviously very ill, being markedly anæmic, and drowsy. The temperature was normal; the pulse 100, of low tension; the tongue dry and dirty. There was some tenderness in the right iliac fossa, but no rigidity or abnormal dulness in the abdominal area. On examination of the rectum by the finger no marked tenderness or other abnormality was discovered. On examination with the sigmoidoscope no ulceration of the rectum or pelvic colon could be seen.

The stools were frequent, ten, fourteen, sixteen in the twenty-four hours. They consisted chiefly of blood mixed with a little mucus and pus.

The patient was kept absolutely at rest, in bed, on a light spare fluid diet. Various drugs by the mouth, such as calcium chloride, opium, liquor ferri pernitratis, tannalbin, were given without effect. The colon was washed out daily by large injections of boracic acid (ʒi to a pint) and later by injections of silver nitrate (10 grs. to two pints) without effect. Starch and opium and other enemata were given with the hope of controlling the hæmorrhage, but failed to diminish this symptom.

As the man was in a precarious condition, Mr. Jaffrey was asked to perform appendicostomy, so that the bowel might be flushed out more thoroughly.

Operation, March 30.—Mr. Jaffrey operated by the incision used for the removal of the appendix. The appendix was small, and a partial division of its mesentery was necessary before it could be brought out of the wound, and stitched to the abdominal wall. It was not opened until the following day, when the protruding portion was removed. It was found impossible to pass any catheter, even a probe, through the lumen of the appendix owing to swelling of its walls; however, a few days later the swelling having subsided, a No. 5 olivary was passed and some saline solution was injected into the cæcum. Owing to the small size of the appendix, it was impossible to irrigate the colon properly, and the condition of the gut did not improve. There was no diminution in the amount of blood, mucus and pus passed or in the number of times the bowels acted. On further consultation with Dr. Latham it was decided to remove the appendix and perform a cæcostomy.

On May 5th, Mr. Jaffrey opened the scar of the former wound, removed the appendix, and sewed the cæcum to the abdominal wall, but did not open it till the following day. When the cæcum was opened it was seen that the mucous membrane was very much thickened and that the slightest touch caused it to bleed. It was now freely irrigated each day by means of a fountain syringe from a height of three feet above the patient, with a pint to two pints of a solution of listerine of a strength of 1 oz. to a pint of water. Occasionally adrenalin of a strength of ʒi to the pint of water, or Liq. hammameledis ʒii to the pint was used with the hope of lessening the amount of blood passed. The result of this treatment was truly wonderful, for in less than a fortnight practically all the symptoms had disappeared, and there was no blood, mucus or pus, in the stools. It was also noticed that the thickened mucous membrane had very nearly returned to its natural thickness.

After a few days of this treatment the patient was given ordinary diet, together with cod-liver oil and malt; and a quinine and strychnine mixture was prescribed. He rapidly regained flesh and was anxious that the cæcum should be closed. The closing of the opening in the cæcum was, however, delayed as it was thought that possibly the colitis would return when the man resumed his ordinary way of living. A colotomy belt was ordered and the patient was sent to the Atkinson Morley Convalescent Hospital at Wimbledon on June 13. He remained there a very short time, as the fluid fæces caused a troublesome irritation around the colotomy wound. He returned to St. George's Hospital. The eczematous condition was intractable at first, but yielded to the application of boracic acid mixed with lanoline. An attempt to close the opening in the cæcum was made on September 18th. This was not completely successful as slight discharge of fæcal matter continued. On a second attempt on October 9th, the wound healed finally, and the patient returned to his work and has remained in good health since. He has had no further symptoms of colitis.

Remarks by Dr. Latham and Mr. Jaffrey.

This case shows the beneficial results of prompt resort to the performance of cæcostomy when medicinal measures have failed in the treatment of ulcerative colitis. No doubt the fact that complete rest was given to the colon through the operation of cæcostomy being performed within three months of the initial symptoms accounts to some degree for the rapid recovery. There can be little doubt that if the colon had not been opened the patient would have rapidly succumbed to the disease. There are several points of interest in the case. The condition of the cæcum suggested acute inflammation of the mucous and muscular coats, and although no ulceration was seen, yet hæmorrhage followed on the slightest manipulation. The fact that pus was present in nearly every motion shows that definite ulceration must have been present in the colon. The inflamed condition of the colon entirely subsided within ten days of the opening of the cæcum, and the tendency of its mucous membranes to bleed ceased within six days of the operation.

The operation of appendicostomy for the purpose of allowing the bowel to be flushed out failed entirely. It was performed in view of the favourable reports given by various operators of this procedure in the treatment of colitis. In this case the swollen condition of the appendix prevented the passage of a fine probe. Even in an healthy appendix the lumen will seldom allow the passage of a catheter larger than a No. 10. Flushing out of the bowel by means of a No. 10 catheter cannot be so effectual as flushing out by means of a large-sized glass nozzle after cæcostomy, and this may account in part for the fact that when appendicostomy is performed, flushing of the bowel has not infrequently to be continued for many months. Another advantage of cæcostomy over appendicostomy in cases of colitis is that by its means real rest is obtained for the diseased colon. The fact that the closure of the colotomy within four months of the operation was possible may in part have depended on the fact that the case was not of long standing. In closing the cæcum it is necessary to first wash out the bowel just before operating and to pare the edges of the wound with great care.

EPITHELIOMA INVOLVING THE HEAD AND FACE WITH GREAT DESTRUCTION OF TISSUE.

By Professor JOHN P. SHOEMAKER, M.D., LL.D.

Professor of Skin and Venereal Diseases in the Medico-Chir. College and Hospital, Physician to the Philadelphia Hospital for Diseases of the Skin.

The patient, Mr. R. B——, æt. 47, born in the United States, came under my observation three months ago. He is fairly intelligent, and gave the following history: He stated that eleven years ago, a small, hard, indurated pimple appeared on the helix of the left ear. It annoyed him to some extent by a constant itching pain, which caused more or less scratching. The effect of this was to cause the lesion to become sore and bleed. This condition was always followed by a tendency to ulceration, which on healing formed a scab. Every time the scab came away the ulceration would become more marked. This state continued for three years without much variation His physician at this time advised him to have the spot removed, because he thought it to be an epithelioma. This the patient refused to do and consulted a "cancer doctor," who applied a caustic paste or salve which removed the spot or ulceration with a portion of the ear as well. The wound produced by the application of the caustic paste did not heal, but ulcerated more decidedly, and gradually "ate," as he expressed it, the entire ear away. After the ear was destroyed, more caustic paste was applied to remove the infiltration, supposed to be cancerous skin. The second application removed not only the skin but also large masses of the underlying tissues.

The ulcer was now over two inches in diameter, and the disease was over six years standing. Gradually the ulceration spread, the eye became involved, and was finally removed. Two years ago X-ray treatment was instituted, but it was of no avail. The patient stated that the ulceration continued and to-day it involves the entire half of the head, giving the patient a most horrible deformed appearance, part of the lip being destroyed, so one can look right into the mouth and throat.

His family history is entirely negative. As a child he had measles, varicella, whooping cough, diphtheria, and mumps, and influenza fifteen years ago. He is married, but has no children. His habits have always been good; he never used either tobacco or alcoholic liquors. The patient is greatly emaciated, but otherwise presents no abnormal physical signs. Even the glands of the neck are not enlarged. He is nervous and very irritable, which is due to the fact that he is unable to sleep without a hypnotic or anodyne. The pain is worse from eight to twelve o'clock at night. I made the diagnosis of epithelioma from the history, the age of the patient, and the appearance of the ulcers, which involves the entire half of the head and face, including the mouth. The edges of the ulcer are sloping, indurated and slightly elevated. The base is reddish, granular, and covered with a viscid yellowish secretion. The ulcer bleeds easily, is painful, and for the past year has been increasing in size very rapidly.

No microscopic examination of the tissue could be made, as even at this late date the patient will not permit a specimen of the tissue to be removed under any circumstances. I had great difficulty in inducing him to permit either a history or his photograph to be taken.

The present ulceration has the appearance of what has been described as a rodent ulcer, but the bone or even the periosteum is not involved. Some of the deeper muscles are likewise not involved, consequently the diagnosis of rodent ulcer is ruled out.

A differential diagnosis lies between lupus vulgaris and epithelioma; my opinion inclines decidedly to the latter. The following table will briefly show the difference of the two diseases:

Epithelioma.	*Lupus vulgaris.*
1. Develops after 35 years.	1. Develops before puberty.
2. Lesion, a single papule.	2. Lesion, multiple, gelatinous tubercles or papules.
3. Ulcer is deep with sloping edges and surrounding skin is infiltrated.	3. Ulcers superficial and sharply defined, no inflammatory areola.
4. Secretion is viscid and scanty.	4. Secretion usually abundant, yellow, and purulent.
5. Pain is a marked feature.	5. Pain usually absent or very slight.

It is only fair to suppose that the immense slough, in the absence of enlarged lymphatic glands and other symptoms usually present, is entirely due to the caustic action of the "cancer plasters or pastes" that were applied. The composition of most of the so-called "cancer plasters" employed by the "cancer doctors" is nothing more than the old Vienna paste, with or without arsenic. The escharotic and destructive action of such caustics is well known to every physician who employs them even with the greatest care and caution. In truth in many of the cancers and especially in epithelioma the ulcerative and destructive action of the malignant growth may be increased by the application of the caustic agent or agents, and such is particularly the case after the application of arsenic. Again, in employing arsenic over a large surface the systemic action of the drug often develops. I have had several cases in the hospital in the past few years which presented marked systemic arsenic poisoning due to the local application of the drug to ulcers and malignant growths. In these instances the applications were usually made by the quack or so-called "cancer doctor" who applies one of the many pastes or plasters to draw out, as they say, the cancer by the roots.

In one patient the poisonous action from the arsenic was so severe as to jeopardise the patient's life for many days.

The application of the X-rays to some of the malignant growths, especially if pushed too rapidly or too severely, will often produce a most destructive action and increase the disease instead of ameliorating it, as in one case that I have had and which I propose to report, where the molecular destruction was so great that it resulted in sepsis followed by death.

FRIEDREICH'S ATAXIA. (a)

By FREDERICK S. PALMER, M.D., M.R.C.P., Lond.,

Physician to the West-End Hospital for Diseases of the Nervous System.

The disorder, which bears the name of the distinguished Professor, formerly at the head of the Heidelberg School, from whence so many eminent physicians and scientists have come, was first recognised by Friedreich in 1861.

Historical note.—(1) At the Congress of German naturalists and physicians, held at Spire, (the ancient cathedral city and capital of the Rhine Palatinate, in Bavaria), on September 18th in that year, he presented (and afterwards published the notes of) six cases of ataxy in the members of two families, presumably running on lines of consanguinity, whose symptoms-complex did not conform to the masterly description of locomotor ataxia given by Duchenne, of Boulogne, in 1858–9. From a careful study of these cases, Friedreich believed they belonged to the same group, but there were special points in their clinical history which had been overlooked in Duchenne's account of the malady. For several years afterwards, in France, under the influence of the teaching of Charcot, Vulpian, Bournville and Guerard, cases of ataxie héréditaire were regarded as one of the irregular types of insular sclerosis—a disease at that time attracting a great deal of attention—the main facts recorded by Friedreich were either ignored or lost sight of. (2) The next case reported was one by Carre, in 1865, and, after a pause of nearly six years, Bradbury published another, and Carpenter two, of evidently the same class, in 1871. These were followed by two cases reported by Kellog in 1875, three by Dreschfield in 1876, and three more by Friedreich in 1877, making nine of his series. Eleven other cases were recorded by Kahler and Pick, Schmidt, Seeligmüller, Hollis, Gowers and Fraser in 1880. At the end of that year the total number of cases reported was only thirty-one. (3) In August, 1882, Marie wrote a memoir in competition for a resident hospital appointment, in which he collected the various facts recorded by authors, and the results of his own observations on the subject, describing the disorder, like all the other writers, as a form of tabes. Auguste Brousse, of Montpelier, inspired by Grasset, in an excellent thesis published the same year, first claimed for the disease a separate entity, and proposed to bestow on the malady, the name of the distinguished observer, by which it is now so commonly known. This thesis may be said to mark the second stage of progress, in the evolution of our knowledge of the disease. Two years later (1884) the first case was recognised in Paris. A young lad was brought to Charcot at the Salpêtrière by a physician attached to the hospitals, deeply interested in the progress of medical science, as a probable example of juvenile tabes—a clinical condition then, much in dispute. Before submitting his diagnostic acumen to the searching criticism of a learned society, he desired with praiseworthy modesty, to have his opinion confirmed by that eminent neurologist. Marie, who was then acting as a clinical assistant at the Salpêtrière, relates in his thirtieth lecture, how Charcot at once detected the nature of the disease the boy was suffering from, rescued his confrère from the probable, and humiliating consequences of an unfortunate conclusion, and a few days afterwards, devoted a lecture to the consideration of the special features of the case, which definitely established the separate existence of Friedreich's ataxy.

Since then, a number of valuable, and important contributions have been made to the literature, notably the writings of Rütimeyer, Musso, Massalongo, Gilles de là Tourette, Blocq, and Huet, Letulle and Vaquez, Crozer Griffith, Dana, Marinesco, Achard and Weigart Dejerine, the remarkable thesis of Soca, published in 1888, and the valuable contributions to *Brain* of Everitt Smith, Ormerod, Mackie Whyte and Ladame, of Geneva.

At the present time, the disorder which Friedreich discovered, constitutes an accepted, and well-defined malady, and its position in the nosography of nervous diseases is due unquestionably to the thesis of Brousse, written under the influence of Grasset, and to Charcot's lecture delivered in 1884. It is essential, as Osler remarks, that in speaking of this (4) affection, its prominent symptom, ataxy should be expressed, to avoid any confusion, with another clinical condition, paramyoclonus-multiplex or myoclonia, described by Friedreich twenty years later, in 1881, which has a strong resemblance to Henoch's chorea electrica, sometimes called lightning spasms, and is occasionally spoken of as Friedreich's disease.

Definition.—A disease occurring usually in several members of a family during the developmental epochs, characterised by ataxy, wide spread paresis, impairment of speech, nystagmus, deformities and other less constant symptoms.

The co-existence of the disorder in more than one member of the same family and its common appearance in childhood, or at puberty, stamps it as one of the so-called familial type, and clearly points to its origin in some inherited morbid developmental tendency. In both these respects the affection in question presents a striking analogy to the group known as the muscular dystrophies or myopathies.

Isolated cases are undoubtedly encountered, and many have now been reported, especially in small families, but these sporadic examples. are open, as Soca admits, to the argument, that if the number of children were greater, more might have suffered from the disorder. Although it is not an uncommon circumstance to find three, four or even five brothers and sisters affected consecutively with the disease, it is absolutely certain, that the others who are not so afflicted, may remain in perfect health.

Ætiology.—(5) Strümpell asserts that the disease is rarely seen "in members of the same family in different generations," but there is little, if any doubt, that heredity in the broad sense of the term, is the prime factor in Friedreich's ataxia. (6) It has been traced through several, as many as four generations in one family. (7) Ten cases in three generations of a single family have been reported. The family proclivity was strongly insisted on by Friedreich, who appreciated its importance, and the prominent position it occupies as a distinguishing feature of the malady.

Predisposing causes.—Apart from the question of direct or indirect inheritance, the following are believed to exercise predispositional influences.

1. Neurotic diseases in ancestors, or collaterals.
2. Alcoholism in the parents.
3. Syphilis in the parents.
4. Consanguinity in the parents.
5. Over-production, prolonged lactation and disparity of age in the parents.

The part which a neuropathic inheritance plays in the history of all nervous disorders, is too well known to require any comment.

Intemperance—In the ancestry, as a probable factor in hereditary ataxia, was suggested by Friedreich, who attached considerable weight to it. In his first series of six cases in two families, both of the fathers were habitual drunkards, and one of the mothers after the death of her husband remarked, "the children were conceived in drunkenness."

Evidence of syphilitic transmission has been rarely traced, and there are few facts recorded to support the connection. The children of tabetic parents seldom, if ever, present the symptoms of Friedreich's ataxia.

Consanguinity, according to Gowers, appears sometimes to intensify the morbid tendency. Two families have came under my notice within the last four years afflicted with this scourge, and in both instances the parents were first cousins. The unhappy results, certainly as regards nervous and mental diseases which so frequently follow inter-marriage, must be familiar to everyone, who has been engaged in medical practice for many years.

(a) **Lecture delivered at the West-End Hospital, November, 22, 1906**

Over-production, prolonged lactation and disparity of age in the parents.—The arguments in favour of these influences are probably based on the facts, previously mentioned, that in the majority of the cases reported the disorder had attacked the members of large families. In one of the two just quoted, there were thirteen children, including two sets of twins, and in the other, ten; brothers and sisters. It is conceivable that the early marriages, rapid rate of reproduction, and the social surroundings of the less prosperous, and cultured classes of the community, may be to a certain extent responsible for the degeneration of stock.

Race and environment.—(8) The largest number of cases have been reported from America, and the smallest from France. (9) Collins, of New York, has recorded eight in his clinic in five years. There is good reason to suppose, that the disorder is more prevalent among the labouring, and agricultural population, and in rural, rather than in urban districts.

Proximate causation.—The immediate cause of the disease is unknown, but there are two antecedent conditions, which stand out with considerable prominence and frequency,

1. The acute infective disorders,
2. Trauma.

Many parents date the commencement of their children's nervous instability from one of the acute specific fevers, and of these, diphtheria and smallpox have the credit of being (10) "peculiarly efficacious in evoking the early symptoms."

Trauma has been blamed for precipitating the disorder, and the evidence produced appears to be trustworthy.

Sex.—The sexes are nearly equally affected, males slightly preponderating, albeit Friedreich held the opposite opinion.

In Soca's series the proportion was 68 males to 47 females.

Gowers gives the proportion at 35 males to 30 females.

In the eight cases reported by Collins, there were five males and three females.

Age Incidence.—The age at onset varies between two and twenty-four years. (11) "Out of 143 cases tabulated by Crozer Griffith 30 per cent. developed the disease before the sixth year of age, about 60 per cent. before the tenth year, and only 3 per cent. between the twentieth and twenty-fifth years." In these cases direct inheritance was traced in thirty-three.

Distribution of cases.—The number of cases in a single generation is very variable. Gowers records sixty-five in nineteen families (12) "giving an average of rather more than three to each." Certain clinical characteristics are observed in some families, and absent in others. In some the males are attacked, and the females escape; in others the contrary obtains. There is some foundation for Soca's law, that the onset of the disease occurs about the same age in the case of each member of the family affected, and the symptoms follow on similar lines.

Symptomatology.—The cardinal features of Friedreich's ataxy are, progressive weakness, and inco-ordination of the limbs, most marked in the legs, hypotonia, staggering ataxic gait, absence of deep reflexes, speech impairment, nystagmus, tremor, scoliosis, pes cavus, involuntary muscular movements, the extensor type of plantar response and certain other subordinate manifestations which will now be discussed in detail. Motor symptoms predominate and constitute by far the most important group of symptoms.

Ataxia.—The inco-ordination which, as a rule, is first noticed in the lower limbs and trunk, is both of the ordinary and static types. It commences with clumsiness or uncertainty in walking, and there is considerable difficulty in maintaining the erect position. Closure of the eyelids frequently increases the unsteadiness, but the symptom of Romberg is an uncertain quantity. Later the arms are affected, or the disease may start with inco-ordination of the upper limbs, (13) as in the case recorded by Besold, quoted by Mackie Whyte. The ataxy is slowly but steadily progressive, all four limbs becoming sooner or later involved, until the power of directing voluntary movement is lost.

Paralysis.—(14) Some degree of muscular weakness is associated with the ataxy, but it is neither general nor considerable until the later stages are reached; the muscles are inactive, their strength reduced, but the tonus is not diminished to the same extent as it is in tabes. The condition is therefore one of paresis without any serious paralytic state being present, until quite late in the disorder. Atrophy is observed in some cases of long standing, chiefly in the muscles of the shoulder girdle, pelvis, arms and hands. Two cases exhibited at the meeting of the Neurological Society in Queen's Square, on July 14th, showed a well marked main-en-griffe.

Attitude.—The position of patients in the early stage of Friedreich's ataxy is quite characteristic—they stand on a wide base, with the feet far apart, and turned outwards, the head and trunk inclining forwards, slightly in advance of the legs.

Gait.—The gait is swaying, and unsteady, resembling that of a person under the influence of alcohol. It was described by Charcot as the démarche tabeto-cérébelleuse.

Reflexes.—As a rule the knee-jerks are annulled early in the disease, but they (15) may be normal, or in very rare instances exaggerated. Crozer Griffith in the analysis of his 143 cases, found that abolition of the knee jerks was very early and constant. The ankle jerks are usually diminished, the superficial cutaneous reflexes are indefinite, generally retained, but the plantar response is nearly always of the extensor type, on one or both sides. The sphincters are rarely affected, except it be in the late stages of the malady.

Speech defects.—Articulatory impairment is not commonly an early feature, it is most frequently observed two or three years after the disease is recognised, or even later in its course. Like the limbs, the speech is ataxic, irregular, mangled or jerky, but in some cases it is blurred, explosive, monotonous or hesitating.

Deformities, scoliosis, kypho-scoliosis, pes cavus and contractures often occur. The spinal curvature occupies the dorsal and lumbar regions, and is usually one of the later symptoms. (16) Two cases have, however, been reported, one by Brock, and the other by James, both quoted by Mackie Whyte, in which the spinal deformity gave the earliest clue to the nature of the disease. The foot deformity is bilateral, and also one of the more advanced symptoms. It has been admirably described by Dr. Ormerod in *Brain*, January, 1888, and as it has been quoted elsewhere, no apology is needed for its reproduction here. "The instep becomes prominent, and the metatarsals appear to be shortened at the metatarso-phalangeal joints, the toes become over-extended, and the first inter-phalangeal joints flexed. The foot looks humpy and shortened. Below, the plantar arch (at least as seen from the inner side) is abnormally high, and the balls of the toes are very prominent. The foot also tends to assume the position of equino-varus."

Involuntary muscular movements.—Head swaying, coarse rhythmic tremors, choreiform, and salutation movements are frequently noticed; they may be provoked by attempts to move the extremities, and twitchings are sometimes seen when the body is at rest, or when the child begins to talk. In the advanced stages of the disorder the head not infrequently nods, or rolls from side to side in an extraordinary manner.

Cranial nerves.—The special senses of taste, hearing, and smell are seldom, if ever, affected, paralysis of the ocular muscles has rarely been noted, but diplopia, strabismus, and some degree of ptosis have been reported in a few of the cases; nystagmus is a frequent, but not constant sign. Strümpell says it is rare and not characteristic. It can, however, be discovered in most of the cases on lateral or upward deviation, particularly after fixation on a given object. Pallor of the discs, and optic atrophy, are rarely but occasionally observed. (17) Snell reports three cases in one family presenting some degree of it. At the Neurological Society's meeting in July one patient was shown by Dr. James Taylor with double primary optic atrophy, and concentric contraction of the visual fields, who was unable to count fingers beyond one or two feet, and another by Dr. Ormerod whose discs were markedly atrophic. In a third, exhibited by me—a sister of Dr. Ormerod's patient—there was distinct pallor of the discs, without any apparent impairment of sight. The pupillary reflex as a rule is normal.

The sisters are here this afternoon and I hope to show them to you presently. They are typical examples of the disease in different stages.

Facies.—The aspect of the victims of Friedreich's syndrome may be described as expressionless, with a peculiar appearance of hebetude; the drooping features, and partially-closed mouth are very typical, and so are the facial contortions, which precede the effort of speech or follow emotional excitement.

Intelligence.—Some grade of mental retardation is frequently noticed in these cases, especially in the late stages of the disorder, and memory may be impaired.

Vaso-motor and trophic changes are not usually observed. Some of the authors have reported coldness, and even cyanosis of the affected extremities (18) but the skin, and joints, as a rule, preserve their normal appearance, and the muscles do not waste until the disorder is far advanced.

Sensory symptoms.—Subjectively and objectively, alterations in tactile sensibility do not commonly form part of the clinical picture, nor is the muscular sense disturbed; (19) cramps and rheumatoid pains are sometimes complained of, and very rarely lightning pains have been reported. (20) Charcot showed that true tabetic pains have been encountered. In a certain number of the cases, anæsthesia, analgesia, paræsthesia and delay in conduction have been noted.

Visceral crises are said not to occur. This is not strictly correct—a girl, æt. 16, who was in this Hospital last May, under the care of my colleague, Dr. Outterson Wood, had a severe gastric crisis lasting thirteen days. It is interesting to relate that her elder sister, afflicted with the same disorder, who was in Westminster Hospital, under the care of Dr. Donkin, ten years ago, had a precisely similar crisis which lasted exactly the same time.

Electrical reactions.—Sir William Gowers quotes two cases reported by Dejerine, a brother and sister with great atrophy of the muscles, and altered electrical reactions. In the two cases I have tested there was no polar change.

Cardiac (21) *Tachycardia and a basic murmur* have not infrequently been observed in Friedreich's ataxia.

Menstruation is said to be often delayed. In the case of the girl just mentioned, the menstrual function was performed very regularly, but the tachycardia continued all the time she was in the hospital, the pulse rate was seldom, if ever, below 112.

Course and duration.—In the majority of the cases the ataxy first noticed in the lower limbs, extends to the arms in the course of four or five years, and by that time the patient is either unable to walk without assistance, or confined to bed or a chair. The symptoms which first attract attention in the order of frequency are: 1, the disorders in the gait; 2, the loss of the patellar reflex; 3, speech defects; 4, nystagmus; 5, scoliosis and hyperextension of the hallux. Any of these abnormalities occurring in a member of a family affected with the disorder, should at once raise a suspicion of a probable addition to the list.

The course of the disease, although essentially progressive, is measured by years of disability. Twenty or thirty years' duration is not exceptional. (22) "Long remissions may occur, and sudden aggravations take place." Death usually results from some intercurrent disease, seldom directly from the disorder. (23) The longest case on record is forty-six years, and the shortest only two years.

In sixteen autopsies recorded by Dana the duration of the disease was as follows: Thirteen cases lasted over ten years; two cases lasted over eight years; one case lasted two years.

Morbid anatomy.—The *post-mortem* changes in Friedreich's ataxia are extensive, and well marked. To the naked eye the cord appears to be undersized throughout its entire length (particularly in the dorsal region) and may present only two-thirds of its usual thickness. The lesion is a combined system degeneration of the postero-lateral tract. Sclerosis, not of the ordinary connective tissue type, but gliosis, or neurogliar sclerosis (ectodermal) of these regions. In its distribution the morbid process invades the columns of Goll and Burdach, the crossed pyramidal, direct cerebellar, Lissauer's and Gower's tracts, and the cells of Clarke's vesicular column are frequently atrophied.

Degenerative changes have also been found in the posterior horns, and rarely (Friedreich and Rütimeyer) in the anterior cornual cells. In a very few of the cases, lesions of the medulla, and cerebellum have been reported. (24) The cranial nerves usually escape, but the hypoglossus, and the optic nerves have been found diseased." Very little is known about the condition of the posterior ganglion cells, but the peripheral nerves do not appear to be concerned in the degenerative process.

Closely allied to the syndrome of Friedreich is the other form of hereditary ataxy, called the cerebellar, or Marie's type, with which it has many features in common. It commences later in life, seldom before the twentieth year, with paresis and inco-ordination of the lower limbs, articulatory defects, pronounced choreic movements, exaggerated knee kicks, and frequent ankle clonus, but nystagmus and deformities are rare. In this type, optic atrophy, amblyopia, diplopia, colour blindness and the Argyll-Robertson pupil are often encountered, together with sensory disturbances of various kinds; spasticity of the limbs develops later. Atrophy of the cerebellum has been found in some of the few cases reported. It seems probable that the co-ordinating mechanism is attacked in the cerebellum in Marie's type, and in the spinal cord in Friedreich's. The points of distinction between the two types of hereditary ataxy are briefly expressed in the following table:—

Friedreich's Syndrome.

Early onset, at or before puberty.
Reflexes diminished or absent.
Optic atrophy rare.
Choreic movements frequent.
Deformities common.

Marie's Syndrome.

Late onset, at or after twentieth year.
Reflexes increased.
Optic atrophy common.
Choreic movements very marked.
Deformities exceptional.

Regarded from a clinical standpoint the difference is not very great and there is evidently a disposition in both these types to meet each other more than half way in irregular cases.

In both forms of family ataxy, by whatever names they may be called, the fundamental factor is their probable dependence on some embryological defect in the nervous organisation, leading to premature exhaustion, and decay in certain parts of the cerebrospinal axis, chiefly of the columns of Goll, pyramidal tract, and cerebellum, whether it be, as Gower suggests, that these structures are endowed with a lower degree of vitality than normal, and are incapable of discharging their functions beyond a limited period; or that the demands made on the nervous mechanism during the developmental epochs are too severe, it is impossible to say.

The interesting series of cases published by Sanger-Brown indicate that the hereditary ataxias follow the general rule of familial nervous diseases in two important points.

1. Transmission by the female line.

2. The tendency to preponderance in the male sex.

His genealogical diagram in the summer number of *Brain*, 1892, shows a remarkable inclination of the disorder to attack the children of successive generations at a progressively earlier age, and is well worth a careful study.

Diagnosis and differentiation.—In well marked cases with a family history of other victims the diagnosis is almost self-evident, but in the sporadic examples, they may have to be distinguished from: 1, Marie's type of hereditary ataxy; 2, ataxic paraplegia; 3, hereditary tabes; 4, chorea; 5, insular sclerosis; 6, cerebellar neoplasms.

1. The first has already been discussed in detail.

2. From ataxic paraplegia, the diagnosis may be difficult, if not impossible, some assistance may, however, be obtained, from the presence of exaggerated knee jerks, and ankle clonus, which are not usually observed in Friedreich's syndrome.

3. From the inherited, or juvenile form of tabes, the disorder is distinguished by the absence of syphilitic stigmata, skin diseases, Hutchinson's teeth, choroiditis, and loss of the iris-reflex; a history of parental syphilis may also be useful. The tabetic gait lacks the staggering quality of the family ataxias, and the sphincter of the bladder is frequently affected.

4. *Sydenham's chorea* is a disease of abrupt onset, marked by general motor restlessness and irregular distribution of the movements, chiefly affecting the upper limbs. The reflexes are normal, or slightly exaggerated. Rheumatic taints in the parents or child are common and cardiac complications are frequent.

Huntingdon's chorea is seldom or never encountered in childhood, and only rarely at puberty. Its onset is much later in life, commonly between the thirty and forty-fifth years. The mental state, forced attitudes, and progressive depression which either accompanies, or in some instances precedes, the malady are signs of diagnostic value to be remembered.

5. *Insular sclerosis*, which Charcot said in 1868 "he believed was unknown in England," assumes so many disguises, and presents such a variety of masks, more particularly in those irregular types known as the "formes frustes," that the confusion of the French authors before Friedreich's ataxy had attained to the dignity of a separate existence is not to be wondered at. Even now, with our advanced knowledge of this disorder, and with broader views of its cardinal features, it is the one most likely in the earlier stages to be mistaken for the disease under consideration. We must recall the spastic gait, exaggerated reflexes, scanning, staccato speech, volitional tremor, frequent early sphincter trouble, nystagmus, disturbances of sensibility, occasional optic atrophy and the fact that disseminated sclerosis is seldom seen in children, and is most commonly a disease of early adult life, to help us in arriving at a correct conclusion.

6. *Cerebellar neoplasms* are distinguished by their prominent head symptoms, occipital pain, perhaps accompanied by tenderness or bulging of the cranium in that region, vertigo, vomiting, optic neuritis, neck rigidity, forced attitudes, the true cerebellar staggering gait, the distribution of the paralysis, and the involvement of any of the cranial nerves.

Prognosis.—The outlook in both forms of hereditary ataxy is always serious. No case yet reported has ever been known to recover. Some of them, however, appear to remain in a more or less stationary condition for considerable periods. (25) One, a tradesman, mentioned by Gowers, attended to his business for many years. Beyond the disability, the disorder is not usually associated with any marked or acute suffering—the victims bear their affliction with surprising calmness and resignation from onset to its natural goal.

Therapeusis.—From what has been said, very little improvement can be expected from treatment. There is no known remedy which influences materially the progressive course of the disease. Ladame suggests (26) "the application of continuous currents, stabile and labile to the vertebral column by means of large electrodes, 10 to 14 milliampères, three times a week." Some good results were reported by Charcot at the Salpêtrière from suspension. Phosphorus, silver nitrate, arsenic, ergot and antipyrin have been tried with indifferent success. In some cases they appear to have retarded for a time the progress of the malady. Bodily exercise should be avoided, but massage may be employed. It is conceivable that ultimately some serum may be discovered to arrest the retrograde process in the nervous mechanism on which the disorder depends. In the meantime, our chief reliance must be placed on a more careful and intelligent observance of the principles of hygiene, and the strenuous advocacy of prophylactic measures to combat those predispositional influences which are believed to be potential factors in the development of degenerative changes in the neuronic system. To wit, the encouragement of habits of temperance, the prevention of inter-marriage among blood relations, and to oppose the nursing of children by mothers whose history as regards familial nervous disorders is not irreproachable.

OPERATING THEATRES.

ROYAL EAR HOSPITAL.

Radical Mastoid Operation.—Mr. Macleod Yearsley operated on a woman, æt. 27, who had been admitted for recurrent discharge after ossiculectomy. When first seen in 1905 she gave a history of right purulent discharge since childhood, and stated that an operation for adenoids had been done fourteen years earlier. The ear was full of very foul débris and pus and there was a large perforation The ear was carefully cleansed and treatment carried out for several weeks; at the end of that time, as syringing caused vertigo, it was decided to remove the ossicles and outer attic wall. This was accordingly done and the patient made an uneventful and uninterrupted recovery. About a year after she contracted a very severe cold, experienced pain in the ear with vertigo; this latter was of horizontal character, was accompanied by nystagmus, and objects apparently moved towards the affected ear. There was a recurrence of discharge, and after cleansing the ear it was found that the tympanic opening of the aditus was partially occluded by a fibrous cicatrix. As treatment did not reduce the amount of discharge, it was decided to perform the radical operation. The patient was therefore anæsthetised and the usual incision made, the antrum was quickly reached, and on removing the posterior meatal wall it was found that there was considerable caries about the external semi-circular canal; there was also some caries about the entrance to the aditus and the facial nerve was exposed. The operation was concluded in the usual way, and a superior posterior meatal flap was fashioned and the wound sutured, packing being performed via the meatus. Mr. Yearsley pointed out that this was an instance of failure of the operation of ossiculectomy, and the case was interesting because it illustrated one of the ways in which this operation might fail, namely, partial occlusion of the tympanic opening of the aditus by scar tissue, whereby the drainage of the antrum would be interfered with. Had it not been for this it was quite possible that the re-infection of the ear by the severe catarrh of the upper air passage would not have been attended by such a grave result. This did not, however, reduce the value of ossiculectomy as an operation. In his experience it was a most useful method to adopt where there was caries of the ossicles as it provided for the removal of an irritating agent and also established good drainage. He thought that it was successful in at least 10 per cent. of cases, and it had the advantage of in no way interfering with the mastoid operation should this latter be required later. In this particular case the re-infection of the ear had resulted in an acute inflammation ofthe mastoid antrum with retention of products owing to the cicatricial obstruction he had already alluded to; this was accompanied by caries about the external semi-circular canal, which had given rise to the serious symptoms which necessitated the major operation.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of State Medicine.

Meeting Held Friday, April 19th, 1907.

The President F. C. Martley in the Chair.

The State and Syphilis.

Dr. **Seymour Stritch** read a paper on the above subject, and discussed the matter from its financial, vital, hygienic and legislative aspects. He endeavoured to show that the time had now come for an active crusade to be formulated by the Government and people against syphilis. He adduced figures to prove that the cost to the nation of venereal diseases in the army, navy and Government departments amount annually to no less a sum than £3,000,000, and that making allowances for superannuations and for sick leave occasioned indirectly through these diseases, though not appearing in the returns as such, he personally considers the more accurate estimate of this loss would be £7,000,000. The loss to the nation from death and disablement should be considered, not only from the point of view of syphilis only, but also from all those scrofulous and tubercular diseases which may be traceable from its origin (cancer of the tongue, throat, leucoplasia, &c.) The hygiene of syphilis might be dealt with from the basis of a trihedron supporting the principle of morality, sociality and legislation. The first of these was, he believed, more within the province of the church than that of medicine, and, therefore, resigned it into their hands. Socially, the disease might be combated by improving the environment of young men in business and in the services. Domestically, an endeavour to make the home attractions more pleasant than the seductions of the city should be the anxious endeavour of parents. By fathers retaining the confidences of their sons they could observe the bent of their minds, and by tactful insinuations create by suggestions the necessary antidote. The *morale* of the nursery should not be neglected owing to morbid curiosity of young nurses. Circumcision he believed worthy of being adopted universally. Boys should be encouraged to acknowledge any slip to their fathers. Lectures should be given in schools and ambulance classes on the dangers of venereal disease. He considered the question of legislation, as including a review of the Contagious Diseases Acts, could only be studied, like certain plays, in one's own room. He believed the Acts fulfilled their purpose, but for the general good should not be applied piecemeal or patchy-like to secluded areas, but rather throughout the empire. He believed that "given free dispensaries for men in each quarter of a city, the notification of the disease and punishment of those to whom its spread was traced, together with the compulsory detention and segregation of prostitutes whilst in an infectious condition, and also by the General Medical Council including dermatology and syphilis as a subject requiring evidence of special study during the curriculum of students"—given these, he believed that syphilis would become of but sporadic importance.

Colonel Butt, R.A.M.C., said his experience of the disease had been limited to the army, but he had often thought that the medical profession did not look at the matter as it ought, and that they, in common with the general public, did not look facts in the face and recognise that, notwithstanding all sorts of moral and educational influences, things were much the same as they had been in the past. Legislation was required for a section of the community who would not submit themselves to self-control. The State would be guided in the matter largely by the opinion of the medical profession, and yet the whole subject bristled with controversy largely as the result of ignorance. He was convinced that no advance could be made towards stamping out the scourge until every member of the profession took a whole-hearted interest in it. His own experience of his last three years in India had led him to the conviction that the disease could be stamped out. During that period, in a garrison of one thousand men, he had not one case of syphilis, although there were many prostitutes living on the confines of the garrison, and none of these contracted syphilis, although the number of syphilitics in the garrison never fell below one hundred. He admitted that the accomplishment of this was made easy for him by the magistrates, officers commanding, and his brother medical officers working with the one desire of stamping out the disease. They induced the soldiers to believe that they could benefit them by submitting to treatment. There was no stigma attached to women who suffered from venereal diseases going into cantonment general hospitals, and the native women attendants were got to explain to the women the benefits of treatment. The result was, he thought, strong presumptive evidence in support of his contention, that so long as local manifestations of the disease had been removed and the treatment was continued the disease could not be communicated. It had occurred to him that in order to get to influence the prostitutes to submit to treatment use might be made of the Salvation Army. That society had done immense good in other directions, and if it were shown that the profession was anxious to combat the disease on humanitarian grounds he believed the society would assist them. He believed that by treating syphilis patients as sufferers rather than offenders they could be got to submit to treatment, and that thus they would go a long way towards controlling what he considered a preventable disease.

Dr. **Henry FitzGibbon** said the difficulty which had always existed in dealing with patients in the

Lock Hospital had been the absence of controlling power to get the patients to remain under treatment. The tendency with the patients was to think that they were cured as soon as the disease was out of sight. Power was required to keep prostitutes in hospital as long as there was active syphilis present, and to keep them under observation and treatment as extern patients afterwards. There was also a difficulty in connection with young men who had not the means to pay for treatment, and who had no encouragement to go to general hospitals.

MAJOR BROWN, R.A.M.C., said that although he had never been able to connect syphilis and tuberculosis, as suggested by Dr. Stritch, he had always found that when syphilis was contracted by a patient with tuberculosis he went from bad to worse, no matter what the treatment was, unless he was seen early. As regards prevention, keeping boys at home was an excellent method, if it could be done; but a better plan was to protect them when they went abroad by legislating for them, and legislation meant bringing back the Contagious Diseases Act. The majority of those who indulged in that particular vice were not open to moral persuasion. Syphilis, of course, could be contracted in many ways, and there should be some place where it could be cured. Women, however, who practised as prostitutes were not open to moral persuasion, and the only way was to compel them to remain in hospital or to report to a doctor until they could be certified as free from the disease. Their efforts to stamp out the disease in the army did not seem to have had much effect. In Dublin, in 1906, the constantly sick from syphilis were 2.93 per 1,000, while in 1866 it was 1.72.

Dr. **PUGIN MELDON** said that one of the first difficulties in curtailing syphilis was the difficulty of diagnosing it early. He thought, however, that that would be only temporary, and that the bacteriologist would aid them in telling the patients definitely whether they were suffering from syphilis or not. A further difficulty was that of keeping prostitutes in the hospital. They went in readily enough as long as they were sore, but they went out in a short time and became infectious. This was the case with the very large percentage of patients who were also heavy drinkers. Soliciting in the streets should, he considered, be made illegal, and the punishment should depend on whether they were suffering from venereal disease or not. If suffering from disease, they should be confined in a lock ward or hospital, or in special prison wards, until cured, or allowed out on a ticket-of-leave principle. He considered also that any man who held connection with another individual while suffering from syphilis ought to be severely punished. The great difficulty in the way of legislative measures was the opinion of the public that the more syphilis was stamped out the more prostitution there would be. Their business, however, as medical men, was to check disease in every form. The presentation of the financial side of the question, as mentioned by Dr. Stritch, might smooth over the obstacle of public opinion. Seven million pounds lost to the nation meant twopence or threepence off the income tax. That was a fact which the general public would appreciate.

Dr. **KIRKPATRICK** said the question of State interference was as old as history. So far back as 1162 Parliament interfered for the regulation of brothels. If the public knew more of the history of the disease and the efforts which had been made to stamp it out the work of the medical profession at present would be much lessened. There seemed to be a general idea among the public that there was no regulation for State interference with venereal disease in Dublin. That was a mistake. Under the Act of Parliament, 5 Vict., c. 24, the police dealt very severely with prostitutes and soliciting, and in the Act, 48 and 49 Vict., there were very stringent regulations for the suppression of brothels. He had received from the Commissioner of Police a table showing the number of women proceeded against during the last five years, 601 being dealt with in 1906. During the same period twenty brothels had been suppressed in each year. This afforded them a starting-ground for an active crusade against the disease. It was not always, as was urged, a merited disease, and he had only recently seen the case of a woman who had been infected by her husband as the result of his contracting the disease during her pregnancy, and she had infected her child. The morbidity and mortality of the disease justified them in urging the State to interfere in the matter just as it was interfering in diseases that cost the State insignificant number of lives compared with syphilis. The sentiment of the country was against the official registration of prostitutes, and he would rather follow the suggestion that the laws at present in force should be used against solicitation, and a man who could be proved to have infected a woman with syphilis should be liable to similar punishment.

COLONEL BURTCHAELL said he had been in several American cities where prostitution was rampant, although the police arrangements absolutely prevented soliciting. If the prostitutes did not find the men, the men would find the prostitutes. The State legislated for zymotic diseases, but they were diseases of innocent people. Syphilis, however, was due to a voluntary act. If legislation was enacted it should be equally severe on the man and the woman, and he thought there should be some restriction on the marriage of syphilitics.

Dr. **WINTER** said that the debate showed that the profession were not of one mind. Their policy should go along three main lines—(1) They should educate the people, and to do so they must first educate themselves; then (2) they could proceed to agitate for State interference; having agitated sufficiently they could then (3) proceed to try to get the State to act. In the prevention of the disease there was the difficulty that young men could not get away from their employment continuously to attend hospital, and it occurred to him that a possible aid would be for some of the hospitals to start an evening dispensary for men. He believed they would remain under treatment if allowed. He did not think the police could be very active against soliciting.

Dr. **STRITCH** replied.

HARVEIAN SOCIETY OF LONDON.

MEETING HELD THURSDAY, APRIL 18TH, 1907.

The President, Dr. **SIDNEY PHILLIPS**, in the Chair.

MR. **F. JAFFREY**, F.R.C.S., read a joint paper by himself and Dr. A. **LATHAM**, entitled,

A CASE OF ULCERATIVE COLITIS; CÆCOSTOMY; COMPLETE RECOVERY,

which will be found fully reported on page 502 of the present issue.

In the discussion that followed,

Dr. **ALEXANDER MORRISON** spoke of the value of turpentine or terebene in these cases of ulcerative colitis, laying stress upon their styptic and antiseptic action.

Mr. **T. CRISP ENGLISH** referred to the relative merits of cæcostomy and appendicostomy.

The **PRESIDENT** said that only a few cases of ulcerative colitis require operation, among other indications being obstruction from atony and hæmorrhage. He referred to the value of adrenalin injection for hæmorrhage, and recommended mercury as being one of the best drugs for this disease. He pointed out the fact that hiccough is a frequent symptom, that embolism may occur, and that leucocytosis is present.

Dr. **ARTHUR LATHAM** said that in the great bulk of acute cases of ulcerative colitis, medicinal treatment does not control the disease, and he suggested that in the really acute cases surgical measures should be advised earlier than is the usual practice. Cæcostomy acts chiefly by resting the colon, and the washing out is probably of comparatively little use.

Mr. **JAFFREY** replied.

Dr. **Leonard Guthrie** read a paper on

FUNCTIONAL NERVOUS DISORDERS IN CHILDHOOD.

He suggested that all depended upon individual instability of the nervous system, and not upon the normal physiological instability common to all young subjects. Such instability was manifested in (1) *Derangement of co-ordination*, shown in nystagmus, head-rolling, and nodding, some cases of strabismus, congenital stridor, dysphagia, enuroesis, and stammering. (2) *Defective control* by higher over lower centres was instanced in chorea, the tics, some cases of recurrent pyrexia, and cyclic vomiting. (3) *Explosiveness* of higher centres accounted for epilepsy and eclampsia. (4) *Explosiveness* with readily induced exhaustion of psychical, sensory, and motor realms characterised hysteria. (5) *Irritability* and exhaustibility of all parts of the nervous system explained neurasthenia. (6) *Derangement* of the lymphatic and vaso-motor system was the cause of many functional ailments such as pseudo-angina palpitation, tachycardia, Graves' disease, dead fingers, atonic dyspepsia, entero-spasm, entero-ptosis, mucous diarrhœa, constipation, cyclic albuminuria. The sympathetic system was at the mercy of the mind, and most functional nervous disorders were the outcome of the neurotic or emotional temperament. The neurotic child was the father of the neurasthenic adult. The various types and characteristics of neurotic children were described. The importance of recognising such early signs as unusual timidity, tendency to brood, fret, and worry; hypersensitiveness of special senses, and of sensory organs in general, was emphasised. The influence of neuropathic inheritance and the effects of environment were considered in relation to neurasthenia. It was held that the neurotic temperament itself is in no sense morbid, though likely to become so under injudicious management. Educational over-pressure was attributed chiefly to fact-cramming, strain of defective memory, enforced concentration on uncongenial tasks, fear of failure and disappointment at want of success. Precocious children were no more liable than dullards to die young.

LIVERPOOL MEDICAL INSTITUTION.

Meeting held Thursday, April 18th, 1907.

Mr. Frank T. Paul, F.R.C.S., President, in the Chair.

CHRONIC SUPPURATIVE OTITIS MEDIA.

Mr. **E. M. Stockdale** read a note on the above with special reference to surgical treatment, based upon a series of cases which included sixty radical mastoid operations. He drew attention to the importance of skin grafting in certain cases, and mentioned the case of a bleeder in which frog skin had been used with excellent result. A case was related in which a baby, æt. 8 months, had suffered from a discharge from the left ear for seven months. Exploration revealed the fact that almost the whole of the mastoid and petrous portions of the temporal bone were necrosed. Removal of the diseased bone brought into view an extensive surface of dura mater covered by unhealthy granulations, both in the middle and posterior fossæ. A considerable portion of the lateral sinus was exposed and the internal carotid artery could be seen as it ascended to enter the skull. His experience showed that the hearing was often improved by the radical operation. The dangers of the disease and of the operation respectively were reviewed. His cases demonstrated that the danger of allowing the disease to run its course was much greater in every respect than the risk of even the radical operation.

Mr. **C. G. Lee** said he had watched the development of aural surgery from the time when a free incision into a post-aural abscess was thought to be all that was requisite; through the period when the mastoid was opened with a gimlet, the lateral sinus occasionally being opened accidentally up to the present when systematic and thorough surgical procedures happily held sway. Mr. Lee considered that the radical mastoid operation must rank as one of the most difficult in surgery.

Dr. **W. Milligan** remarked that the great difficulty was to determine the point at which local treatment should be given up and operative treatment instituted. For localised disease in the epitympanum and in the antrum removal of ossicles and the outer attic wall or Stacke's operation was as a rule sufficient. The great difficulty in practice was to determine the extent of the disease in the accessory cavities of the ear. An exploratory operation followed if need be by a complete radical operation was frequently indicated in chronic cases. He found, as Mr. Stockdale had said, that after many radical operations the hearing power was distinctly better than prior to operation.

EXTRAVERSION OF INTESTINAL MUCOUS MEMBRANE.

Mr. **G. P. Newbolt** showed this case after operation, having described and shown the case in its original condition before the Society on October 23rd of last year. The abdominal wall was now completely restored with the exception of a small sinus from which a little mucus sometimes escaped.

Mr. **R. W. Murray** advised leaving the sinus open.

COMPOUND FRACTURE OF THE HUMERUS.

Mr. **Rushton Parker** read a note on the above subject and showed a patient whose upper arm had been severely lacerated and the humerus broken transversely. Mr. Parker explained by means of lantern slides the way in which the ends of the bone had been kept in position by means of a sheet-iron twisted back-splint and two smaller lateral ones without having recourse to wiring. An excellent result had been secured. Radiographs were shown exhibiting the stages of callus formation.

THREE CASES OF EMPYEMA OF AN UNUSUAL NATURE.

Dr. **W. B. Warrington** read notes of, and commented on, the following cases:—(1) Empyema latent for over a year in a boy, æt. 17 years. There were very few symptoms, and spontaneous cure followed rupture of the empyema through the lung. (2) Empyema limited to the upper part of the thorax following pneumonia occurring in a patient who had six years previously had an empyema, which had been opened in the usual infra-scapular site. (3) Empyema in a boy, æt. 8 years. The physical signs were unusual, extended hyper-resonance, with amphoric breathing, coin sound and metallic tinkling, depression and rotation of the liver. An area of movable dulness in the lateral and basal regions of the right thorax. Dr. Warrington considered the symptoms were such as could be caused by air and fluid in the pleural cavity, though evidence as to the cause of a pneumothorax was wanting.

THREE CASES ILLUSTRATING SOME POINTS IN THE DIAGNOSIS OF ABNORMAL CONDITIONS WITHIN THE CHEST WALL.

Dr. **John Hay** read notes of these cases. (1) Actinomycosis of the lung simulating pulmonary tuberculosis, embolic pyemia, death. A girl, æt. 16, suffered from great dyspnœa, cough and anæmia and had been losing weight for six months. Pulse 160 per minute; signs of consolidation at the apex of the right lung. Three weeks later numerous abscesses had formed. Actinomycosis of the lung was diagnosed with a secondary actinomycotic pyemia. This diagnosis was proved to be correct by subsequent examination of the pus. (2) Centrally placed empyema not discovered by frequent exploratory aspirations. A woman, æt. 35, was admitted into the Stanley Hospital five weeks after a difficult confinement suffering from pain in the chest, pyrexia and cough. Ten days before admission she had a rigor and pain in her left side. Exploration of the chest gave a negative result. Later, the spleen was enlarged, the temperature remained elevated, and there was leucocytosis. Widal reaction negative. Exploration on two more occasions failed to locate pus, but finally it was found below the costal margin and the abscess was drained. The patient died the next day. The autopsy revealed an empyema in front of the root of the right ung adjacent to the pericardium. The pus had travelled down through the diaphragm and formed a sub-phrenic abscess. The recent delivery, the rigors, continued temperature, the normal position of the apex beat, the enlarged spleen, severe anæmia and the failure to strike pus all added to the difficulties. (3) A man, æt. 36, with marked dyspnœa, recurring hæmoptysis, cardio-pulmonary murmur audible at the mouth, but with slight physical signs, had contracted syphilis when aged 27. He first began to suffer from lung symptoms five years ago. The X-rays showed some fibrosis, especially at the root of the right lung, the apices were clear, the right side of the diaphragm limited in its movements. There was no history of night-sweats nor any abnormal temperature and there was no expectoration. Under treatment by mercury and potassium iodide the dyspnœa had greatly diminished, the cough had almost disappeared, the man's weight had increased, but the cardio-pulmonary murmur remained unaltered.

Dr. T. R. **Glynn** referred to a case of actinomycosis apparently commencing in the lung which he had seen with Dr. Thacker King. The victim of the disease was an elderly gentleman. The early symptoms were harrassing cough with the expectoration of blood and sanguineous mucus, later the development of a tumour on a leg in which the ray fungus was found. The mode of infection was not discovered.

Dr. T. R. **Bradshaw**, in discussing Dr. Warrington's cases, drew attention to the difficulty of distinguishing between empyema at the apex and a pulmonary abscess, pointing in the same situation. He narrated the case of a man who had pneumonia of the right apex. After a week fœtor was noticed in the breath for one day. A few days later a prominence was noticed below the right clavicle found on puncturing to contain fœtid pus. Operation showed that the abscess was in the lung and that it contained a large slough, which was removed. Recovery was satisfactory.

Dr. P. **Marsh** had seen a large number of cases of empyema at the infirmary for children, but never one with the physical signs as depicted in Dr. Warrington's case of pyo-pneumothorax. He had only seen two cases of pyo-pneumothorax, one of which was a tubercular case and the other followed the bursting of the empyema into a bronchus. He was astonished that so large a collection of fluid should cause so small an area of dulness as was shown in Dr. Warrington's diagram, and he doubted whether the pleural activity of a child of eight years would have a capacity to hold much air in addition to 40 ozs. of pus and compressed lung. He would like to ask two questions: (1) Whether there had been any escape of air when the pleural cavity was opened by the surgeon, and (2) whether an exploratory puncture had been made before the signs of pneumothorax had appeared as this operation had been known to cause pneumothorax. (Both these questions were answered in the negative).

Sir Chas. Barr, Dr. R. J. M. Buchanan, Dr. Grace-Calvert, Mr. R. M. Murray, Mr. T. Littler Jones, and the President also took part in the discussion on Dr. Warrington's and Dr. Hay's cases.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, May 5th, 1907

The Cries of Infants.

Two great varieties distinguish the cries of infants—the physiological cry and the pathological cry.

Children are frequently brought to the consulting-room because they cry unceasingly, and that is the only symptom complained of. The point is to be able to classify the cry under one or the other of the categories above-mentioned.

The most frequent cry is that produced by hunger, but more from a defect in the quality of the food than from the quantity; consequently, the consultant should examine closely the nourishing quality of the food given to the infant. Examine the breast of the nurse, or, if bottle fed, the quality of the milk; weigh the child before and after feeding to see if the quantity given is sufficient; every decrease in weight, unaccompanied with fever or diarrhœa, is due to a fault in nutrition.

Once the cries of hunger are eliminated, says Dr. Carriere, the cause must be pathological; the child cries from pain, and should be undressed, when frequently the cause is found to be a pin or a flea.

Generally the parents attribute the uneasiness of the infant to dentition. The eruption of the teeth might be incriminated if the little patient bites his fingers; the nipples of the feeding bottle or of the breast, if the gums are swollen and tender to touch. In such cases the gums should be rubbed by some sedative preparation.

Erythema of the thighs always provoke cries from the infant, and only cease when it is undressed and the parts powdered with talc or anointed with vaseline.

Another frequent cause of incessant cries is abscess developed in the cellular tissue, and especially in the folds of the umbilicus.

In osseous affections the cries are of extreme intensity and exasperated by the slightest movement. Consequently the different segments of the limbs should be examined one by one. It is thus that may be recognised osteo-myelitis, fractures, luxation, sprain, sub-periosteal sanguineous tumour of Barlow's disease, acute rheumatism (not rare in infants), or synovitis.

The glands should also be passed in review for possible adenitis.

If the examination has still given negative results, and that the mother says that the child cries especially after taking the breast or while it is sucking, attention should be drawn to the mouth and the throat, where aphthous stomatitis or tonsillitis may be discovered.

The public generally, and frequently with good reason, attribute the cries of infants to colic, which may be due to dyspepsia, dilatation of the stomach, enteritis, worms, &c.

There remains two other frequent causes of infant cries—otitis and meningitis.

In disease of the ear, they are inceasing and accompanied with high temperature. The suffering is increased when the ear or the mastoid process is touched. By the aid of the otoscope the cause of the pain is discovered, which is generally a boil or an abscess behind the tympanum. If a few drops of a solution of cocaine and oil (1—100) are poured into the middle ear, the boil or the drum can be incised, when all pain ceases.

The cries of meningitis are acute, short, monotonous, penetrating, and intermittent; they are accompanied by grimaces and pain which nothing relieves.

Treatment of External Tuberculosis.

The treatment by salt water of external tuberculosis is to-day of common practice. Dr. Regnier read a paper on it before the meeting of the Surgical Society a few weeks ago. The treatment is simple: Application of absorbent wool moistened with salt water, made with an ounce of the salts of chloro-sodic waters to a quart of boiled water.

A man suffered from suppuration of the shoulder for four months; through two fistulæ about five ounces of pus flowed out daily. He was greatly emaciated. The cause was tuberculous disease of the head of humerus. In spite of resection of the diseased bone and the filling of the cavity with iodoform gauze, the suppuration continued and amputation was thought necessary. However, M. Regnier, as a last resource, decided on irrigating the wounds with salt water and covering them with absorbent wool moistened with the same liquid. Gradually the suppuration ceased, the fistulæ closed, and the man recovered with a useful arm.

Another patient was also tuberculous. He coughed and presented several suppurating fistulæ, two on the sternum, one on the shoulder, one on the upper extremity of the humerus, and two on the elbow (resected a year before).

Over all these fistulæ, M. Pegnier applied the compresses of salt water during nine months. The fistulæ closed by degrees and to-day the patient is cured of all the external signs of tuberculosis, while the condition of the lungs has considerably improved.

GERMANY.

Berlin, May 5th, 1907.

A RUSSO-GERMAN Medical Society has recently been founded in Berlin, the object of which is the drawing together in fraternal intercourse the physicians of the two nations by means of personal intercourse and meetings of the Society in various places. The first presidents of the new Society are Prof. von Leyden, Berlin, Prof. Bechtereff, St. Petersburg, and Prof. Hildebrand, Berlin. The secretary is Dr. Lipleawsky, treasurer Dr. Weissbein, and librarian Dr. Kossmann. It is intended further to form a library, a polyclinic for poor Russians, and a Russian Hospital in the city, to be the headquarters of the Society.

The late Oberlandesgerichtsrat, Dr. Rothschild, the founder and president of the Köln Cremation Society, has left the whole of his fortune, amounting to a million marks, to the city of Köln. The condition on which it is left is that the city shall at once build a crematorium at a cost of not less than 100,000 marks. At a meeting of the city council on the 21st ult. the bequest, with its conditions, was unanimously accepted.

The thirtieth meeting of the German Society was held from April 3rd to the 6th. The president, Hr. Reichel alluded to the great loss the Society, the surgery of Germany, and of the whole world has sustained in the death of Ernest v. Bergmann. He took the opportunity of correcting certain incorrect reports that had been permitted to spread regarding the cause of his death. The deceased had suffered from dysentery during the Russo-Turkish war, but had apparently completely recovered from it. During the past few years several attacks of obstruction of the bowels had come on, the cause of which could not be made clear. They were, however, always overcome. A short time ago Prof. v. Bergmann had visited Wiesbaden on account of sciatica, the attack subsiding in a short time. Then suddenly a very violent attack of illness came on with vomiting, so much so that it became necessary to open the abdomen on the right side where there was violent pain. This operation was performed by Prof. Schlange, a former assistant of the deceased's. On account of the patient's great weakness only a cæcal fistula was formed. Then the most violent pain set in on the left side and Prof. Schlange (and not another surgeon as had been stated), at the express wish of his patient operated a second time on that side. It was evident that general peritonitis had already set in, and death rapidly took place. The autopsy showed a kink in the intestines caused by adhesions, a result of the old dysentery and fatty necrosis of the pancreas. We knew the speaker said how deleteriously the latter condition acted on already existing morbid conditions—hence medical art was powerless. The late professor was one of the founders of the Society, and was the thirteenth on the list; he also stood thirteenth on the list of those members that had died, the Society having lost thirteen of its members by death during the past year.

The president then turned to a more agreeable subject. On April 5th of the present year Lord Lister had completed his eightieth year. The management, in the name of the Society, sent a congratulatory address, drawn up by Hr. Körte and artistically engrossed to the benefactor of mankind, to whom many thousands of people every year were indebted for their lives and health.

The President then opened the professional part of the meeting, and observed that as the first meeting was usually attended by numerous ladies the first theme for discussion would be the heart.

Hr. Rehn Frankfort then introduced the subject of

THE SURGERY OF THE HEART AND PERICARDIUM.

He remarked that when he brought before the Society ten years ago the successful case of suture of the heart the majority of surgeons had been very sceptical on the matter. To his great joy they had now become confident. No case was known in which definite cessation of cardiac movement had taken place in consequence of the operation, even if death had taken place on the operating table from the excessive exhaustion of the patient. But we did occasionally observe when manipulation was prolonged or severe a temporary arrest of movement. Such was a warning to the surgeon to be exceedingly careful. Recent anatomical investigations had made distinct progress as regarded the centre for cardiac movements. Experiments made in the Aschoff Institute showed that when His's bundle was completely cut through the heart always ceased to contract, but not if even only a few fibres remained intact. This knowledge permitted us to operate on the heart quite energetically.

External inspection only rarely gave certainty as to wound of the heart. For the future an X-ray examination would often allow a conclusion to be reached. The situation of the external wound often indicated the existence of a wound. Symptoms were rarely absent in wounds of the heart; usually there was severe shock and free bleeding. The chief danger lay in bleeding to death and pressure from blood in the pericardium. When this was filled with blood the heart rotated on its axis in proportion to the degree of filling. Smaller effusions into the pericardium might prove fatal from causing over-fatigue to the heart. Characteristic symptoms following wounds of the heart were: pains in the left arm, precordial pain, pain in the abdomen, shortness of breath, cyanosis and torpor. One symptom that pointed to the injury was a systolic squirting sound.

If the weapon causing the wound was a knife, it should not be removed at once, as it dammed the route of the canal and acted as a tampon. If on opening the pericardium the blood squirted out the flow should be checked by pressure on the auricle. Contraction would begin again after pressure had been kept up a minute and a half, and after incomplete pressure for four minutes.

For the human heart these periods could be considerably lengthened. The vena cava was best compressed at the right auricle by a fork-like grasp with the second and third fingers.

The most unfortunate occurrence in suture of the heart was the cutting through of the sutures. All these patients died.

He advised that the pericardium should be sutured along with the heart itself, he would not pass the suture right through all the structures. Neither wire nor catgut should be used for sature material, but only fine silk. One hundred and twenty-four cases of suture of the heart had been published; of these 40 per cent. had recovered and 40 per cent. had died from septic infection.

AUSTRIA.

Vienna, May 5th 1907.

TEMPORAL ABSCESS FROM OTITIS.

ALT showed a case to the "Gesellschaft der Aerzte." In January the lad took influenza, followed by an acute inflammation of the right middle ear, with otorrhœa. A week later meningitis developed, and the lad was removed to hospital, where he appeared to suffer a good deal of pain in his stupor. The temperature ranged between 30.0° and 39.8° C., with a pulse of 84.

About this time the otorrhœa was very profuse, with perforation of the tympanum posteriorly and inferiorly, while the parotid and mastoid were very tender on pressure.

The left ear was quite normal; the right could detect whispers at one metre; the Weber test lateralised the right, while the Rinnie test was negative on the right, with prolonged osseous conduction—high tones being better heard than low.

Trepanning the right mastoid was then performed, relieving a large quantity of putrid pus extending vertically down the mastoid almost to the point, which was removed to give free vent. Eight days later the temperature was still at 39.6°, with stiffness of the neck, facial paralysis on the left side, fundus of left eyes normal, but the vessels of the right fundus were greatly enlarged and serpentine, while the temporal section of the papilla was adherent. These symptoms favoured an intra-cranial complication, as the left-sided facial paralysis would be expected from implication of the right temporal lobe of the brain.

This suggested another operation into the temporal lobe on the right side, where an abscess 1½ centimetres deep was found about the size of an apple. This was kept open for three weeks and carefully dressed with the insertion of a drainage tube. Everything prospered after this; the present shows a fine granulating wound nearly closed except the bony structure.

RHINOLITH.

Glus showed a patient from whom he had removed a calcareous mass that was situated below the lower turbinated bone over the eye-tooth.

After an attack of pleuro-pneumonia which the patient had last October, vomiting with a nasty fœtid smell commenced. The stomach and bowels were found to be healthy, which excited the presumption of the cause being buccal. The sputum was examined and purulent matter sometimes found. The patient was then taken to Chiari's Clinic, where the rhinoscope was used and the rhinolith discovered below the lower turbinated bone after a long examination, as it was surrounded with pus and a broken mass of tissue from the septum, as in all foreign bodies when long detained in the nasal cavity. After its removal the parts healed rapidly.

The most interesting points in this case are (*a*) the unusual anatomical position of the rhinolith, and (*b*) the anomaly of the circumstance. He must have carried this morbid body for years without trouble, till the influenza aggravated the surroundings and precipitated the morbid changes.

LUPUS VULGARIS EXULCERANS.

Freund presented a young woman whom he had cured by means of the rays. The lupus had destroyed a large part of the nose from the point backwards. Within two months after twelve sittings the nose was quite healed. Six applications had been added since as a prophylactic preparatory to a cosmetic operation to restore the outline of the nose.

PARALYSIS OF LOWER EXTREMITIES.

Moszkowicz next presented a boy, æt. 7, on whom he had operated for a contracted condition of the muscles of the leg resulting from paralysis in youth of both legs. Before the operation the boy was able to move like a four-footed animal. The knee-joints were stiffened from synarthrosis, while the tendons of the feet and hips were greatly shortened. The glutei maximi were useless as extensors, but the semitendinosus, semi-membranosus, and biceps were removed from the tuber ischii and attached to the os ileii. The knees were then straightened and the parts allowed to heal. With the assistance of two sticks the lad is now able to walk upright.

CHRONIC RHEUMATISM AND FIBROLYSIN.

Zuppenger presented a boy, æt. 12, who had typical articular rheumatism in 1899, which left him unable to move or turn himself, while the chin was so fixed on the sternum that he with difficulty took fluids. In this state he was received into hospital and after three weeks' treatment with fibrolysin injections the patient is able to move his head and freely open the mouth. He considers this a marvellous result after six years' fixation.

HUNGARY.

Budapest, May 5, 1907.

HYPEREMESIS GRAVIDARUM.

Dr. Odön Tuszkai, Gynæcologist in Marienbad and Budapest, concludes his investigations, carried on through several years, in the following summary:—

I.—Hyperemesis produced solely by gravidity, is one of the rarest complications of pregnancy.

II.—We have strictly to distinguish between vomitus gravidarum occurring during gestation and between hyperemesis gravidarum specifica. Also, we have carefully to discern by exclusion those diseases which cause vomiting in pregnant women, too; such as gastric troubles, meningitis, peritonitis, hydrops, &c.

III.—The diagnosis of hyperemesis gravidarum can be made with certainty under the following conditions: (*a*) If we were able certainly to exclude the diseases mentioned under II., viz., with the adoption of all the diagnostic and therapeutic methods and means; (*b*) If after these we find all the characteristic clinical symptoms, viz., great local tenderness of the peritoneum and of the uterus, which tenderness not only increases on bi-manual examination, but also gives rise to vomiting or violent retching and nausea; (*c*) If the frequent and severe vomitings occur also without taking food, and show within a short period the symptoms of inanition, and we find:

1. The quick decrease of the body weight, the daily quantity of urine, its chlorides and the red blood corpuscles of the blood.

2. The increase of the quantity of urine, its specific gravity, also the alkalinity of the blood and the pulse-rate.

3. The appearance of albumin and kidney elements in the urine and the presence of normoblasts and uninuclear megaloblasts in the blood.

(4) The sudden fall of the morning temperature, and in opposition to this, the febrile or subfebrile rise of the same.

IV.—The symptoms of hyperemesis gravidarum were explained from the irritation of the perimetrium, which most probably originates on account of its individual and occasional properties from a local atrophy, and thus is in causal nexus with gravidity.

V.—Prognosis is evidenced from the degree of inanition, in relation to the bodily condition of the individual. Evidence is gained by the above-described bio-chemical reactions.

VI.—On these grounds we shall be in the position to employ causal treatment, which in the forefront is conservative (local cold, heat, complete rest, large doses of opium), and only in cases of entire failure to interrupt pregnancy, when the life of the mother is endangered. This operation can be performed very easily and comfortably.

At the recent meeting of the Royal Society of Physicians of Budapest, Dr. Pandy exhibited a child that strikingly resembled a monkey. The head, attitude, manner of moving and walking of the child (a boy, æt. 10) reminded one of a monkey. His height was 103 cm., weight 16 kgr. The largest horizontal periphery of the skull amounted to 39 cm., forehead low, and bent backwards. The upper portion of the ears were narrowing; the chin was not prominent; the feet were loo long, the calves undeveloped. Thirty years ago, Dr. Vogt described similar small-headed children in order to prove that man originates from the monkeys. This statement has proved faulty, inasmuch as the resemblance affected only the head, and even here it was only superficial.

As for the treatment of small-headedness, which pathological condition involves also the smallness of the brain, some surgeons attempted to trephine the skull, in order to yield space to the brain for growth. But all these operations were futile. There is one medicine against small-headedness, that is, careful attention, thorough education, and systematic teaching of the child.

The commonest cause of small-headedness is excess in drinking. We all very well know that we are able to breed dwarf animals by giving them alcoholics. The habitual drunkenness of the father can produce small-headedness likewise epilepsy in the children. A drunkard, whom Dr. Pandy has known, had six hydrocephalic, and four microcephalic, idiotic children.

Dr. Tynatz Feldmann, prosector of the County Hospital in Békés-Gyula, read a paper on

Intestinal Obstruction as Complication of Gonorrhoic Epididymitis.

He could state from necropsy and from the results of bacteriological examinations, that gonorrhoic epididymitis} recte deferentitis was followed by the formation of a subperitoneal abscess on account of the perforation of the spermatic cord. The abscess produced a circumscript peritonitis, and this led to the adhesion of the bowels and finally to intestinal obstruction. The consecutive acute general peritonitis was caused by the obstruction.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

BELFAST.

The Health Commission.—For some days past the Health Commission has been hearing evidence on the Belfast water supply, much of the evidence being of great interest in view of the doubt which exists as to how far typhoid, epidemic and endemic, can be attributed to bad water, and how far to defective sanitation. The fact that the Water Commissioners are responsible for the one, and the Corporation for the other is, in this instance, an advantage, for each body has produced the best expert evidence available to help to elucidate the problem. Among the witnesses heard were Professor Lorrain Smith (late Professor of Bacteriology in Queen's College and now of Owen's College), Professor Symmers (the present professor at Queen's), Professor Letts (professor of chemistry at Queen's), Professor Frankland, and Drs. Gordon and Houston, of London, three experts retained by the Water Commissioners, Mr. Macassey, engineer and legal adviser to the same body. The water is derived chiefly from three sources: Stoneyford, near Lisburn; Woodburn, on the hills above Carrickfergus; and from the Mourne Mountains. The two first are agricultural land, with some population, and the last, which is intended eventually to be enlarged to supply the whole city if necessary, is wild mountain land. Professor Lorrain Smith said that he had investigated the typhoid question in Belfast in 1898 and in 1903. He did not consider the housing in Belfast worse than Manchester or Liverpool, which had about one-sixth as much typhoid. The disease did not occur where one would expect it, if due to bad sanitation, nor did he think milk could be blamed. But he looked on the presence of typhoid in the catchment area at Stoneyford as a very serious factor. He strongly advocated isolation. In Belfast there were only about 50 per cent. of the cases treated in hospital, while in Glasgow there were 91 per cent. Professor Symmers stated that he had entered into an experimental arrangement with the Corporation to make 100 analyses of water and milk per annum, for this year at any rate. He had examined eleven samples of water, but had not found any B. coli in any of them, in 100 c.c. In one sample he had found a bacillus which he regarded with extreme suspicion; it was very like the typhoid bacillus, but not identical with it, and he had never seen anything quite the same before. He believed there ought to be a bacteriologist to devote his whole time to the examination of the water, as the question of the typhoid infection was such an important one. The experts retained by the Water Commissioners described various investigations they had made, the result of which was that they admitted that the Woodburn and Stoneyford supplies were not quite satisfactory, in view of possible pollution of the catchment areas: but they did not consider that water stored as long as Belfast water is—200 days—ever produced typhoid. They also urged the fact that typhoid occurred all over the town, and not in the district supplied by any one of the sources, and also that it did not occur in the gaol, which is supplied with town water. Professor Letts said that on the ground of repeated chemical analyses he believed the water supply unsatisfactory. He strongly advocated the extension of the Mourne Mountains supply as an ideal one. Several other witnesses gave technical details about the working of the filtration beds, the distribution of the different supplies, &c. It is not easy to sum up the whole matter, but the general opinion would seem to be that while the Belfast water supply is open to grave suspicion, it can hardly be held entirely to blame for the constant presence of typhoid in the city.

LETTERS TO THE EDITOR.

MILK AND TUBERCULOSIS.

To the editor of The Medical Press and Circular.

Sir,—Dr. Granville Bantock's letters appear to me amusing in virtue of his standpoint, which seems somewhat that of Bantock *contra mundum* in all questions of modern bacteriological science. I am sorry if this displeases him. I admit it is not to the point. My point, like his as he avows it, is entirely practical. I would respectfully suggest to him that objective symptoms of tuberculosis rarely, if ever, appear until the lapse of a prolonged period after infection, and that this renders vain, in most cases, a search for the source of the poison. This is not the case in typhoid. Ten thousand instances could be adduced in which the contagium has been clearly followed to its course. A striking illustration was given in the High Court a year or so ago. An outbreak of typhoid was traced to the milk supplied by a leading London dairy company. The milk was derived from one of a number of farms whose produce the company dispensed. At the farm in question typhoid cases had occurred, and defective drains led the poison into the wells from which the water supply at the farm was drawn. The whole case was proved with scientific exactitude. I don't know what practical moral Dr. Granville Bantock wishes to draw from his argument, He seems to make light of the suggestion that we are to take any pains to guard our patients against poisoning from sources which the whole scientific world, except himself, seems to recognise. The case has been fully stated during the progress of bacteriological research; we all know it; you, Sir, certainly would not afford me space, if I were willing to tell the long story over again.

I am, Sir, yours truly,
A Family Doctor.

Bristol, May 3rd, 1907.

P.S.—It would be interesting to learn whether Dr. Bantock believes in a prophylaxis of tuberculosis, and if so, how he describes or formulates it.

PHARYNGO-KERATOSIS TREATED BY APPLICATIONS OF SALICYLIC ACID IN SULPHO-RICINATE OF SODA.

To the Editor of The Medical Press and Circular.

In the report of a case illustrating the above, which I brought before the Laryngological Society at its last meeting, a very important fact—and, indeed, the one which gave the main value to the case—was omitted. This was to the effect that the condition—best known as pharyngo-mycosis—was well marked on both tonsils, but that after the patient had made a daily application of a 10 per cent. solution of salicylic acid in sulpho-ricinate of soda to her right tonsil only, a slow but steady diminution in the size and in the consistency of the spots on it was observed after a few weeks. The other tonsil remained as before, until the same application was made to it also. This rigid experimental test showed incontrovertibly that the improvement was due to the application and not to any co-incidental spontaneous disappearance such as we know to take place from time to time in this disease. It is generally agreed that the condition is really one of no importance, and if a patient can be persuaded to disregard it, so much the better; for those, however, who are impatient of the condition, it is gratifying that there should be a method of treatment which has an unmistakable action on the keratotic condition and which can be placed in their own hands. The action is, of course, analagous to that of salicylic acid upon warts, corns, and similar conditions, and the sulphoricinate of soda seems to be the vehicle with which it can be incorporated as as to be as unirritating as possible. In view of the policy I have above described of dissuading patients from submitting to treatment for this condition, the opportunities for observing the effect of such treatment are obviously very few.

Thanking you for allowing me space for this communication,

I am, Sir, yours truly,
DUNDAS GRANT.

Cavendish Square, May 7th, 1907.

OBITUARY.

EDWARD MARKHAM SKERRITT, M.A., M.D.Lond. B.S., F.R.C.P.Lond.

WE regret to announce the death from pneumonia, after a short illness, of Dr. Edward Markham Skerritt, at his residence in Clifton, Bristol. Deceased was born in London in 1848, so that he was 58 years of age at the time of his death. His career has been one of brilliant success both at college and in after life. He relinquished the post of Dean of the Medical School only two years ago, having become first Dean of the Medical Faculty of University College, Bristol, in 1893. He was educated at Amersham Hall School, and University College Hospital, London, graduating B.A. at London University in 1868. He had a distinguished career as a student, taking many prizes and medals and the Atkinson-Morley scholarship at University College, London. He took the degrees of M.D. and B.S. (Honours) in 1873, and that of M.D. in 1874. He became a licentiate of the Royal College of Physicians, London, in 1873, member in 1876, and Fellow in 1885. He also became M.R.C.S., England, in 1873. He was gold medallist in medicine and obstetric medicine at the first M.B. examination, and obtained similar honours at the second M.B. examination.

He was elected physician of Bristol General Hospital in 1875, having at that time commenced practice there. He continued to serve the hospital for the rest of his life, being at the time of his death senior physician. He was a Fellow of University College, London, having previously filled the post of house-surgeon, assistant physician, and assistant in obstetrics there. He was a member of the Council of the Royal College of Physicians; vice-president (late treasurer) of the British Medical Association. For a period of some 26 years, Dr. Markham Skerritt, as Dean and joint professor of medicine, was prominently associated with medical education in Bristol. His loss will be deplored by a wide circle of friends and acquaintances, both social and professional.

The following comes from a personal friend and colleague:—

"I can supply a few details with regard to Skerritt. His latest appointment was that of Hon. Consulting Physician to the Cossham Memorial Hospital, Kingswood, a magnificent place to be opened in June next. Perhaps the chief characteristic of the man was the high standard he set in all matters of medical policy and medical ethics. In any matter of dispute between medical men, Skerritt was always sought for as referee, and his judgment implicitly relied upon. His medical consultation work was marked by rare common-sense. He never hesitated to say that a diagnosis could not be made immediately, and his diagnoses when made were nearly always correct. He had a firm belief in the curative powers of time and rest in bed, employing few drugs, and these of the simplest. His personality inspired great confidence both in patients and in medical men. He was a man of few words, and one whose shyness suggested, perhaps, sometimes a lack of sympathy, but his patients were firmly attached to him and the large attendance at his funeral (the largest I have seen in Bristol) were striking witnesses to the regard in which he was held. He was a strong total abstainer, a lover of horses and of fox-hunting. Latterly his wife's sudden blindness and his only child's premature death at the age of about 23, were heavy blows to him."

JOHN MACDOUGALL, M.D.GLAS.

THE death of Dr. John MacDougall, one of the oldest and best-known medical men in Greenock, occurred on Wednesday last with startling suddenness. At half-past five that morning, his wife noticed something wrong with him, but before anything could be done he expired. Although occupied the previous day, and in his usual apparent good health, with his duties, he expired suddenly in the bedroom in the presence of his wife in the early morning following. Deceased, who was over 70 years of age, graduated at Glasgow University in 1863, and had practised in Greenock ever since. He was police surgeon, a position he had held for about twenty-two years, and leaves a widow and a grown-up family.

SPECIAL ARTICLES.

THE NATIONAL SANATORIUM FOR CONSUMPTIVES, BENENDEN.

[BY OUR SPECIAL REPORTER.]

THE National Association for the Establishment and Maintenance of Sanatoria for Workers Suffering from Tuberculosis, justified its existence publicly on Tuesday April 30th, when Princess Christian formally inaugurated the opening of the portion of the Sanatorium at Benenden, in Kent, now available for patients. Visitors were conveyed by special train to Cranbrook, and thence for six miles by motors over the undulating hills of the Weald of Kent. Sir Clifton and Lady Robinson hospitably provided luncheon for the guests, among whom were Dr. Heron, Dr. Kelynack, Dr. T. D. Lister, Dr. A. Latham, and many well-known laymen. The new institution is a praiseworthy experiment to help the workers to help themselves. The Post Office employes and members of friendly societies are enthusiastically co-operating in the movement. The sanatorium is to be an example of the minimum of expenditure with the maximum of efficiency. It is estimated that the cost per bed will not exceed £100. The site is a good one, although the district is not easily accessible. An estate of 250 acres has been taken on which are two farms suitable as bases for the proposed Farm Colony, which is an essential part of the scheme. At present only a portion of the sanatorium is built. When completed, it will consist of a central block accommodating 68 patients, with scattered pavilions for ten patients in each, administrative block, dining hall, laundry, and electric light station. The buildings are being constructed as economically as possible. They are of steel framework, the intermediate space between the stanchions and girders being filled in with Frazzi cement rough-casted on the outside and plastered on the inside. The wards are floored with teak and the doors are of the same wood. The drainage is provided for by a septic tank system. Already there are a number of patients. Dr. Leonard Crossley is the resident physician. Mr. A. William West is the architect. Many have afforded the movement loyal support.

It is a rational attempt to secure effective co-operation and co-ordination of practical effort which will be watched in its future developments with sympathetic interest. Certainly the experiment should be carefully studied by all those desiring to render rational aid to the independent and self-respecting worker. The Prince of Wales is to preside at a dinner on the 14th inst., at which it is expected there will be ample practical evidence of the helpful interest taken by both medicals and laity in this praiseworthy national movement.

THE INFANTS' HOSPITAL.

[By our Special Reporter.]

The ancient and honourable City of Westminster on Thursday last, May 2nd, publicly recognised and accepted a unique addition to the many notable institutions which exist within its borders. H.R.H. The Duchess of Albany, the Patron of the new Infants' Hospital, formally laid the memorial stone.

The hospital, which has done much good work in a quiet way at Hampstead for several years, will shortly take up work in the new buildings, which already promises to form a most handsome institution overlooking Vincent Square, the playground of the Westminster schoolboys—an admirable position for such an institution. The hospital will provide accommodation for 50 infants. There is a well-designed Lecture Theatre with laboratory adjoining, and the institution may be expected to take a prominent part in that educational movement which seeks to arrest the deplorable wastage of infant life now so prevalent in London and all our large centres. Major-General Lord Cheylesmore, the Chairman of the Hospital, and Mr. J. S. Fletcher, M.P., its Vice-Chairman, detailed the work of the institution, and the Mayor of Westminster, who was accompanied by members of the City Council, also took part in the proceedings. Sir Lauder Brunton, one of the Consulting Physicians, and Drs. Ralph Vincent and T. N. Kelynack, the Physicians of the Hospital, with Mr. Mayo Robson, Dr. Sandwith, and Dr. F. J. Allan, were also present. The hospital is the munificent gift of Mr. Robert Mond, and forms a peculiarly fitting memorial of his wife. It is a greatly-needed addition to Metropolitan institutions caring for the young.

REVIEWS OF BOOKS.

THE RONTGEN RAYS IN MEDICAL WORK. (a)

Dr. Walsh's book, "The Röntgen Rays in Medical Work," hardly needs any commendation from us, for we venture to think that it is almost as well-known as the rays themselves; at any rate, to everyone who uses them therapeutically or skiagraphically this book has been guide, philosopher, and friend for the last ten years. The lawyer, too, finds it invaluable, and hardly a compensation case comes before the court without appeal and counter-appeal to its pages and illustrations. Its success is sufficiently demonstrated by the fact that frequent editions have been called for; indeed, the author more than hints in his preface that the present one has been due for some time, and would have been brought out earlier but for the demands that a complete survey of X-ray work necessarily made on his time. To this reason, too, is due the fact that Dr. Lewis Jones's lucid and interesting introductory series of chapters on Electrical Apparatus are found to contain one or two points which are disputable in the light of recent work, but of this first part generally it may be said—and we could give no higher praise—that it forms a complete and fitting introduction of the main thesis. For anyone unskilled in X-ray manipulations who wishes to render himself proficient, these first nine chapters will be found to supply all that he need know, set out with skill and clearness, and they will save any amount of heart-burnings if he keeps to them when at work, and eschews other and more loquacious guides, for the pictures are sufficiently numerous and well-set-out practically to allow a tyro to find his way by himself through all the intricacies of apparatus and machinery. Of Dr. Walsh's own chapters, which constitute three parts of the book, we can only say that they have been brought quite abreast of the newest facts and latest knowledge on the subject, without losing anything of their old freshness and charm. They are written with that clear knowledge and literary skill which enable the author in the course of each paragraph to present a pen-picture, precise and finished, of the condition he is describing; there is no redundancy, tedious detail, or vain repetition. Yet in the course of some three hundred pages he succeeds in covering the whole immense field now occupied by the X-rays in medicine, surgery, and therapeutics—certainly a highly-creditable achievement. The bulk of the work naturally is devoted to the various appearances of the bones and viscera in health and disease, but there are also sections on Dental Surgery, Nasal and Throat Surgery, Obstetrics and Gynæcology, Legal Medicine, Anatomy, Physiology, and Veterinary Surgery, all containing much valuable observation and instruction. One of the best parts of the section on Surgery is that dealing with the localisation of foreign bodies and injuries, in which the author is able from his wide experience to give many hints as to how to avoid the pitfalls which beset the expert witness who unwarily enters the box to give evidence based on X-ray photographs. Of the illustrations themselves, a hundred and seventy-two in number, it is hardly possible to speak without using terms that savour of exaggeration. They are by far the most beautiful, accurate, and artistic reproductions of X-ray photographs that we have seen, and we can only congratulate the author and publishers on having enriched surgical literature with such a unique and fascinating collection. It is difficult indeed, to know which takes our fancy the most. The photos of foreign bodies, especially Fig. 74, Three Bullets in the Head of a Cadaver; Fig. 77, Pin in Larynx; Fig. 80, Watch and Chain in Œsophagus, swallowed by "Ostrich Man"; Fig. 85, Stone in Kidney, are of first-rate excellence; but on the whole we prefer the photographs of the bones, especially those showing the absorption of lime-salts, and Fig. 155, Charcot Knee in a Woman, for to the practical worker they represent an even higher standard of technical skill. But there is nothing like a weak illustration among the collection, and some of the medical ones reach a high degree of excellence. We may then conclude this brief notice by saying that Walsh's "Röntgen Rays" well deserves its reputation as a standard authority on its own subject, and that in this new and improved edition we can predict for it even greater popularity and usefulness than it has attained in the past.

It is reported that owing to an outbreak of enteric fever Chelmsford Hospital has been closed to all but a few urgent cases. So far as can be ascertained at present the source of the mischief is an old sewer that passes beneath the building. The Hospital Committee have sent back to their homes all patients fit to be moved.

(a) "The Rontgen Rays in Medical Work." By David Walsh, M.D.Ed., Senior Physician Western Skin Hospital, London, and Hon. Physician Kensington General Hospital. Part I.—Electrical Apparatus. By H. Lewis Jones, M.D., F.R.C.P., Medical Officer in charge of the Electrical Department, St. Bartholomew's Hospital. Part II.—Medical and Surgical. By the Author. 4th Edition. 172 Illustrations. 15s. net. London: Bailliere, Tindall, and Cox, 8 Henrietta Street, Covent Garden, W.C.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT GYNÆCOLOGICAL AND OBSTETRICAL LITERATURE.

Tuberculosis of the Kidney.—Charles P. Noble (*Surg. Gynæ. and Obst.*, March, 1907). Ten years ago it was believed that tuberculosis of the kidney was frequently, if not usually, bilateral, and it was held that where it was not a part of a general tuberculosis it was usually a secondary condition due to tuberculosis of the bladder with ascending infection. As is well known, when not due to pyæmia or bacteriæmia, urethritis, pyelitis and pyelonephritis are commonly due to ascending infection from a primary cystitis, No evidence has ever come under my observation that tuberculosis of the kidney in women is ever due to ascending infection. On the contrary, in 50 per cent. of the cases the bladder was but little, if at all, infected, and in all the cases the ulceration of the bladder or cystitis has undergone either spontaneous recovery or has recovered after local treatment subsequent to the removal of the primary focus of the disease in the kidney by nephrectomy Cystitis existing as a complication of tuberculosis of the kidney is usually due to infection from the pus entering the bladder through the ureter. In a considerable percentage of the cases, however, there is a mixed infection, and the cystitis is due, not to tubercular infection, but to infection from some other organism.

Diagnosis.—The diagnosis of tuberculosis of the kidney is usually difficult except in late cases in which the kidney is much enlarged by pus contained within its capsule, or in which the presence of a perinephritic abscess, together with the history of the patient indicates the probable nature of the malady. In the majority of cases referred to the writer the diagnosis was cystitis. The first symptom, in most cases, is increased frequency of urination. Examination of the urine shows the presence of pus and the urine is usually acid, and these, combined with evidence of failing nutrition and discomfort in the region of one or the other kidney, are a combination of symptoms which should always raise one's suspicions. Blood in the urine is a frequent symptom, usually microscopical in amount, and pain, when present, is usually one of the evidences of extensive involvement of the kidney. The diagnosis is made positive by examination of urine for tubercle bacilli, by injection of urine into guinea pigs and by cystoscopy. F.

Pathological Changes Caused by the Gonococcus.—Auspach (*Amer. Jour. Obst.*, April, 1907). The gonococcus is a pus-producing organism, but it differs in many ways from the streptococcus or the staphylococcus. Although it usually affects mucous surfaces, it may burrow beneath them and cause a suppurative lesion (Wertheim). Besides the direct pus-producing action of the organism itself, whether it remains localised or is transported to distant joints or synovial sheaths there is another factor in the symptom complex. This factor is a toxine, called gonotoxin, which exists in the body of the diplococcus and is not set free till the organism dies. It is an endo-toxin—a bacterial protein. Wasserman found that the death of the gonococcus, after sterilising a culture, made the body of the organism exquisitely poisonous. The smallest quantity of this poison produced inflammatory symptoms at the point of applications, fever, swelling of the nearest lymph glands, and severe pain in the muscles and joints. There is no immunity to gonorrhœa in man, either naturally or by reason of a previous attack and in chronic gonorrhœa the individual is quite susceptible to a new super-imposed gonococcus infection. The gonococcus attacks an individual by means of the mucous membranes and usually by those of the genital organs. Upon the horny stratefied epithelial surface of the skin it has no effect; upon the squamos epithelium of the vulva and vagina it is less capable of harm than when it gains access to the transitisual epithelium of the urethra, or the columnar cells of Bartholin's glands or the cervix. What the organism lacks in its powers of invasion it makes up in persistency. According to many observers it never disappears spontaneously. It is quite common for the infectious process to leave the urethra and be hidden in the periurethral crypts. Here it slumbers, but is capable of being aroused into new activity by finding fresh grounds for invasion or by congestion of the tissues in its immediate vicinity. These peculiarities explain the clinical fact that an individual having no symptoms of gonorrhœa, but harbouring the gonococcus in his person, may produce an active infection in another, and this infection, after developing new activity in the second individual will cause a violent attack if returned to the first. F.

Management of the Adipose Layer in Suturing.—Robert T. Morris (*Jour. Obst. and Gynæ.*, March, 1907). All sutures which enter the adipose layer set free a certain amount of fat, and this free liquid fat leaves channels which must be closed by reparative processes, in a tissue which is badly equipped for carrying on repair. The principal of depending upon atmospheric pressure for keeping adipose tissue surfaces in contact is not universally employed by surgeons. The wet leather disc used by boys as a toy for lifting stones demonstrates the principle. The method adopted by the writer for many years is as follows:—(1) A continuous suture of very small catgut for the peritoneum; (2) a continuous suture of small or large catgut for the posterior and anterior sheaths of the abdominal muscles, allowing atmospheric pressure to close out "dead spaces" evenly in the muscle tissue; (3) a continuous catgut suture through the skin only, carefully avoiding the adipose layer. If the adipose faces of the wound are pressed snugly together before the last knot is tied, they will adhere so firmly and evenly that it will be difficult to separate them twenty-four hours later. F.

The Relations of Diseases of the Sigmoid Flexure to Diseases of the Female Genital Organs were discussed by Albrecht at the November meeting of the Munich Gynæcological Society (*Zentralbl. für Gyn.*, 1907 Nr. 17). The points which he brought forward were as follows: Firstly, owing to the over-filling of the flexure in cases of habitual constipation, fæcal tumours may arise which, under some circumstances, may be mistaken for tumours of the genital organs. Further, these fæcal accumulations are made responsible for a series of disturbances, for example, displacements of the uterus and ovaries, passive congestion of the pelvic plexuses, dysmenorrhœa and uterine hæmorrhage. The inflammatory processes which arise in the flexure itself are of importance as regards differential diagnosis and treatment. They may be (*a*) acute sigmoiditis, which may exactly resemble an acute pelvic peritonitis or an appendicitis; (*b*) chronic hyperplastic sigmoiditis with pains to the left of the hypogastrium resembling chronic inflammatory oöphoritis; (*c*) chronic pseudo-carcinomatous sigmoiditis with progressive stenosis of the lumen of the intestine, abscess formation, and perhaps perforation peritonitis. These conditions may just as easily be mistaken for pyosalpingitis as they may be for real carcinoma of the intestine. Perisigmoiditis may arise from extension of inflammation of the pelvic organs to the flexure, and, on the other hand, primary diseases of the flexure may extend to the ovaries, tubes, and uterus. Various adhesions, stenoses, kinking of the intestine, &c., may thus be produced. Finally, when considering the retroperitoneal lymphatics, the clinical picture of meso-sigmoiditis arises with a consequent parametritis or periproctitis.

G.

A Contribution to the Statistics of Placenta Prævia is recorded by Bürger and Graf (*Monatssch. für Geb. und Gyn.*, Bd. 25, Hft. 1) from the material of Schauta's Klinik in Vienna. They bring it forward on account of the recommendation by Dührssen and Bumm that vaginal Cæsarean section should be employed for the treatment of placenta prævia. They do not favour this method of treatment, because their own results with other methods are very good, and also because there is an unavoidable loss of blood during the performance of this operation among these cases, which may cause grave danger when much blood has already been lost. They also believe that the wounds produced in the richly vascular tissue of the lower uterine segment can be particularly easily infected. They, of course, allow that the prognosis for the child is better when this operation is performed, but they do not consider this of very great importance since the infants are frequently non-viable. They recommend the combined method of version which must not be followed by extraction. The results which they obtained are relatively good compared with other statistics, when one considers what a very dangerous complication of labour, from hæmorrhage and infection, the placenta prævia is. As regards the fœtal mortality the authors wish that it could be improved, but they do not consider that methods of improving it should be adopted which may cost the life of the mother.

G.

A Case of Supravaginal Amputation of a Fibroid Uterus between Four and Five Months Pregnant is recorded by Kayser (*Monatssch. für Geb. und Gyn.*, Bd. 25, Hft. 1). The patient, a nullipara, æt. 43, had been under treatment with ergot for a year on account of the myoma. During the last four months the abdomen had greatly increased in size, but in spite of this the patient had lost a good deal of weight. Examination revealed a tumour reaching to a hand's-breadth above the umbilicus. It felt extremely solid. The cervix was very high up. Some colostrum could be pressed out of the breasts. The legs were very much swollen. Severe dyspnœa and intestinal symptoms forced the author to operate, the diagnosis varying between a sarcomatous degeneration of a uterine myoma, or the combination of pregnancy with the myoma. The operation was easy, and the convalescence normal. The tumour removed weighed 13 lbs. When incised it was found to be pregnant between four and five months, the placenta situated on the upper portion of the posterior wall. A myoma larger than a man's head was situated with a broad base on the anterior wall of the pregnant uterus. It was only a little softened in the centre. Microscopic examination showed that the rapid increase in size of the myoma during the pregnancy was not due to an œdematous infiltration, but to genuine growth.

G.

The Treatment of Puerperal Mastitis.—The advantages of Bier's method of treatment are given by Thorbecke (*Med. Klinik*, 1906, Nr. 37, n. 38) as follows: In the first place, its power of removing the pain. The pain brings the patient to the doctor, and the result produced by the hyperæmia is wonderful. Generally, immediately after the first sitting there is a complete cessation of the pain, the patients feel much better, and trust in this unknown method grows. The patient's second question, "How long will the treatment take?" can also be answered. A few days when the inflammation is not severe; two to three weeks if it is severe. The temperature falls in about two days. If pus had already formed, its extension is prevented by the suction hyperæmia, its formation stopped, or the pus is altered into a serous fluid. Instead of the long incisions or complicated operations, to-day we only require punctures. The cosmetic effect is excellent, and the breast remains capable of performing its functions. The glandular tissue is not destroyed.

G.

MEDICAL NEWS IN BRIEF.

The Milk Supply and Sick Children.

A Conference on the subject of Milk Supply was held in London last week in the Board Room of the Hospital for Sick Children, Great Ormond Street, under the presidency of Mr. Arthur Lucas, chairman of the Hospital, at which representatives from the following hospitals were present:—The Hospital for Sick Children, Great Ormond Street; the East London Hospital for Children; the North Eastern Hospital for Children; the Victoria Hospital for Children; the Evelina Hospital for Sick Children; the Paddington Green Hospital for Children; the Royal Waterloo Hospital for Children and Women; the Alexandra Hospital for Children with Hip Disease; the London Hospital. The Conference, after discussion, passed the following resolutions, subject to the confirmation of the Committees of the various hospitals interested:—Recommendations adopted at a Conference of the United Children's hospitals of London. (1) The milk shall be pure, genuine, and with all its cream as yielded by the cow, and absolutely free from any and every kind of adulteration, including preservatives. It shall be of such quality as will produce at least 3.50 per cent. of butter fat. (2) It shall be supplied from a farm or farms whose name or names and locality are notified to the hospital. (3) It shall be permissible for an authorised representative of the hospital to inspect such farm or farms at any reasonable time. (4) The cows supplying the milk shall be in a good state of health, and a veterinary surgeon shall give a certificate to that effect once a quarter. (5) The milk shall be strained and refrigerated at the farm, and there canned and sealed. (6) The milk shall be delivered, sealed, at the hospital. (7) It shall not be "pasteurized," or treated otherwise than as mentioned in Clause V., without the written sanction of the hospital authorities. (8) It is advisable that the milk be tested bacteriologically and chemically once a week by the hospital. (9) That the name of the medical officer of health of the district in which a supplying farm is situated be furnished by the contractor, and that he be informed of the relations between the farm and the hospitals, and that he and the clerk of the urban or rural district council be supplied by the hospital, for their information, with a copy of these recommendations. (10) This Conference invites the committees of the various hospitals interested to adopt the resolutions passed at this meeting.

Royal Opening of Tottenham Hospital New Wards.

Yesterday (Tuesday) was quite a gala day in the North of London, as H.R.H. the Prince of Wales honoured the governors and medical staff of the Tottenham Hospital by being present at the opening of the new wards and theatre, and also by Her Royal Highness the Princess of Wales graciously consenting to receive purses towards defraying the debt on this very useful institution and to meet some of the current expenses for the new buildings. In the evening the medical staff of the North-East London Post-Graduate College held a conversazione, which was largely attended by members of the profession. The new wards and theatre were greatly admired. There was also a medical and surgical exhibition, at which music and refreshments were provided.

The United Services Medical Society.

A largely-attended meeting of officers of the medical services of the Navy, the Army, the Indian Army, and the Auxiliary Forces was held last week at the Royal United Service Institution, to consider the advisability of creating a United Services Medical Society. Inspector-General H. M. Ellis, director-general of the medical department of the Navy, presided, and explained that there were so many points where the interests of the different services met that it was desirable to form a society which would help towards co-operation. The present was a peculiarly fitting time, as the R.A.M.C. had now got a home in London, and it was from the Army Medical Department that the inception of the movement had come. He then explained the proposed constitution of the society, to be known as "The United Services Medical Society," ordinary meetings of which are to be held monthly in London. The scheme was unanimously adopted, and the Chairman elected its first President. The following were elected officers, representing the different services:—Fleet Surgeon Craig, Fleet Surgeon Dalton, for the Navy; Major Holt and Lieutenant-Colonel Cottell, for the Army; Lieutenant-Colonel Sir R. Havelock Charles, Lieutenant-Colonel Freyer, for the Indian Army; Lieutenant-Colonel Sir J. Clark, Lieutenant-Colonel Valentine Matthews, for the Auxiliary Forces. There will also be four *ex officio* members of the council—the directors-general, Navy and Army Medical Services, the president of the Medical Board at the Indian Office, and the commandant, Royal Army Medical College.

Action for Slander by a Medical Man.

During the past week, in the Nisi Prius Court, Dublin, Dr. David Turner, of Rathmines, near Dublin, claimed £1,000 damages from Mr. R. D. P. Darby, a retired Post Office official, for slander. Among other statements made by the defendant was one to the effect that if an inquest had been held upon his wife, Dr. Turner "would swing for it." There was also a suggestion that Dr. Turner had improperly obtained possession of a sum of money belonging to the defendant. Defendant denied that he ever spoke falsely or maliciously or published the words attributed to him, but admitted that he stated he was going to summon plaintiff for an account of the moneys entrusted to him and which he refused to pay. Defendant further in reference to some of the words complained of pleaded privilege, submitting that he was entitled to speak of what he considered the negligence of the plaintiff in attending on his wife. Dr. Wallace Beatty and Dr. J. H. Glenn gave evidence on behalf of the plaintiff to the effect that his treatment of Mrs. Darby was right and proper. The jury, after a short consultation, returned a verdict for the plaintiff, Dr. Turner, and assessed the damages at £100. The defendant further gave an undertaking that he would not hereafter directly or indirectly annoy Dr. Turner by publishing any defamatory matter.

Midland Medical Union.

At the Sixth Annual Meeting of the Midland Medical Union held at Chesterfield last week, Dr. J. G. Shea in the Chair, the Annual Report for the year 1906 was presented, and adopted, the accounts showing a balance in hand of £19 8s. 7d. Mr. A. Chawner, of Clay Cross was re-elected President for the year. The other officers elected were: Hon. treasurer, F. R. Mutch, M.D.; Hon. auditors, A. Fulton, M.B., and J. H. Cox, M.R.C.S.; General secretary, G. S. O'Rorke, M.A., LL.D. Council: Representing the Nottingham Branch, A. Fulton, M.B., J. Holmes Thompson, M.B., J. H. Cox, M.R.C.S.; representing the Mansfield Branch, T. Tate, M.D., J.P., E. H. Houfton, M.D. (hon. sec.). Representing the Belper branch, R. G. Allen, M.R.C.S., G. G. Macdonald, M.D., J.P., W. Brownlow Smith, M.D. (hon. sec.). Representing the Chesterfield branch, J. G. Shea, M.D., J.P., S. Worthington, M.D., F.R.C.S., G. Booth, M.D., J.P., W. Duncan, M.B. (hon. sec.). After the meeting the annual dinner of the Chesterfield branch was held at the Hotel Portland, Chesterfield.

Medical Sickness and Accident Society.

At the Monthly Meeting of the Executive Committee of this society, held last week, Dr. de Havilland-Hall in the Chair, there were present Dr. J. Brindley James, Mr. F. S. Edwards, Mr. H. P. Symonds (Oxford), Dr. Walter Smith, Dr. J. W. Hunt, Mr. J. F. Colyer, Dr. W. Knowsley Sibley, Dr. Frederick S. Palmer, Mr. Edward Bartlett, and Dr. J. B. Ball. The accounts presented showed that the number of claims now being received on account of influenza is rapidly lessening, and there is reason to hope that the epidemic which appreciably added to the sickness experience of the early part of the year has now nearly subsided. The annual general meeting of the Society will be held at the rooms of the Medical Society of London on the 23rd inst., and the Report then to be presented to the members shows that, in 1906, the business was very successful and produced a considerable increase in the large reserves of the Society.

Medical Defence Union.

We are asked to announce that the Annual General Meeting of this Association will be held at the Midland Hotel, Manchester, on Thursday, May 16th, to receive the Annual Report of the Council and the Statement of Accounts, together with the Auditor's Certificate, for the year 1906; to elect three members of Council, Dr. J. Roche Lynch, L.R.C.P., Dr. A. A. Mackeith, M.B., C.M., and Dr. F. J. Wethered, F.R.C.P., hon. treasurer, retiring by ballot under Rule 28, but offering themselves for re-election; to appoint an auditor and to fix his remuneration, and to vote for the payment of railway fares as expenses incurred by provincial members of the Council attending Council meetings.

A Liverpool Injunction.

In the High Court, on April 24th, Mr. Rutherford moved before Mr. Justice Neville, on behalf of the plaintiffs, a Liverpool firm, in the action Evans, Sons, Lescher, and Webb, Limited, *v.* Ashford, for an injunction to restrain the defendant, a chemist at Northampton, from selling as Evans's antiseptic throat pastilles, pastilles not of the plaintiffs' manufacture. Mr. Hewitt appeared for the defendant, and agreed to treat the motion as the trial of the action, and submit to a perpetual injunction and to pay the costs of the action. Mr. Rutherford accepted the terms offered, and his lordship made an order on the terms agreed.

The Chemists' Exhibition.

The Chemists' Exhibition is being held at the Royal Horticultural Hall, Westminster, this week, from Monday to Friday inclusive, and is open each day from 11 a.m. to 10 p.m. The opening ceremony was performed by Mr. Idris, M.P. A novel feature in connection with the exhibition is that all London chemists residing within the four-mile radius will have their cab fares paid to the hall, while those from the country will get a rebate from the cost of their railway tickets.

The Irish University Scheme.

The principal, professors, and lecturers of University College, Bristol, have presented a memorial to the Chief Secretary for Ireland in which they state that they regard with serious apprehension any solution of the Irish University question that would deprive Trinity College of its autonomy, or limit its freedom by associating with it in the University of Dublin colleges differing from it in type and animated by incompatible ideals.

PASS LISTS.

Royal College of Physicians of London.

At the ordinary quarterly *Comitia* of the Royal College of Physicians, held on April 25th, the President of the college, Sir R. Douglas Powell, occupying the chair, the following members of the college were elected Fellows:—J. Barry Ball, M.D.Lond.; Edwin Bramwell, M.D.Edinb., of Edinburgh; E. Mansfield Brockbank, M.D.Vict., of Manchester; Daniel Colquhoun, M.D.Lond., of Dunedin, New Zealand; Andrew Duncan, M.D.Lond.; W. James Fenton, M.D.Camb.; H. Stanley French, M.D.Oxf.; Robert Jones, M.D. Lond.; Thomas McCrae, M.D. Toronto, of Baltimore, U.S.A.; G. Edward Rennie, M.D.Lond., of Sydney, New South Wales; Arthur Shadwell, M.D.Oxf.; and A. Thomas Wilkinson, M.D.Lond., of Manchester.

The following licentiates of the college, having passed the required examinations, were admitted members of the college :—J. M. Bernstein, M.B.Lond., of Owens College, Manchester; W. Edgecombe, M.D.Lond., Univ. Coll., Liverpool, and London Hospital; D. C. O. Finigan, M.D.Berlin, Berlin, Kiel, and St. Bartholomew's; A. M. H. Gray, M.D.Lond., of Univ. Coll. Hosp.; T. Lewis, M.B.Lond., Univ. Coll. Hosp.; N. Neild, M.B.Vict., Owens Coll., Manchester; C. S. White, M.D.Lond., Univ. Coll. Hospital.

Royal Colleges of Physicians and Surgeons Edinburgh and Faculty of Physicians and Surgeons, of Glasgow.

AT the April sittings of the Conjoint Board the following candidates passed the respective examinations :—

First Examination, Five Years' Course.—Tom Entwisle Ferguson, Bolton; Colin Hunter, Glasgow; Allan Ross Henry, Cape Colony; Hugh Francis Williams, Llanfyllin; Ishwar Das, Punjab, India; Patrick Walsh, Co. Limerick; John Scott, Dalry, Aryshire; Charles Stuart Ogilvy, Blantyre; William Woodburn M'Cowat, Transvaal.

First Examination, Four Years' Course.—Thomas Mitchell Jamieson, Co. Tyrone.

Second Examination, Five Years' Course.—David Lindsay Hutton, Glasgow (with distinction); Ernest Averell, Newcastle-on-Tyne; Robert Stobbo Watt, Glasgow; Arthur Duncan Macarthur, Pollokshields; Robert Miller Danks, Coatbridge; Michael Vincent Walsh, Cork; Hugh M'Ilroy, Co. Antrim; Robert Anderson, Beith.

Third Examination.—Abraham David Woolf, Birmingham; Henry William Turner, Glasgow; John M. Calb, Ulverston, Tasmania; James Thomas Gwynne Jones, Brecon, Wales; Abdul Majid Shah, Patiala, India; Ernest Gibson, Cork; David Welsh, Lanarkshire; Ishwar Das, Punjab, India; Archibald Davidson, Melbourne; Maurice Edward Kayton, Bagdad; George Noel Braham, Bath.

Final Examination and Admitted Licentiates of the Co-operating Authorities.—Shridhar Chintaman Jog, Edinburgh; Joseph Hume Patterson, Glasgow; Oliver David Gunasekara, Colombo, Ceylon; Fred Garnet Allan, Whaley Bridge, Cheshire; Hugh Ferguson Watson, Gartnavel; Edward Robert Harriott, Jamaica; Arthur Annesley Stork Kats, Ceylon; Effie Jemima Cassels, Glasgow; Charlott, Eliza Pring, Bristol; Phiroza Behranji Malabarie Bombay; Emile Hamel Smith, Edinburgh; Frederic James Breakell, Glasgow; Malcolm Ross Slack, Canada; Hugh Graham Anderson, Newlands, Glasgow; Ada Geraldine Boylette-Dias, Bombay; Hiralal Keshavlal Nanavati, Glasgow; Lennox Donald Napier, Egremont, Cheshire; William Frederick Fismer Durr, Glasgow.

University of Durham.

THE following candidates have satisfied the Examiners during the April examinations :—

FIRST EXAMINATION FOR THE DEGREE OF BACHELOR IN MEDICINE.

1. *Elementary Anatomy and Biology, Chemistry and Physics.*—William G. Bendle (Honours, second class). *Pass List*: Francis P. Evers, William J. Hickey, Carl J. V. Swahnberg, Harold F. Stephens, Robert W. Smith, Alfred T. Thompson, Thomas R. West.

2. *Elementary Anatomy and Biology.*—John E. Alderson, Richard M. Barrow, Roger Errington, D. Farquharson, Sarah L. Green, Thomas A. Hindmarsh, Arthur S. Hopgood, Tom M. Hopgood, Frank H. Kennedy, Richard B. Lilly, John Lumb, Benjamin B. Noble, Thomas A. Peel, Arthur H. Wear.

3. *Chemistry and Physics.*—Everard C. Abraham, Louis E. S. Gellé, Harold L. James, Hubert V. Leigh, George C. M. M'Gonigle, Oswald S. Norton, Henri R. G. Vander Beken.

4. *Elementary Anatomy.*—William Smith, B.Sc.

SECOND EXAMINATION FOR THE DEGREE OF BACHELOR IN MEDICINE.

Anatomy, Physiology, and Materia Medica.—Jabez E. Dainty (Honours, first class). Charles Marks (Honours, second class). *Pass List*: Hubert C. W. Allott, Wilfred Barkes, John A. Caulcrick, Francis H. Fawkes, Herbert E. Fullerton, Cyril J. Henderson, Francis F. T. Hare, Satyen Mozumder, William Reynolds, William Sacco, Dorothea M. Tudor, William R. E. Unthank, Charles L. Wigan.

The following candidates have passed the Third Examination for the Degree of Bachelor in Medicine :—

Pathology, Medical Jurisprudence, Public Health, and Elementary Bacteriology.—Braithwaite, Eldred Curwen (honours, first class).

Pass List.—Leonard F. Browne; Charles E. L. Burman; John Everidge; Reginald Francis; Arthur C. Greene; Hedvig C. Kellgreen; Raghunath V., Khedkar, L.R.C.P. & S., E L.F.P.S., G.; Herbert R. McAleenan; Friederike Rahtkens; Eric F. Waddington.

THE following Degrees have been conferred :—

Doctor in Medicine.—Robert Simpson Hindmarch, M.B., B.S., Durh.; Andrew Banks Raffle, M.B., B.S. Durh.; Norcliffe Roberts, M.B., B.S., Durh.; Frederick Riddle Scott, M.B., B.S., Durh.; Alan Fyre Smith, M.B., B.S., Durh.

Doctor in Medicine for Practitioners of Fifteen Years' Standing.—Edwin A. Bennett, L.R.C.S.E., L.S.A.; Joseph Buck, L.R.C.P.& S.E., L.F.P.S.G.; John M. C. Cole, M.R.C.S., L.M., L.K.Q.C.P.I.; Charles T. T. Comber, M.R.C.S., L.R.C.P.; Alexander Cuffe, F.R.C.S.I., L.A.H.; Harry Legh de Legh, M.R.C.S., L.R.C.P.; William C. Ellis, L.R.C.P.& S.E., L.F.P.S.G. L.S.A.; Charles J. Horner, M.R.C.S., L.R.C.P. L.S.A., Timothy Leahy-Lynch, L.R.C.P.& S., L.F.P.S. G.; Thomas McMillan, L.R.C.P.& S., F.L.P.S.G.; Edward Posnett, M.R.C.S., L.R.C.P., L.S.A.; Colamaranaucppi B. Ramarao, B.A., L.M.&S., Madras; Howard Slater, M.R.C.S., L.R.C.P., L.S.A.; Peter C. Smith, L.R.C.P.& S., L.F.P.S.G.; David T. Wylie, L.R.C.S.I., L.M.

Bachelor in Medicine (M.B.).—Harold H. Blake, Gilbert I. Cumberlege, William M. Emmerson, L.S.A., S.Havelock, B.Sc., Thomas D. Miller, M.R.C.S., L.R.C.P., David Ranken, Howard B. Stephenson, L.R.C.P.&S.E., L.F.P.S.G., Norman Spedding, Richard W. Swayne, Herbert H. Whaite, L.R.C.P.&S.E., L.F.P.S.G.

Bachelor in Surgery (B.S.).—Harold Henry Blake, Gilbert I. Cumberlege, William M. Emmerson, L.S.A., Sydney Havelock, B.Sc., Thomas Miller, M.R.C.S., L.R.C.P., David Ranken, Howard B. Stephenson, L.R.C.P.&S.E., L.F.P.S.G., Norman Spedding, Richard Swayne, Herbert H. Whaite, L.R.C.P.&S.E., L.F.P.S.G.

And the following received the Diploma in Public Health: Ernest G. D. Benson, L.R.C.P.&S.E., L.F.P.S.G.

The Royal University of Ireland.

THE following candidates have passed the Third Examination in Medicine :—

Upper Pass.—John A. Black,* James A. Brown, *Thomas P. Carroll, *John J. Gilmore, *James McCormick, *James M. O'Connor, Thomas Taylor. Those marked with an asterisk may present themselves for the further examination for honours.

Pass.—Charles Alexander, Francis Bradley, Joseph D. G. Burke, Bartley Byrne, Samuel Campbell, Samuel R. Campbell, Edgar N. Condy, Nicholas Cunningham, Elliot P. Dewar, James E. English, Edward Forbes, William A. Frost, John W. Garry, David J. Jackson, Thomas Kennedy, Caroline V. Lawe, Mathew J. McGrath, Harris Newman, Peter H. O'Connell, Arthur P. O'Connor, B.A., John P. J. O'Connor, Patrick C. O'Donnell, James J. O'Kelly, B.A., Robert H. Robinson, William H. Sheffield, Standish J. Watson.

NOTICES TO CORRESPONDENTS, &c.

☞ **CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

BRADFORD M.B.—Yes, since there are several such associations of ladies and disinterested layman, who place themselves at the disposal of the M.O.H. for the purpose of keeping an eye on, and giving a helping hand to, the poor, but the only one we know working solely in connection with infant mortality was formed last month at Glasgow. The ladies form committees and visit all slum infants born, and instruct the mothers in methods of feeding, &c. A letter to the Town Clerk would give you the information probably.

ODONT.—The London Counties Medical Protection Society is, we believe, the only one of the defence organisations that admits dentists to its membership; the Medical Defence Union consists only of doctors. You had, therefore, better apply to the Secretary of the former.

FILLET.—(1) The Monmouthshire C.C. is one of the authorities which has instituted its own training centre for midwives. (2) The address of the superintendent is Sister Barrett, 30 Herbert Street, Newport. (3) Last year's report looked very satisfactory, but we cannot say more at the moment.

AN ABERNETHY STORY.

AMONG the many Abernethy stories that are known to medical men, we doubt if the following occupies a foremost position. It concerns the time when the great surgeon was seeking election at St. Bartholomew's, the duties of which candidature included the canvassing of all the governors. Abernethy's uncompromising manners had already made him some enemies, and a greengrocer, one of the governors, had already made up his mind against him. When Abernethy on his round called at the shop, the greengrocer called out, "All right, Mr. Abernethy, I know what you're after. It's no good your coming to me. Now what do you want?" "Three pen'orth of your plums, please, and wrap them up quick," replied the ready surgeon, and left his antagonist to make the best of it he could.

AMERSHAM.—The soi-disant Medico-Electric Company is a sham, and has nothing medical about it; and the "medical attendant" referred to has, we have ascertained, purchasable diplomas which are not recognised in this country.

DR. MCCAW (Washington).—In reply to your enquiry the Pathological Society of Dublin was merged, together with the Surgical and other societies, into one corporate body under the title of the Royal Academy of Medicine at the end of 1882, since which the transactions have been issued in one yearly volume of the combined societies. This will explain why you have received no "Transactions of the Pathological Society" since 1882.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MAY 8th.

DERMATOLOGICAL SOCIETY OF LONDON (11 Chandos Street Cavendish Square, W.).—5.15 p.m.: Meeting.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m.: Lecture:—Prof. W. Wright: The Prehistoric and Early Historic Inhabitants of England (with lantern slides).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. P. L. Daniel: Clinique. (Surgical). 5.15 p.m.:—Lecture:—Dr. J. Horne: Foreign Bodies in the Ear, Gullet and Air Passages.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—Cliniques:—2.30 p.m.: Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Out-patient (Dr. Whipham).

THURSDAY, MAY 9th.

BRITISH GYNÆCOLOGICAL SOCIETY (20 Hanover Square, W.).—8 p.m.: Paper:—Dr. A. E. Giles: Observations on the Surgical Treatment of Inflammatory Diseases of the Uterine Appendages based on a Series of 120 Cases.

HARVEIAN SOCIETY OF LONDON (Hospital for Paralysed and Epileptic, Maida Vale, N.W.).—8.30 p.m.: Clinical Evening. Cases will be shown by Dr. L. Guthrie, Dr. W. T. Harris, Dr. C. Singer, and others.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. R. Hutchison: Mucous Colitis.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques: Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson). 3 p.m.: Medical In-patient (Dr. Chappel). 4.30 p.m. Demonstration of Medical Cases (Dr. Leslie).

FRIDAY. MAY 10th.

BRITISH LARYNGOLOGICAL RHINOLOGICAL AND OTOLOGICAL ASSOCIATION (11 Chandos Street, Cavendish Square, W.).—4.30 p.m.: Cases and Specimens.

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W).—Papers:—Mr. Sherren: Gastro-enterostomy for Chronic Gastric Ulcer: Healing of Ulcer Verified at Post-mortem Examination 28 months later. Dr. H. French and Dr. M. G. Louisson: Upon the Extent to which Widal's Reaction persists after Recovery from Typhoid Fever. Dr. L. Guthrie and Dr. W. d'E. Emery: Precocious Obesity and Hirsuties with Hypernephrosis.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m.: Lecture:—Prof. W. Wright: The Prehistoric and Early Historic Inhabitants of England (with lantern slides).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Dr. StClair Thomson: Clinique. (Throat).

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—9.30 a.m.: Clinique. Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. Leslie).

Vacancies.

The Hospital for Sick Children, Great Ormond Street, London, W.C.—House Surgeon. Salary £20, washing allowance £2 10s., with board and residence in the Hospital. Applications to Stewart Johnson, Secretary. (See advt.)

Bradford Children's Hospital.—House Surgeon.—Salary £100 per annum. Applications to C. V. Woodcock, Secretary, Bradford.

West Suffolk General Hospital, Bury St. Edmunds.—House Surgeon. Salary £100 per annum, with board and lodging. Applications to the Secretary.

Cuninghame Combination Poor-house, Ayrshire.—Medical Superintendent. Salary £300 per annum, with house, fuel, light, vegetables, and laundry work. Applications to Wm. Gray, Secretary, 5 Montgomerie Street, Ardrossan.

Wandsworth Union Infirmary, St. John's Hill, near Clapham Junction.—Junior Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

Appointments.

FINZI, NEVILLE S., M.B.Lond., M.R.C.S., L.R.C.P., L.S.A., Medical Officer in Charge of the Electrical Department, Metropolitan Hospital, N.E.

FISHER, H. R., M.B.Cantab, Certifying Surgeon under the Factory and Workshop Act for the Fillongley District of the county of Warwick.

GRIMBLY, RICHARD HENRY, M.R.C.S., L.S.A., Medical Officer for the Ippledon District by the Newton Abbot (Devon) Board of Guardians.

HARMER, JOHN D., M.B., Ch.B.Edin., House Surgeon at the Royal Devon and Exeter Hospital, Exeter.

HOWELL, ALFRED, M.D. Lond., Honorary Assistant Physician to the Cardiff Infirmary.

KELLAS, ARTHUR, M.B., Ch.B., D.P.H.Aberd., Resident Medical Officer at the Aberdeen Sick Children's Hospital.

MCELWAINE, THOMAS, L.R.C.S. and P. Edin., L.F.P.S. Glasg., Police Surgeon for the Borough of Devonport.

RUDGE, FREDERICK HENRY, L.R.C.P.Lond., M.R.C.S., House Surgeon at the Torbay Hospital, Torquay.

SHARP, ALEXANDER D., M.D. Brux., F.R.C.S. Edin., Consulting Surgeon for Diseases of the Ear, Nose, and Throat at Noble's Isle of Man Hospital.

STEWART, J., M.B., M.S. Edin., Certifying Surgeon under the Factory and Workshop Act for the Beith District of the county of Ayr.

TAYLOR, A. E., M.B., M.S.Edin., Honorary Physician to the Cardiff Infirmary.

Births.

DUNNETT.—On May 5th, at 7 Ascott Avenue, Ealing, Agnes Dunnett wife of Lionel Francis Dunnett, of a daughter.

HEGGS.—On April 30th, at Toronto House, West Bromwich, the wife of Raymond Mitchell Heggs, L.R.C.P.Lond., M.R.C.S., of a son.

MATTHEWS.—On April 30th, at Holly Lodge, Crawley, the wife of Sidney Philip Matthews, M.R.C.S., L.R.C.P., of a daughter.

THOMPSON.—On April 27th, at Riverbank, Sunbury-on-Thames, the wife of Frank Thompson, M.R.C.S., L.R.C.P.Lond., of a son.

VISGER.—On April 30th, at Elm Lodge, Clevedon, the wife of Charles Visger, M.R.C.S., of a daughter.

Marriages.

ATKINSON—BURD.—On May 1st, at Church Stretton, Thomas Dinham, eldest son of the late William Stephen Atkinson, M.A., to Emily Mabel, daughter of Edward Burd, M.D., of Shrewsbury.

DEWEY—WHITE.—On May 4th, at St. George's, Hanover Square, Edward William Dewey, M.R.C.S., etc., of Kingston Crescent, Portsmouth, to Annie Elizabeth Langley (Nancy), second daughter of the late Charles William White, of Northampton.

HARTHAN—SLATER.—On April 30th, at All Saints' Church, Evesham, George Ezra Harthan, M.B., B.C., only son of Ezra Harthan, of Sandbach, Cheshire, to Winifred May, eldest daughter of the late John Samuel Slater, M.R.C.S., of Evesham.

MORTON PALMER—RUSSELL.—On April 30th, at Streatham Parish Church, London, F. W. Morton Palmer, M.A., M.B., B.C. (Cantab), of Teignmouth, Devon, elder son of F. J. Morton Palmer, M.B., of Streatham, to Gertrude Eleanor, daughter of Alfred Russell, of Walsall.

Deaths.

DAVIDSON.—On April 30th, at 4 Streathbourne Road, Balham, Frederick Montgomerie D. Davidson, L.R.C.P., etc., aged 80.

HIDES.—On April 26th, at Teddington, Mary Rosa, wife of Henry Hides, M.R.C.S.E., L.S.A., late of Ham, Surrey, aged 83 years.

MACREADY.—On May 1st, at "Elmbank," Cumberland Park, Acton, Jonathan F. C. H. Macready, F.R.C.S., aged 57 years.

PATERSON.—On April 28th, at the London Hospital, from pneumonia, following operation, Walter Hugh Paterson, M.D., of Elmer House, Grantham.

WINKFIELD.—On May 3rd, at Hove, Brighton, Rosalie Anna, the beloved wife of Alfred Winkfield, M.A., F.R.C.S., of Beaumont Street, Oxford.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIV. WEDNESDAY, MAY 15, 1907. No. 20

NOTES AND COMMENTS.

Prince of Wales' General Hospital.

THE trouble taken by the members of the Royal Family in supporting the many charitable institutions of the Metropolis, is real and genuine, and contrasts very favourably with the idle *bonhommie* of their predecessors. They give their work unsparingly and ungrudgingly, and it is not their fault if the funds available for hospital resources are not ample. Indeed, if the Royal Family had no other *raison d'etre* than that of keeping alive the charitable instincts of the nation, their existence in the most democratic State would be amply justified. An interesting instance of the progress of humanitarian sentiment in the community is supplied by the fact that whereas princes used to be chiefly honoured by having regiments called after them, now they are proud to have hospitals bear their name. The latest example of this tendency occurred last week at Tottenham, when the Prince of Wales, in opening the new wards of the hospital, graciously announced that at the request of the Princess Louise, the President of the Institution, and the Governors, he had given permission for the hospital to be rechristened after himself. In future, then, the Tottenham Hospital will be known as "The Prince of Wales' General Hospital," and under this proud style no doubt its supporters and staff will feel called on to make their most strenuous efforts to show that their young institution is in no wise behind its older compeers in vigour or usefulness. As a post-graduate school it has a good chance of going far.

Red Lung Balsam.

THE patent medicine duties, as we have frequently pointed out, are not only petty, in that they bring but an inconsiderable sum into the Exchequer, and misleading, in that people think that the Government stamp affixed to bottles guarantees the contents not to be injurious, but also are positively vicious in that they imply that the medicine is remedial as regards the complaints specified. The law, in fact, stipulates that the duty is payable for a preparation that claims by advertisement or label, to be beneficial for the prevention, cure, or relief of any disorder, ailment, or complaint incident to or in any way affecting the human body, and although, of course, the Government take no responsibility in the matter, the fact that they receive money in respect of the claim, and the claim only, makes them morally *particeps criminis* if an unworthy medicine is foisted off on the people. An amusing instance of the *impasse* to which this ridiculous law may lead was provided by an Excise case at the Keighley Police Court the other day, when a patent medicine vendor was summoned for selling his wares without a stamp. The defence was ingenious. The maker called his stuff "Red Lung Balsam," and he claimed that this description did not recommend the medicine for any specific complaint of the human body, and, indeed, it is likely he would have established his position if he had not put a label round the cork of each bottle, saying "Try our Poor Man's Friend for Coughs and Colds." After much deliberation the magistrates decided to convict, but on application have stated a case for the High Court.

Quack, M.B.

THE modern quack appears to be developing from the original stage of a vagabond in the market-place to that of the frock-coated and top-hatted scion of latter-day civilisation. A gentleman of this type was, thanks to the Medical Defence Union, brought within the clutches of the law at Hyde last week. True, he frequented the market-place and addressed the assembled multitudes, but his garb was said to be that of an "orthodox doctor," an expression which seems to imply that a doctor should be judged not by his fruits but by his coat. A woman who gave evidence said that she consulted the accused for indigestion, and paid him a guinea for two boxes of pills and a prescription. The latter certainly suggested the orthodox doctor quite as much as the coat, for it consisted of: "Tincture of gentian, 2 drs.; bicarbonate of soda, 2 drs.; sal volatile, 3 drs.; infusion of colombia (*sic*), 8 oz.; one tablespoonful three times a day." Indeed it would form an interesting matter for calculation as to how many guineas have accrued to orthodox doctors from that or similar prescriptions. However, the gentleman in question, it was said by counsel, so far exceeded the bounds of truth as to describe himself as "M.B." and "M.P.S.," and by his assumption of the former title, the Medical Defence Union were able to prove a clear violation of the Medical Act. The satisfactory penalty of £5 and costs was obtained in each of three cases, together with three guineas for the advocate's fee, so that it may be hoped a cold douche has been put on one more impostor's pretensions. From his own statements, however, he seems already to have amassed a comfortable fortune.

Fine for Family Prescription.

DEEP as is the moral responsibility entailed on medical men by the giving of misleading or faulty prescriptions, it would be very difficult, we fancy, to bring a doctor within the pale of the law for the commission of a pure error. Such, however, is not the case in Belgium, where, according to the *Pharmaceutical Journal*, a medical man recently prescribed fifty grammes of glycerine and carbolic acid, without stating the strength, or, apparently, the purpose for which it was intended. The pharmacist to whom the prescription was presented, was not able to communicate directly with the prescriber, and he, imagining that the preparation was wanted for dilution into a lotion, supplied a mixture containing equal parts of the constituents. As a matter of fact, the preparation was intended for the washing of an infant, and the wretched child was so badly burned that it died. The doctor and chemist were consequently both summoned in the police court, and each fined 300 francs. They appealed, but the verdict was confirmed by the higher court, and in the case of the doctor the fine was raised to 600 francs. Although the medical man's carelessness was culpable, the neglect of the pharmacist to obtain confirmation of the prescription before dispensing it, seems to us to form a far more serious fault. We hardly believe that under the circumstances the former would have been held criminally guilty in England, though his pocket would probably have been severely seared in a civil action.

Cats, Rats, and the Plague.

SINCE the relation of the rat to the dissemination of plague has become part of recognised knowledge, the Government of India have had some firm ground to go on in striving to prevent that disease. The question of rat extermination is now, it seems, to be taken up *con amore*, and as a first step an order has been placed at home for the expatriation of a hundred cats. When one considers the size of India and the number of rats to be dealt with, the hundred cats are likely to have a pretty busy time before they produce an appreciable impression. Or perhaps the spirit of economy that is abroad has taken the Indian Government also, and they have confined their purchase to a single hundred for the same reason that the Sheffield councillor advocated the restriction to two of the number of gondolas for the lake. Indeed, if the ordinary British animal be chosen for the purpose a very sensible addition to the feline staff should be realised before the end of the voyage.

LEADING ARTICLE.

A STANDARD FOR BREAD.

IT is somewhat curious that there is no fixed standard, either as regards its purity or its nutritive value, for so staple an article of food as bread. In view of its national importance the whole question seems not to have received the attention it deserves at the hands of the medical profession and of those concerned in the preservation of the national stamina. It is vain to deplore the physical deterioration of a people if at the same time we neglect the control of its staple foodstuff. An attempt to supply this lack of specific interest has been made by the Bread and Food Reform League, a purely uncommercial and non-political association organised to direct attention to the great importance of the questions involved and to provide the healthy nutrition of the people. Readers will learn with some amount of relief that in this particular instance the matter is discussed without the advocacy of any special system of diet. If in dealing with bread the reformers here and there lapse into the extravagance of enthusiasm, it nevertheless seems clear that in some points, at any rate, they are able to establish their claim to serious consideration. There is no need in a medical journal to remind readers that wheat flour is made from the interior of wheat grains and contains the greater proportion of the starch and most of the proteid. Whole flour, on the other hand, is made from the whole grain after exclusion of the husk, and thus contains not only the white interior of the grain but also its harder and browner outer portions. Whole meal contains one to two per cent. more proteid than the best white flour, but that advantage, under ordinary conditions of preparation, is counteracted by its less ready digestibility. Brown flour is a third variety which contains in addition a certain amount of bran, the cellulose of which irritates the alimentary canal, whereby it acts as a mild laxative. That there must be considerable difference in the nutritive value of bread made from these variously-prepared flours and meals is evident. Magendie's experiments long ago showed that dogs fed on white flour died at the end of fifty days, while those fed on whole-meal bread were healthy and vigorous. Miss May Yates, the devoted secretary of the League, has issued a pamphlet describing and commenting upon the certain experiments on the digestibility and nutritive value of bread carried out at the University of Minnesota, U.S.A. That lady is naturally somewhat jubilant at finding a confirmation of one of the League's previous statements that most people can digest the whole of the wheat grain if it be ground to a uniform very fine quality from properly selected wheat. Milling machinery has of late years been so perfected that there is now no difficulty in securing wholemeal flour in the requisite state of fine division. The results of the Minnesota experiments show similarly it is essential that the whole meal should be ground and re-ground until it will all pass through a fine sieve, and thus pass into a state of fine division which will enable the gastric juices to act in all the nutrients. It is not so much a matter of the varying digestive powers of different individuals as the form in which the grain is ultimately introduced into their stomachs. In addition to this highly practical step of advocating the use of finely ground whole wheat meal, the League has recommended the use of a bread containing the germ, middlings and sharps, or about 82 per cent. of the grain instead of about

75 per cent. It is obvious that the nutritive quality of the bread consumed by the poorer classes should be maintained at a good standard. The popular verdict at present is overwhelmingly in favour of white bread made from white flour. The reason for the preference is to some extent, as already pointed out, due to its more attractive appearance. The main objection to brown bread, however, is undoubtedly due to its indigestibility. If by the simple method of finer grinding advocated by the League the objection to more nutritive whole-meal bread can be overcome, a valuable service will thereby be rendered to the public by informing them on that head. It is in the power of the Government to initiate a simple but far-reaching reform in Poor Law dietaries by drawing the attention of local authorities to this point. Then, again, there is a large field in the bread supplied to our soldiers and sailors. Lastly, the Government will find a vast and valuable reform awaiting them in the substitution of a wholesome and scientific bread for the coarse product now supplied to the prisons of the United Kingdom. If there be one thing more than another out of touch with the humane and scientific tendencies of the age it is the neglected matter of prison dietaries. One of the laudable objects of the Bread and Food Reform League is to secure the standardisation of bread, whereby public analysts and health authorities may be provided with a proper basis of control. On that and other grounds the efforts of the League are worthy of cordial support in its single-minded efforts to promote the healthy nutrition of the people.

CURRENT TOPICS.

The Medical Defence Union.

THE annual report of the Medical Defence Union will be presented to members at the Annual General Meeting at Manchester on the 16th instant. It presents the record of progress and success to which the medical public has become accustomed. As the first of the professional defence societies the Union has triumphantly vindicated the necessity for its existence. In the year 1896 the members numbered 3,832 against 7,092 in 1906. It is perhaps not altogether satisfactory to find that in 1896, with 153 cases to Mr. Hempson, the solicitor to the Union, the law costs were £981 9s. 4d., while in the latter year with 193 cases the amount expended in that direction reached £2,208 13s. 3d. There may, therefore, be special reasons why, in spite of only a trifling increase of law cases in 1906 and with five hundred more members the average cost per head should have advanced to 6s. 1d. in that year as against 5s. 2d. in 1905. No Society, however strong and flourishing, can afford to disregard figures of that kind. Unless expenses are kept at a duly proportionate level there will be no chance of accumulating money. We by no means agree with the remark on page 9 of the report to the effect that "the Union can never hope to have a large reserve fund at its disposal; the very small subscription of members makes this impossible." The obvious criticism suggests itself that it will be impossible so long as law costs, a variable and controllable factor, are allowed to increase unduly in proportion to additions to income. Then, again, the holding of the Annual General Meeting of the Union in a provincial town is hardly calculated to secure a proper control of the affairs of the Society by members. Apart from these few points we have nothing but congratulations to offer the Union on its record of work for the past year. The Union, again, had the courage to protest against the unsatisfactory nature of the penal procedure of the General Medical Council. As the report observes, charges against practitioners are so carefully made that the fact that the complainants are the Medical Defence Union should be a guarantee of the seriousness of the complaint. It is disquieting, therefore, to learn that in one such case a member of the profession found guilty of infamous conduct in May had his name restored to the Register in the following November, without any further inquiry, by the General Medical Council. The report of this important professional body deserves the careful perusal of all who are interested in medicine in its social-legal aspects. The position attained by the Union after twenty-two years of strenuous and devoted work suggest that similar germs of practical organisation may be lying dormant elsewhere in the life of the medical profession.

Palatial Paupers.

THE Local Government Board appears to be awaking to a sense of its duties as regards the active control of Poor Law administration. Their auditor's inquiry into the West Ham Guardians' proceedings resulted in the disclosure of shameless peculation and jobbery that emulate the iniquities of the notorious Tammany ring in New York. The Whitehall authorities have followed up their success in the East End of London by a further investigation in a western suburb. On Thursday last an inquiry was opened by a London Government Board Inspector upon the cost of the new workhouse erected for the district mentioned at Wormwood Scrubbs. It was stated by counsel that the total expenditure had been £261,526, which worked out at the enormous figure of £335 per bed. The only instance that we can recall is that of one of the Metropolitan Asylums Board hospitals, but that did not approach the Hammersmith high-water mark by a long way. As counsel pointed out, thousands of hard working families of eight members, or even more, lived in small houses which had cost far less than the £335 expended on the space for each pauper in the institution under inquiry. The heating apparatus had cost at the rate of £3 per head, and the cost of supplying electricity was £2 to £2 10s. per pauper per annum. One of his most extraordinary allegations, however, was that a system of duplicate wiring had been introduced which was actually rejected some years ago at Buckingham Palace on the score of expense. While there is justification for the claim of decent and humane treatment of poor law inmates, it is nevertheless absolutely unfair to ratepayers to saddle them with the cost of providing palatial quarters for persons who are not benefited by a costly and luxurious environment. It is difficult to surmise what direct benefit can be conferred upon anyone by this sort of vicarious extravagance, unless, indeed, it be those whom it would not be well to mention at this stage of the proceedings.

The Sequel to the Ealing Scarlatina Case.

It is now nearly a year ago since Mr. and Mrs. Crier sued Dr. J. Hope and Dr. J. B. Currie, of Ealing, for negligence whereby Mrs. Crier contracted scarlet fever during her confinement. After a trial of five days a verdict was returned in favour of Dr. Currie, and this was confirmed on appeal to the higher courts. Recently the two medical men concerned brought an action in the King's Bench Division against Mr. Crier for £28 13s., being fees for attendance on Mrs. Crier while she was suffering from scarlet fever. The plaintiff's case was conducted by the London and Counties' Medical Protection Society. Dr. Currie stated that he had not been attending scarlet fever cases at the time, but had called in to see certain patients, and had notified them to the authorities and advised their removal to the isolation hospital. He disinfected himself before attending Mrs. Crier. The learned judge naturally refused to permit the question of negligence to be tried over again, and submitted the present question as simply one of contract. A verdict in favour of plaintiffs was given to the amount of £21 15s. The case is one of special interest and importance to general practitioners, inasmuch as a verdict against the medical men in the first trial would have rendered attendance upon confinements out of the question for those engaged in ordinary practice, to say nothing of the wider question of the communication of infection.

United Service Medical Society.

The formation of a Medical Society to include all branches of the Army and Navy services, including the Indian Army and the Auxiliary Forces, is an event of some importance. For one thing, it is quite in line with the spirit of reform that is now afoot at headquarters. At the beginning of the present month a United Service Medical Society was formally created at a meeting held at the United Service Institution, under the presidency of Inspector-General Ellis, Director-General of the Medical Department of the Navy. Its scheme is comprehensive, and includes :—(1) The furtherance of sciences which bear upon the preservation of health of forces afloat and ashore, at home and abroad, in war and in peace. (2) The study of diseases incidental to the life of sailors and soldiers under the varying conditions of climate, locality, and circumstances to which they are exposed in the performance of their duties, and the treatment of the same. (3) The study of organisations, methods, and apparatus for the amelioration of the condition of the wounded in war. (4) All matters which come within the scope of the technical duties of naval and military medical officers. The chairman was unanimously elected President of the Society for one year, and it was determined to hold the meetings at the Royal Army Medical College. Fleet Surg. W. W. Pryn and Lieut.-Col. C. H. Melville were appointed hon. secretaries, and Lieut.-Col. D. Wardrop hon. treasurer. It was announced that the Society's affairs would be managed by a council consisting of the president and the following officers elected by the Society :—Fleet Surgs. Craig and Dalton for the Navy; Major Holt and Lieut.-Col. Cottell for the Army; Lieut.-Cols. Sir R. Havelock Charles and Freyer for the Indian Army; Lieut.-Cols. Sir J. Clark and V. Matthews for the Auxiliary Forces. There will also be four *ex officio* members—the Directors-General Navy and Army Medical Services, the president of the Medical Board at the India Office, and the commandant, Royal Army Medical College.

Medical Men and Publicity.

In commenting recently on the manifesto on the use of alcohol which appeared in a contemporary, we expressed our surprise at its apparent spontaneity, and wondered for what purpose the document sprang into existence. As we guessed, it was not altogether as spontaneous as it appeared, and it has now been made known that its only begetter was Mr. Ernest Williams, a journalist specially interested in economic questions. The signatures were procured, it appears, and the manifesto issued in the interest of the alcohol industry. Innocent as the distinguished signatories may have been of this object, we can hardly congratulate them on the dignity of the position in which they have been landed. The views they have put forward may or may not be justified, but both the occasion and the manner of promulgating them are unfortunate. We regret to notice, indeed, of late years a greater tendency on the part of medical men to address the public through the columns of the newspapers, sometimes on purely medical matters, at other times pretending to express orthodox medical opinion on matters of general interest. The device adopted by a professional contemporary a month or two ago of distributing advance proofs of their issue to the daily papers, called forth from the contributors but very half-hearted disclaimers. This craving for publicity is an unpleasant phase of professional life, and we trust it is one which will soon disappear.

Motor-Car Taxation.

It is one of the minor injustices that medical men labour under that they should be compelled to pay the carriage-tax, for a vehicle is not only absolutely necessary for the pursuit of their profession, but also it can be clearly shown that for practical purposes its use is restricted entirely to business purposes. All trade-vehicles are exempt from this carriage-tax, and if a medical man were to paint his name on or attach a number to his brougham, there is no doubt he would be exempt from the tax. But even if the practice were sanctioned by the General Medical Council—

which is exceedingly doubtful—all tradition and usage would be against it, and in a practical work-a-day world it would be impossible. The Collectors of Inland Revenue know this well, and they trade on the necessities of the medical profession in a very mean way to procure them a regular source of revenue. It is all the more necessary that when the question of the taxation of motor-cars comes up in the near future, as seems more than likely, that strong representations should be made with regard to the medical man's position. Sir Henry Craik, who sits for the Aberdeen and Glasgow Universities has promised to see to the matter on behalf of his medical constituents, and if properly supported, it can hardly be doubted that he will obtain this small but important measure of justice.

The Health of Dublin.

THE death-rate of the Dublin Registration Area for the week ending April 27th, reached the extraordinary figure of 35 per 1,000 of the population per annum, being, in fact, equal to the latest recorded rate in Calcutta. In Calcutta, moreover, plague and cholera are both raging, whereas in Dublin there is no epidemic existing. The rate in Dublin for the week mentioned was by far the highest of any European city in the Registrar-General's list. Nevertheless, as far as the public can learn, the Public Health authorities remain inert, and we have been unable to discover in the daily papers a single reference to the present appalling mortality. The Dublin press and public seem to be in some strange way hypnotised so as to pay no heed to the condition of the city as regards sanitary matters. The Local Government Board Report, to which we referred some months ago, made clear that the recommendations of the Viceregal Commission of 1900 had been treated with contempt by the Corporation, but up to the present no steps have been taken to atone for this criminal negligence. The attitude of the health authorities toward the outbreak of cerebro-spinal fever also is not one to encourage confidence. Although deaths from the disease are still being registered, as far as the public can learn there are no cases being notified to the health authorities.

Milk for the Children's Hospitals.

A CONFERENCE was held a week or two ago between representatives of the various children's hospitals in London, in order to arrive at some arrangement which would safeguard the nature of the milk supply of the hospitals. Several resolutions were adopted providing, among other things, that the milk should be of a certain quality and should come from farms registered with the hospital authorities. The farms should be open to inspection at all reasonable times, and the cows supplying the milk should be certified as healthy every three months by a veterinary surgeon. Other precautions are to be observed as to the method and time of transit from the farm to the hospital. There is no doubt that it is of the greatest importance that children in the city hospitals should be provided with pure, good milk, and the restrictions the hospitals propose to impose seem well adapted for the purpose. The curious thing is, indeed, that such restrictions have not already been in force. It would appear, however, from the publicity given to the present movement as if this were the first time the question had been considered. If it be so, there has been a culpable slackness on the part of the hospital authorities.

PERSONAL.

IT is officially announced that Princess Henry of Battenberg has appointed Dr. Alfred James Rice Oxley to be a Physician-in-Ordinary to her Royal Highness.

SIR VICTOR HORSLEY has been elected honorary member of the Russian Surgical Society.

MR. BLAND-SUTTON, F.R.C.S., delivered an address on "The Problem of Cancer," at the Institute of Hygiene yesterday, the 14th inst.

OUR Scotch correspondent writes us that Lord Mount Stephen, whose previous acts of munificence will be remembered, has just given another £10,000 to the Aberdeen Royal Infirmary.

IN connection with the celebration of their golden wedding, Dr. and Mrs. Stretton were last week presented by the Kidderminster Infirmary Committee with a silver rose-bowl, in the presence of nearly 500 personal friends.

DR. DAVID LOWSON, M.D., late surgeon of the Hull Royal Infirmary, who was awarded the Albert Medal of the First Class for sucking the tracheotomy tube from a patient with diphtheria, left estates valued at £10,146.

DR. DONALD MACALISTER, President of the General Medical Council, will take the chair at the opening of the next session of the Council on Tuesday, May 28th, at 2 o'clock, when important business will be proceeded with.

MEDICAL men resident in Greenock have formed a new incorporation to be known as the Greenock Faculty of Medicine. Sir Hector Cameron, M.D., Glasgow, has been appointed president, and Dr. William Allan is secretary.

DR. HERBERT W. G. MACLEOD, who has travelled extensively in the Tropics, is announced to read a paper in London this evening at the Society of Arts, on "Sleeping Sickness." The chair will be taken at 8 o'clock, and members of the medical profession will be welcomed.

SIR ALFRED JONES, president of the Liverpool School of Tropical Medicine wired Dr. Kinghorn and Mr. Eustace Montgomery, on their departure:—"Again good-bye and best wishes. May you achieve the success of your heart, and so benefit the world by your great work of humanity." They replied:—"We thank you for good wishes, and will do our best." These gentlemen will be away in Central Africa for two years.

DR. F. M. SANDWITH, Lecturer on Tropical Diseases at St. Thomas's Hospital, who was appointed Gresham Professor of Medicine to Gresham College, London, in the place of Professor Symes Thompson, deceased, will deliver his first course of lectures at the College to-day, Thursday, and Friday, at 6 p.m.

A Clinical Lecture
ON
CLIMACTERIC FLOODINGS.

By PROFESSOR ALFRED J. SMITH, M.B., M.Ch., F.R.C.S.I.,

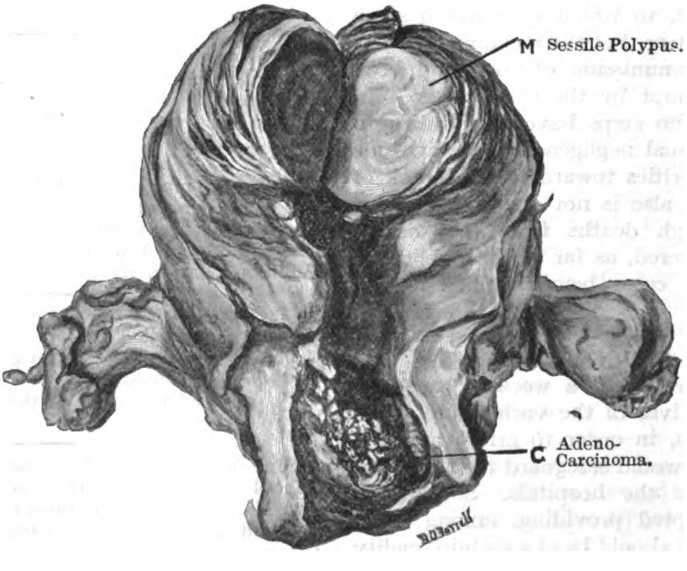
Gynæcologist to St. Vincent's Hospital, Dublin; Examiner in Midwifery, Royal University of Ireland.

There seems to be a more or less general impression that floodings or irregular hæmorrhage must of necessity occur at the climacteric.

Consequently when a patient consults her doctor, and states that her age is 46, that she has noticed her changes becoming heavier and more frequent, most practitioners are content to adminster some astringent mixture and send the patient away with the assurance that she is suffering from an ailment incidental to the change of life, little heeding the disastrous consequences of their action. This attitude of mind is unscientific. The principle of neglecting to make the essential local examination has cost the lives of many valued patients; it is a great blot in modern gynæcology.

To deal *in extenso* with this important question would be beyond the scope of an ordinary lecturer. I may begin by stating that the whole subject of severe uterine hæmorrhages occurring near the menopause requires overhauling; many remarkable cases have been recorded in our literature of late, where the pathological findings have been almost as remarkable as the theoretical construction advanced in explanation of the hæmorrhages. This confusion lends an attractive interest to the subject.

I can best illustrate my contention by bringing under your notice to-day three cases that have recently come under my observation, and I am fortunate in having the pathological specimens for your inspection. The graphic description of the pathological findings made by Dr. Farrell, pathologist to St. Vincent's Hospital, will do much, I hope, to interest you.



Case II. showing Sessile Polypus and Adeno-Carcinoma.

Case I.—C. H., æt. 48, first consulted me for sheddings, which came on without any warning, and so heavy that the blood would stream down on the floor. From the loss of blood and the anxiety brought about by her dread of the hæmorrhage, made her condition very pitiable. She told me that for the past eight years her changes were heavy, but that for the past six months she knew not the day or the hour when a gush of blood would come. She saw her regular medical attendant, who prescribed ergot and iron mixtures for her. He also gave her ergo-apiol and styptol; in fact, he exhausted all the well-known remedies without benefit.

When I saw her she was quite blanched and run down. Bi-manual under ether gave uterus normal in position, slightly larger than normal; elastic in feel, rather like that of a pregnant uterus; but it did not contract on continued manipulation. On passage of sound blood squirted out from the os in a jet and was so alarming that I had to hastily plug the uterus and postpone investigation. One thing was clear to my mind, the necessity of a radical operation. But before attempting it, I deemed it advisable to build the patient up with tonics and rest. It was almost three weeks before I felt justified in performing a laparotomy and removing the uterus.

Cavernous Angioma of the Uterus.

The pathological condition consists of dilated spaces generally scattered throughout the uterine wall, in many places they are collected into groups, particularly in the centre of the wall and under the mucous coat. The disease chiefly occupies the posterior part of the organ, where, in two places, it almost reaches the peritonial surface. Much of it projects into the uterine cavity, pushing the connective tissue and mucous coat in front of it; in this place the spaces are numerous, though small, giving it a somewhat spongy appearance. The spaces vary in size, the majority being about 2 to 3 mm. in diameter. Two or three are of irregular shape and of remarkable size, about 2·5 cm. in longest measurement, and 2 cm. in greatest diameter and depth.

The cavities are lined by smooth endothelium of a whitish colour in the small spaces, though brownish in the large, where the lining membrane is thrown into folds of varying sizes. The consistency of the tumour is the same as that of the uterine wall, though softer and more elastic over the larger spaces. Around each of the cavities there is a more or less dense tissue running in bundles, holding some of the spaces open and constricting others. The fibrous tissue in places is arranged in whorls, some of which contain blood-vessels.

Angiomas of the uterus are extremely rare ; I cannot find any reference to more than two well-authenticated cases. Hence this specimen is of more than ordinary interest.

Case II.—N. S., æt. 40, had been suffering for some months from heavy menstrual discharges. Her physician told her it was quite natural to expect such irregularities, as she was coming to the change of life, and prescribed some astringent mixture. Her condition becoming worse, I saw the patient. A prune juice discharge was coming from the vagina, there was no offensive odour present. Examination under ether revealed a Sessile fibro-myomatous polypus growing from the fundus. Before attempting to remove the polypus by morcellation, a finger was introduced into the uterine cavity to accurately map out the tumour. It was fortunate I did this, as a small ulcerating patch was discovered on the posterior wall of the cervical canal, as shown in the drawing. A fragment was removed, the microscopic finding being adeno-carcinoma with active mitotic changes.

Case III.—M. B., æt. 47, was sent up to hospital in a blanched condition. She complained of losing heavily. Not only was her menstruation heavy, but that latterly sharp hæmorrhage came on in the interval between the ordinary menstrual periods.

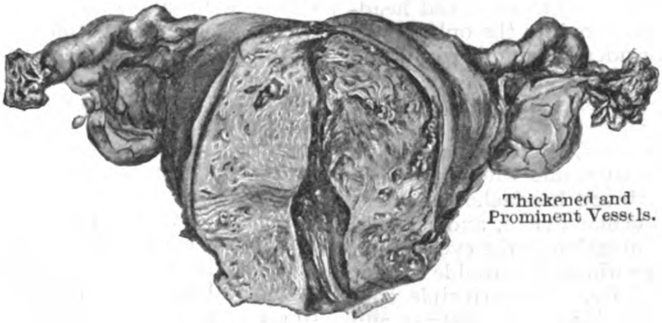
Her physician consoled her at first, that such heavy flows and irregular discharges were to be expected, that a bottle or two of a special mixture, assisted by rest in bed and hot vaginal douch would soon have her all right.

Both patient and doctor were soon disillusioned. Another sharp hæmorrhage determined the patient to come to Dublin.

Examination.—On bi-manual, uterus normal in position, somewhat enlarged, with almost a stony hardness. On curettage nothing came away. The diagnosis was made of arterio-sclerosis, and fourteen days' preparatory treatment of the patient was undertaken. The uterus was then removed by ordinary abdominal route.

ARTERIO-SCLEROSIS OF THE UTERUS.

The uterus, after hardening in formalin, measures 9 cm. by 8·5 by 6 cm. The serous surface is smooth and free from adhesions. On section, the uterine wall is thickened and firm, measuring 3 cm. across. The vessels on the cut surface are visibly thickened and prominent, and stand out very distinctly, particularly at the outer part of the uterine wall. The inner portion of the wall is firm, having a homogeneous appearance. The uterine cavity is 6 cm. long. The mucous membrane has a smooth, pale, undulating surface, and is slightly thickened. There are no ovarian changes.



Case III.—Arterio-Sclerosis.

Treatment.—In discussing the lines of treatment I am prevented by my preliminary restriction from detailing the routine treatment of simple uncomplicated cases of climacteric floodings. I must confine any observation I have to make to the types of cases just described—*e.g.*, malignant, arterio-sclerotic and angiomata. A fundamental principle guiding my practice in every case of climacteric flooding is to make a thorough local examination, nothing must be left to chance. A complete bi-manual, if necessary under anæsthesia, must be made ; the great importance of eliminating any possibility of the existence of malignant disease of the uterus by a preliminary curettage and the microscopical examination of the scrapings I insist upon. Much valuable information will be obtained by a digital examination of the interior of the uterus, as was demonstrated in Case 2 above.

Malignant.—Obviously for malignant and angiomatous types there is only one line of treatment for operable cases—panhysterectomy.

Arterio-Fibrosis.—In the aggravated forms of this type you may try all the recognised methods of arresting hæmorrhage—such as posture, curettage, tamponing the uterine cavity with sterilized gauze, or hot douching. You may give internally all the uterine tonics or astringents in the B.P., or the uterine tablets of fashionable pharmacists, but still the hæmorrhage persists. How then may the hæmorrhage be controlled ? Two methods are at present being advocated, *viz.*, hysterectomy and atmokausis. Hysterectomy is the method followed in those cases that came under my notice, and I have been well satisfied with the result. The alternative method is not so well known in this country ; it consists in applying superheated steam generated in a special kettle to the interior of the uterus. This method is known as atmokausis. It was originally introduced by Professor Snegiren, of Moscow, and established upon a firm scientific basis by the work of Dr. Ludwig Pincus, of Danzig ; it is now a well recognised therapeutic measure, being advocated by a number of well-known gynæcologists both on the Continent, America, and at home.

Some points in this comparatively new treatment may interest you. Whenever possible it is better for the operation of atmokausis not to follow immediately on that of curettage. The best results are to be obtained by the use of steam between 110°C. to 115°C. for a short a time as possible, *viz.*, from 5 to 40 seconds. If the steaming is repeated, this should not be done until three to four weeks have elapsed, the length of time during which the action of the steam is to be allowed to continue may be judged by the readiness with which the uterus responds to the stimulus of the heat by contracting ; cases where it is desired to use steam to procure complete obliteration of the uterine cavity it must be used at a temperature of 115°C. for one minute on two occasions, the second application to be made some 15 or 20 days after the first. Rest in bed should be enjoined in all cases until the slough has separated.

Pincus claims for this method a very strong position ; he goes so far as to state that no case of hysterectomy should be performed without at first giving atmokausis a trial. My experience has not been so satisfactory, there always seemed to me to be a great danger of causing occlusion of the internal os. The recent suggestions of Pincus to shield the cervical canal and internal os completely will, I hope, go a long way to prevent this regrettable accident.

The main features then of the three cases are :—The patients were all in or about the climacteric, they all suffered from heavy menstruation and irregular hæmorrhage, and the drug treatment was tried without benefit. Local examinations demonstrate three distinct pathological conditions.

My contention that a thorough local examination is justified, nay, demanded in all cases of hæmorrhage occurring at the menopause, is more than amply demonstrated.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Sir James Barr, M.D., I.L.D., F.R.C.P., F.R.S.E., Senior Physician Liverpool Royal Infirmary Chairman of the Medical Faculty of Liverpool University, President of the Lancashire and Cheshire Branch, British Medical Association. Subject : "The Treatment of Pneumonia."*

ORIGINAL PAPERS.

OCULAR HEADACHES. (a)

By R. PHILIP BROOKS, F.R.C.S.E.

Ophthalmic Surgeon to the Prince of Wales' Hospital, Tottenham.

Gentlemen,—The subject of ocular headaches, in spite of its importance, is one which is only dealt with scantily in text books. Although eye strain, as a cause of headache, is well recognised throughout the profession, one not infrequently meets with people who have suffered for many years from more or less continuous headaches and have been subjected to various treatments without the eyes having been suspected ; and yet an examination of the eyes, followed by proper optical correction, at once gives relief. On the other hand, among the cases of unrelieved headache that are rightly referred to the ophthalmic surgeon, there are a considerable number in which an exhaustive examination of the eyes fails to discover any physical or pathological defect which can be fairly assigned as even a factor in causation. It follows then, that it is by no means always easy to determine whether or not in a given case of continued headache the cause is wholly or partly an ocular defect, and I would urge that a careful examination of the eyes should be made in every case in which the trouble cannot be otherwise accounted for. The principle conditions of the eye which give rise to distress and headache are, firstly, certain errors of refraction which throw an excessive amount of work on the ciliary muscles ; secondly, a want of balance between the external muscles of the globe ; thirdly, what may be called retinal hyperæsthesia.

With regard to the first it must be remembered that the hypermetrope is using his ciliary muscle not only during near work, but also when the eye is focussed for distance and should be at rest. In astigmatism, whether hyperopic or myopic, the strain on the ciliary muscle is even greater, so that it frequently assumes a state of spasm, which only yields after the continuous use of a strong cycloplegic such as atropine. Frequently in this way what appears on first examination to be myopic astigmatism is, after the use of atropine, proved to be hypermetropic astigmatism, or the amount of the apparent myopia is diminished.

Simple myopia of moderate degree which is not increasing, I have not found to be a cause of headache, but inequality of refraction on the two sides, if binocular vision is still maintained, does cause both distress and headache.

Frequently the above conditions exist without there being any symptoms directly pointing to the eye as cause. The pain is most often frontal or brow, but may be in the vertex or occiput. It comes on in the daytime, increases towards night, and is relieved by sleep. It is generally most excessive in the lower degrees of ametropia, 1 or 2 D. of hypermetropia or 0.5 D. of astigmatism, causing more distress than when the error is 3 or 4 D. or more, the reason being that in the former case the ciliary muscle is in a state of constant activity, endeavouring to maintain perfect vision ; while in the latter the impossible has been given up, and the patient is content with less vision. It is in the lower degrees of ametropia that it is frequently difficult to convince the patient that there is anything wrong with his eyes. He has no direct eye symptoms. He protests that his sight is quite perfect, and, as a matter of fact, when tested with the distant types, can often read the normal standard without effort. Such a case then would not be detected unless a special examination were made.

Let us now turn to the external muscles of the eye. Want of balance between the external muscles is less common than error of refraction, but is more likely to cause headache, vertigo, and general distress. Let me explain for a moment what is meant by normal oculo-motor balance. If, with a pair of normal eyes, the gaze be directed upon a distant object, the visual axes are so perfectly adjusted that the images received are thrown upon corresponding portions of the two retinæ and binocular vision results. If now, a screen be placed in front of one eye so that the stimulus of binocular vision is removed, no deviation will occur, nor will any movement of adjustment take place when the screen is removed, provided there is normal balance between the muscles ; and this will be found to be the case in by far the majority of patients examined. When there is a want of balance between the muscles a deviation of the covered eye will occur. The most convenient way to demonstrate and measure the deviation is to place in the screen the cylindrical glass rod introduced by Maddox, and to direct the patient with both eyes open to look at a candle flame at five metres distant. The image of the candle flame seen by the screened eye is converted by the cylindrical rod into a light streak, which cannot be fused with the candle flame seen by the uncovered eye. The screened eye deviates, and if a scale is placed behind the candle flame the amount of deviation may be calculated from the distance between the candle flame and the light streak. Want of muscular balance or heterophoria, as it is called, is due (1) to a muscle or group of muscles being too strong or two weak for the opposing muscle. (2) To the insertion of a muscle being misplaced, and therefore acting at a greater or less mechanical advantage. (3) To defective innervation of a group of muscles.

(a) **An Epitome of a Lecture delivered February 5th, 1907, at the North-East London Post-Graduate College, Prince of Wales' Hospital, Tottenham.**

The most prominent symptoms produced are headache, especially brow pain, coming on towards the end of the day, pain in the eyes, giddiness, nausea, and occasional diplopia. Frequently symptoms which have remained dormant become distressing after a severe illness, or at the time of life when presbyopia begins to show itself. As with errors of refraction, the amount of distress produced is in no way proportionate to the degree of muscular inbalance. Often a considerable amount of excessive convergence (esophoria) or of a tendency to the opposite condition of divergence (exophoria) may exist without causing any distress. It is otherwise, however, when the tendency is for one eye to deviate upwards (hyperphoria). Here a single degree of deviation is sufficient to cause some distress and will require correction. Frequently such people have been to numerous opticians, and have been provided with various spherical lenses without relief; indeed, their symptoms have often been aggravated in this way. Many considerations must be taken into account before correcting heterophoria. Where no distress is caused, no correction is necessary. In some cases the tendency to deviation disappears when the refraction of the eye is corrected; or again, so close is the association between convergence and accommodation that an eye that has long been accustomed to the altered conditions brought about by an error of refraction, may, when that error is corrected, cause distress due to a false heterophoria.

In deciding on the prism, if any, that must be prescribed, besides the direction and degree of the deviation, the state of the patient's muscles must be investigated, and this is best done by finding the maximum prism which the various muscles are able to overcome without diplopia being produced.

Plainly the treatment of such conditions and the prescribing of lenses is a matter which requires a ripe experience based upon scientific knowledge of the conditions prevailing, both in health and disease, and should not be allowed to fall into the hands of those whose business it is to make spectacles. The attitude taken up by many general practitioners, of not touching eye work, is, I think, wrong. The apparatus sufficient for diagnostic purposes is both simple and inexpensive. In a suspected case I would advise the following routine to be carried out :—

(1) An inspection with the mirror of the ophthalmoscope to discover any opacities of the medea.

(2) Patient reads Snellen's test card. Failure of either eye to read the last line ($^{6}/_{6}$) at a distance of twenty feet indicates a defect for further investigation.

(3) If the patient can read about the same with a spherical lens say + 1 D., a diagnosis of hypermetropia can be made.

(4) A cylindrical lens say + 0.5 D. is placed before each eye separately and rotated. If vision is improved, a diagnosis of astigmatism is made.

N.B.—A concave spherical or cylindrical lens will often improve vision by calling the accommodation into use, and are therefore of little value for diagnosis. In such cases a mydriatic must be used unless the patient be presbyopic.

(5) Test the muscles (*a*) for insufficiency of the interni. The patient should converge by following the finger to the tip of the nose (*b*) by Maddox cylindrical rod above described.

INTUBATION OF THE LARYNX
IN
LARYNGEAL DIPHTHERIA. (*a*)

By CLAUDE BUCHANAN KER, M.D., F.R.C.P.

Medical Superintendent of the City of Edinburgh Hospital; Lecturer on Infectious Diseases, Dist. University of Edinburgh.

AFTER referring to the abortive attempt of Bouchut in 1858 to replace tracheotomy by intubation, the author remarked on the fact that while intubation is the operation of election in America, France and most other European countries, it has not many votaries in Great Britain. Its theoretical advantages over tracheotomy are: (1) breathing through the natural passages and diminished risk of pulmonary mischief; (2) a cutting operation is unnecessary; and (3) absence of a scar. No preparation is required, and relief is immediate. On the other hand, after tracheotomy the parts involved get complete rest, and if the tube becomes dislodged it can be replaced by an unskilled person. On account of the different conditions under which patients are operated on statistics are of little value in deciding between the rival operations. It might be thought that tracheotomy would allow more readily of the extrusion of membrane, but large pieces can be expelled through an intubation tabe, and on intubation, also, coughing is more vigorously performed. The danger of plugging the intubation tube is exaggerated, and if a string is attached to it it can be readily removed should it become blocked. Several times, however, the speaker had seen the tube push membrane beyond, and thus block the trachea; this however is rare, and not a fatal accident. The possible infection of the trachea by the dislodgement of small pieces of membrane is a theoretical objection only, and, in any case, has no weight since the introduction of antitoxin. Serum, unquestionably, has rendered possible the good results now obtainable by intubation, as the rapid disintegration of the membrane which follows its use, often makes it unnecessary to do more than tide the patient over two or three days, which can be done more safely by intubation than tracheotomy. Up to three years ago Dr. Ker's mortality rate never fell below 40 per cent. of those intubated—much the same as that of hospitals in which tracheotomy is practised—but great improvement in his results was shown since nasal feeding had been adopted. Prior to this he had depended almost entirely on rectal feeding. About the same time he had adopted vulcanite in place of metal tubes, and these were much better tolerated, and could be worn much longer by the patients. In hospital practice the operation should be postponed as long as possible; Dr. Ker's series of cases were mostly in the third stage of croup—*i.e.*, showing signs of exhaustion and heart failure, when they were intubated. It is well not to interfere so long as the respiratory difficulty remained paroxysmal, because many patients recover in this stage, severe though the paroxysm be. The great thing is to try to give the serum time to act, and to be at hand to operate at a moment's notice. In private practice, of course, early intubation was required. Since 1904 his mortality rate for ntubation was 27 per cent. More than a quarter of the total patients required secondary

---

(*a*) **Abstract of paper read before the Edinburgh Medico-Chirurgical Society, May 1st, 1907** tracheotomy, and of this fraction 55 per cent. died. In only eight cases did tracheotomy succeed where intubation failed. The operation should, however, always be done if intubation does not give relief. Nine patients died in whom only intubation was performed; three of these succumbed from various causes after the tube had been finally removed; five died relieved of the respiratory difficulty with the tube *in situ*, and one died while being intubated, from cardiac failure.

The author thought that the tube should be removed some time between 48 and 72 hours—generally 2½ days. In most instances it is not necessary to replace it. In twelve cases intubation had to be performed twice, in three three times, in one four times, in one six times, in one seven times, and in one fourteen times. If a patient got through the first four hours without difficulty it is rare to have to replace the tube. The tube should be removed in the morning, as the breathing is likely to become worse at night. One satisfactory feature of intubation was that it might only be of momentary duration, tube and membrane being at once coughed up with immediate permanent relief. In his cases the tube was worn for from two days or less, up to twenty-nine days. It is doubtful whether tracheotomy is any use in cases in which the tube cannot be dispensed with, for the difficulty arises again as soon as the cannula is removed. The cause of the obstruction is atrophy of the laryngeal abductors, and adductor spasm.

To intubate dexterously requires considerable practice. The patient ought to be recumbent, to avoid risk of heart failure. It is best to leave the string attached to the tube in position, fixed to cheek with plaster strapping. Banjo string was preferable to silk, as less likely to be bitten through. Extubation is much more difficult than intubation, and the long American tubes cannot be removed by Bayeux's method. The string, therefore, should be left. Steam is useful at first; in bad cases of retained tube open air is preferable. The great difficulty in introducing intubation into private practice is the experience which it demands. Its advantage is that it may be performed early and so relieve the patient of the risk of being left without operation, and with no medical attendant immediately at hand. In severe cases, on the other hand, tracheotomy is probably safer in private. In country practice he would be inclined to intubate every case of laryngeal diphtheria as soon as it was diagnosed, provided the obstruction was not very marked, in which case tracheotomy would be safer.

THE SYMPTOMS, TREATMENT AND SEQUELÆ OF NON-MALIGNANT DUODENAL ULCER. (*a*)

By D'ARCY POWER, M.A., M.B. OXON., F.R.C.S. ENG.

Surgeon to and Lecturer on Surgery at St. Bartholomew's Hospital; Surgeon to the Bolingbroke Hospital.

THE symptoms, treatment, and sequelæ of non-malignant ulcer of the duodenum have hardly received the attention they deserve owing to their frequency and severity. Until about the year 1892 duodenal ulcers were of purely academic interest. They were recognised *post mortem* and their occurrence was occasionally suspected during life, but no attempt was made to treat them surgically or to differentiate them from gastric ulcer. Increasing familiarity with the surgery of the stomach led naturally to a better acquaintance with abnormal conditions in the duodenum. Surgeons dealt first with duodenal ulcers which had perforated acutely: they were then led to interfere in cases where hæmorrhage was the chief symptom; more recently they have concerned themselves with the results of duodenal constriction due to cicatrisation of ulcers in this part of the alimentary canal.

My position as a hospital surgeon has given me numerous opportunities of seeing and treating various cases of duodenal ulcer and I have thought this a fitting opportunity of communicating what I have learnt about them and the opinions at which I have arrived.

Causes.—Nothing is known with certainty as to the causes of ulcer of the duodenum. It is rarely associated with ulcer of the stomach but the causes which produce gastric ulcer probably play a part in causing ulcer of the duodenum. The duodenum, too, is liable to the same inflammatory conditions as other parts of the alimentary canal. Tuberculous and typhoid ulceration are therefore not uncommon. There is no doubt that general septic and pyæmic conditions may be associated with duodenal ulcer and to these causes perhaps is to be assigned the duodenal ulceration found in a certain proportion of patients who have been burnt especially when there has been much suppuration. The experiments made by Dr. William Hunter (*a*) point in the same direction, for he showed that the subcutaneous injection of toluene-diamine into dogs was followed by marked duodenal ulceration, the drug being destructive to the red blood corpuscles, and being eliminated by the liver. There seems to be an ill-defined relation between duodenal ulceration and some cases of interstitial and tubal nephritis, whilst the stress of anthrax infection may fall upon this part of the alimentary canal. A duodenal ulcer either perforates or it does not perforate. If it does not perforate it may lead to hæmorrhage, or it may cicatrise, causing one form of pyloric obstruction.

(A) PERFORATING DUODENAL ULCER.

Perforation.—The subject of a perforating duodenal ulcer is usually a man in the prime of life who assures you that he has either never suffered from any dyspeptic symptoms up to the moment of his sudden illness or has had so little indigestion that he has taken no account of it. Without warning he is suddenly seized with a stomach-ache of such severity that he becomes collapsed at once and sends immediately for assistance. He may vomit, but from the onset he passes neither flatus nor fæces. Examination within an hour or two of the attack shows him lying on his back, afraid to move, his breathing shallow and rapid, his pulse small, regular and quick, but not nearly so much accelerated as his respirations. He looks pinched and haggard, but his temperature is normal. The patient cannot localise the pain, but complains that it is worse along the upper half and down the right side of the abdomen. The abdomen is not distended and is not motionless, though it moves less freely during respiration than it should do. At first it is held rigid and the muscles on the right side are somewhat more tonically contracted than those on the left. It is everywhere tender and tympanitic. The area of liver dulness may not be altered, and there is sometimes a point of maximum tenderness in the right hypochondrium. If no operation be performed, the pain becomes less acute and more generalised than it was at first. The patient rallies from the initial shock and may fall asleep; he loses his pinched appearance, and though the abdomen is still rigid it moves slightly during respiration. If unfortunately the patient is still left untreated, either because an incorrect diagnosis has been made, or because he does not apply for relief, the pain again becomes urgent, but is now felt in the right iliac fossa which becomes especially tender, full and motionless. The patient shows the ordinary signs of peritonitis, he again becomes collapsed, his pulse quickens, his temperature

---

(*a*) "Pathological Society's Transactions," Vol. 41, p. 205.

rises, and he dies usually with a diagnosis of appendicitis.

The errors in diagnosis are quite excusable in those who have not already had to treat a case of perforated duodenal ulcer, and in those who are only called in to see a patient in the later stages. The initial shock caused by the sudden perforation is generally sufficient to indicate that some grave catastrophe has occurred and has overwhelmed the peritoneum. The symptoms are not quite like those of a perforated gastric ulcer, because the duodenal contents are more digested and less acid than those of the stomach, and there is consequently less irritation. The symptoms subside therefore for a time, and the fluid poured out by the duodenum slowly accumulates in the iliac fossæ and more in the right than in the left. The onset of peritonitis demands an examination of the abdomen and, as the patient now locates his symptoms to the lower part of his abdomen, it is easy to treat the case as one of appendicitis.

Diagnosis.—The diagnosis of a perforated duodenal ulcer should be easy but in practice it is often a matter of great difficulty as is shown by the cases I have just quoted. The patient is suffering acute abdominal pain and the attack began suddenly. The history of previous good health, the fact that the abdomen is moving during respiration, the absence of any great amount of rigidity in the abdominal muscles or of any point of maximum tenderness, are all misleading, and make it difficult for the surgeon to believe that the patient is suffering from such a dangerous condition as a perforated ulcer of the duodenum. He may think of a perforating or leaking gastric ulcer, but the symptoms are much less characteristic than he is accustomed to find in this condition, and it is not until he has seen one or two similar cases that the occurrence of a perforated duodenal ulcer is called to mind. The diagnosis, therefore, is too often left in abeyance in the hope that a few hours' delay will render the signs and symptoms more definite. Such advice is likely to prove fatal, for instead of making the diagnosis clearer time only renders it more obscure. The slight clues which could be picked up shortly after the onset when the peritoneum was only affected at the point of perforation are soon masked by the general peritonitis produced by the diffusion of the duodenal contents throughout the abdominal cavity. Delay thus allows the extravasated fluid to gain access to the innermost recesses of the peritoneal folds so that a subphrenic, pelvic or iliac abscess may still further complicate a condition which is well-nigh desperate from the beginning.

When I am called to a patient who has been seized suddenly with intense abdominal pain, without much history of previous indigestion, I ask that he shall not be given morphia, and that his pulse shall be counted carefully and accurately recorded by the same person every half hour. If on my arrival the pulse rate has increased although the patient has been kept at rest and free from disturbing influences, I have no hesitation in advising an immediate exploratory operation, even though the objective signs be very slight.

The escape of gas and liquid as soon as the abdomen is opened prove that a perforation has occurred and the first thought of a surgeon will then be that he is dealing with a ruptured gastric ulcer. The character of the fluid often gives the first indication as to the seat of the perforation. When it comes from the duodenum, it is limpid or bile-stained, free from smell, alkaline and thus wholly different from the extravasated contents of the stomach which often contain undigested portions of food. The fluid from the duodenum is the succus entericus and is, I suppose, the secretion of Brunner's glands. It is sometimes very abundant, and comes welling up from the perforated intestine in quite a characteristic manner. The perforation is usually small, close to the pylorus and often rather at the back of the duodenum, so that it is very awkwardly placed for suture. If is, however, quite possible to close it completely.

If the patient be left without operation, the diagnosis, as I have said, becomes still more obscure and my experience tells me that a perforated duodenal ulcer may be mistaken for pneumonia, for appendicitis, or for suppurative peritonitis from any other cause.

(B) NON-PERFORATING ULCER.

The second group of cases where there is a duodenal ulcer without perforation is even more interesting than the perforating variety which has just been considered. The diagnosis may be more difficult and the sequelæ demanding surgical treatment are no less urgent though they may be more remote. As may be gathered from what has been said of perforated ulcers, the signs of a duodenal ulcer may be absent or wholly inconspicuous and in such cases no diagnosis is possible. In some cases the patient complains of a continued pain in the abdomen which he can neither localise nor account for. He keeps his bed for a few days and then feeling better, goes about again saying that he has had a bad bilious attack. If he is nervous about himself or should the pain have been severe, he seeks medical advice, and is treated for gallstones, renal colic, or appendicitis. But the exact nature of his illness is probably not recognised unless he vomits a considerable quantity of blood, or has a sharp attack of melæna. Even then the case is thought to be one of gastric ulcer, unless an abdominal section is performed and the stomach is found to be healthy.

Hæmorrhage.—The hæmorrhage in some cases of duodenal ulcer is a characteristic symptom. It is sudden, painless, and very considerable in quantity. It seems to be due to erosion of the large arterial trunks which lie outside the duodenum—the superior pancreatico-duodenal artery being the most commonly affected, though the gastro-duodenal, the pyloric, the gastric and the pancreatica magna as well as the superior pancreatico-duodenal vein have been found ulcerated. The hæmorrhage may be so severe as to be fatal at once, more often the patient is blanched, or he may become faint without knowing the cause. This may happen on more than one occasion, and as the hæmorrhage is concealed, the cause is only recognised by the subsequent passage of large tarry motions. In other cases, the patient may have hæmatemesis instead of melæna, or both may be present.

Unless there is hæmorrhage, I do not know how a diagnosis can be established in the present state of our knowledge, but it is of no practical importance, for in the majority of cases the patient recovers from the attack unaided by art or if the bleeding be sufficient to need an exploration the surgeon performs a gastro-jejunostomy, whether the ulcer be situated in the stomach or in the duodenum. I have tried to recognise the condition by the character of the bleeding, by the time of the occurrence of pain after taking food, by the character of the material vomited and in many other ways, but always without success, for what is true and seems a valuable sign in one patient is worthless in another. I believe, therefore, that there is no pathognomonic sign of a non-perforating ulcer of the duodenum whilst the ulceration is in progress.

Constriction of the duodenum.—But if a non-perforating duodenal ulcer offers very few signs by which its presence may be detected, it may have sequelæ of the gravest character. The ulcer is usually single, and is situated in the first part of the duodenum, but like a gastric ulcer it is very chronic and may cause extensive inflammation in the submucous and muscular coats of the intestine. The inflammatory changes may extend to the serous coat and to the under surface of the liver. In process of time the ulcer heals and by the subsequent cicatrisation of the inflammatory products the duodenum is either narrowed, or it is constricted by the surrounding adhesions. The adhesions may not only affect the duodenum, but they may also involve the liver, the gall bladder, the pancreas, and such large blood vessels as the abdominal aorta, the hepatic artery and the portal vein. Such a patient presents himself as a man between 40 and 60, looking older than his years. Thin and haggard, he tells you that he is a martyr to indigestion, and that for months past he has suffered atrocious pain in his stomach which is relieved by vomiting. He has dieted himself in every possible manner, he has made all kinds of local applications to his stomach, he has visited all sorts of watering places, and he has gone in vain from one physician to another seeking a cure. Examination shows him to be a mere bag of bones, badly constipated with cold extremities and a listless dejected aspect. His abdomen is loose, the subcutaneous veins may be enlarged and there is visible peristalsis from left to right in the epigastric region. Palpation and percussion tell of a greatly dilated stomach and a tumour may sometimes be felt in the neighbourhood of the pylorus. For a moment you think of cancer of the pylorus or gall-bladder, and you question the patient a little more closely. He is sure that he has been suffering for years, for so long, in fact, that he hardly recollects the beginning of his trouble. A few well-directed enquiries may elicit that 25 or 30 years ago, when he was a young man, he once or twice brought up a large quantity of blood without serious pain or discomfort, or that he had an illness which no one seemed to know much about. He was treated for gallstones or for appendicitis or simply for "liver." The attack was abdominal, was painful, and kept him in bed, but the exact details have long since passed from his mind and for some years he was as healthy a man as ever.

This is a case of duodenal obstruction resulting from cicatrisation of an old ulcer, the irritation of which caused inflammatory thickening of the surrounding parts or of the duodenal walls. How many patients have been allowed to die of such a condition in the belief that they had malignant disease of the stomach no one can tell, but every pathological Museum contains several specimens of simple duodenal constriction.

The general symptoms of duodenal obstruction may be gathered from what has been already said. There is usually pain of the nature of dyspepsia felt an hour or two after taking food. The pain depends more upon the quality of food taken than upon the quantity. It is relieved by vomiting and the severity of the vomiting increases with the length of time the symptoms have lasted. It is usually copious and often painful. It is not a mere emptying of the stomach, for when the patient has vomited a large quantity, he will in an hour vomit as much again, although he has taken nothing in the interval. The attacks of vomiting are often worse at night than in the daytime. This seems to be particularly the case with business men, perhaps because they make a light breakfast, have but little lunch and make their chief meal in the evening. The attacks of vomiting, therefore, like the pain, bear a definite relation to the quantity, rather than to the quality of the food taken. The quantity of fluid vomited and the small amount of food digested and absorbed lead to very obstinate constipation. It is the relief of this symptom which is hailed with the greatest joy by a patient who has been cured by a gastro-jejunostomy, and the regularity of the bowels is one of the best proofs to the surgeon that his anastomosis is working successfully many months after the operation. The same loss of absorptive power leads to diminution in weight, to a harsh and dry skin, to a brittleness of the nails and to loss of the subcutaneous fat; in other words, the patient shows many of the signs of chronic starvation.

Diagnosis.—A systematic physical examination of the abdomen should be made in every case where there is reason to think that the patient is suffering from duodenal obstruction. The patient should lie flat on his back on a couch, with the knees bent and the shoulders slightly raised by a pillow. A good light is allowed to fall upon the abdomen and the surgeon should at first merely watch the abdominal movements without touching the patient. In thin people and in a case of marked duodenal obstruction the outline of the dilated stomach can often be seen with slow waves of peristalsis passing across the upper part of the abdominal wall from left to right. These waves in themselves are characteristic of some obstruction to the outflow of the gastric contents and the more healthy and active the person the more marked are the waves. The surgeon now places his hand flat upon the abdominal wall and his practised touch readily discovers the outlines of the enlarged stomach, even if there be no tumour or nodule perceptible in it. The position of the pylorus is often marked in these cases by a thickened nodule, which is easily mistaken for cancer, especially if, as in the case related above, the patient vomits a little blood from time to time. But the actual position of the pylorus varies greatly when the stomach is dilated and its exact position may not be detected at the first examination. The absence of a tumour does not preclude the diagnosis of duodenal constriction. Percussion is not of any great value in determining the size of the stomach, because a dilated stomach is often associated with a distended colon, and it is difficult to distinguish the note yielded by one from that of the other. Auscultation, too, is of no great service except to elicit the succussion splash. A dilated stomach can be easily distended by pumping in air, a proceeding which, though painless is unpleasant to the patient, or by the cruder method of administering separately the constituents of a Seidlitz powder. With these guides, there is really no excuse for overlooking a dilated stomach, or for being doubtful as to the existence of such a condition.

The teeth and gums should always be examined, as a matter of routine, to eliminate the possibility of the dyspeptic symptoms and constipation being due to chronic lead poisoning. It is better not to give a definite diagnosis until the bowels have been satisfactorily emptied by means of an enema, repeated if necessary, and it is wise to examine the abdomen more than once, and at different times after meals.

A test meal must always be given, and the presence or absence of free hydrochloric acid should be noted. The usual test meal consists of a thick slice of bread and butter with a breakfast cup of weak tea sweetened, but without milk. The meal is given at breakfast-time, and is withdrawn from the stomach an hour later by means of a stomach tube. The material withdrawn is filtered, and the residue is examined microscopically to see how far digestion has proceeded. The filtrate is tested with Günsberg's reagent for free hydrochloric acid. A few drops of the filtrate are mixed in a porcelain dish with an equal quantity of a solution consisting of phloroglucin 2 parts, vanillin 1 part, and absolute alcohol 30 parts. The mixture is evaporated to dryness at a gentle heat, and, if free hydrochloric acid is present, red crystals will form. As a broad rule, free hydrochloric acid is present in simple duodenal constriction: it is deficient or absent in cancer of the stomach.

Microscopically, too, the Oppler-Boas bacillus should be absent in cases of non-malignant constriction of the duodenum.

Treatment.—Palliative treatment in cases of duodenal constriction is chiefly directed to relieve the vomiting. This is done by rectal feeding and washing out the stomach, since the indications are clearly to keep the stomach empty and prevent putrefactive changes. The stomach is washed out with a warm solution of bicarbonate of soda (20 grains to the pint). A soft tube is passed into the stomach and its contents are evacuated, half a pint of the solution is then poured into the tube and is allowed to run out again, and this is repeated several times. In the early stages of duodenal constriction, the stomach need only be washed out every other day, and this is done most conveniently before breakfast; but in the later stages, when the vomiting is most distressing at night, the stomach should be washed out every evening just before the patient goes to bed, and about four hours after the last meal.

It is obvious that this treatment is only palliative, and it follows from what has been said already that patients who suffer from painful vomiting, with loss of flesh and constipation, should always be examined carefully to find out whether there is any dilatation of the stomach. When the stomach is dilated, and diet, combined with simple remedies, fails to bring about a cure, there should be no hesitation in recommending an exploratory incision with a view to the performance of a posterior gastro-jejunostomy by direct suture.

The operation should not be postponed until the patient has exhausted himself, because early operation is attended with comparatively little risk, and has a twofold advantage. If the patient is found to be suffering from cancer of the stomach, much more radical measures can be pursued in the early stages of the disease, than if delay has allowed the growth to infiltrate all the surrounding tissues. But even if the constriction proves to be due to malignant disease, and removal is impossible, gastro-enterostomy serves excellently as a temporary expedient. It has, too, the advantage over colotomy for the relief of an analogous condition in the rectum, that it leaves no open wound. The patient, therefore, is able to go about his ordinary work until the progress of the disease renders him incapable of further effort. If, on the other hand, the patient is suffering from duodenal constriction, which is not due to cancer, the surgeon can promise him a speedy relief from all the disagreeable symptoms, and a prolongation of his active life for many years in comfort.

CLINICAL RECORDS.

TREATMENT IN TWO CASES OF RECURRENT AND INOPERABLE CANCER.

By J. A. SHAW-MACKENZIE, M.D., Lond.

The following brief notes of one of my recent cases, are, I think, worthy of record.

1. Mrs. —, Recurrent Carcinoma of the Breast.—In February, 1904, a well-known surgeon removed the right breast. The patient made an excellent recovery, but in the following year there was recurrence of the disease, and in November, 1905, a second operation was performed. Recovery from this was extremely slow, and the patient was under surgical care until the middle of last year, when a well-known physician was consulted for increasing dyspnœa.

On June 6th, 1906, the patient came up from the country to see me. She was suffering from extreme breathlessness on exertion. Bronchial rales were present at both apices; the left breast was involved; there were several recurrent nodules on the right side of the chest, and the supraclavicular and axillary glands were enlarged on the left side. It was ascertained that there was a diabetic history on the father's side, and the patient herself had distaste for sugar. She had the strongest objection to any further operation, an objection which was also shared by her husband. Her physician kindly wrote to me that "there is much more trouble than a month ago when she was last here, and I think her breathing troubles are probably due to enlargement within the thorax. I agree with you that Mrs. —— is not a favourable case, but one feels that anything is worthy of trial." The internal administration of pancreatic and intestinal gland preparations (Allen and Hanbury's), together with purified ox gall were prescibed and excess of sugar recommended to be added to the diet. On June 26th she came to see me again. All pain which on the previous occasion was complained of had ceased, while the appetite and general condition had improved. She remained now in town for further treatment and hypodermic injections of soap solution (the method of Mr. J. H. Webb, of Melbourne), together with hypodermic injections of chian turpentine on alternate days were commenced. In three weeks' time the patient appeared to be distinctly better in every way, and her physician, after seeing her again, wrote to me: "The general condition is wonderfully better; in fact, all her subjective symptoms are in abeyance. The induration in the left breast seems to be rather less definite than when I last saw her, and they are certainly no larger. I hope things will go on as they have begun. It is certainly encouraging." She now returned to the country, and the treatment was kindly continued by her medical man. During August and September he wrote that she appeared to be holding her own. The treatment remained the same with the exception that in August iodipin was added to the chian turpentine injections, on the recommendation of Dr. John Shaw, who at that time was acting for me in my absence from town, and in September trypsin injections were alternated with the soap injections. In November, however, she was reported to have relapsed with a return of dyspnœa and cough, loss of of appetite and bad nights. The opsonic index of the blood to *M. neoformans*, which on several previous occasions proved to be normal, was now found by Dr. Aylmer May, on examination in series, to be irregular and characterised by very low and high phases. In spite of the unfavourable aspect of affairs, having learned from various examinations of the opsonic index, undertaken for me by Dr. May, in other cases that the dosage and strength of trypsin could be apparently increased, it was determined to push treatment, and the injections of trypsin and of chian turpentine were recommended to be given daily, while the pancreatic and intestinal gland preparations, which had been omitted for a time, were again resumed. On December 13th I visited the patient, who was able to be up and about, but very breathless on the least exertion. No physical signs in the chest were discoverable, and no increase in the external manifestations. There was no tendency to breaking down of the tissues, and the enlargement of the left breast appeared to be in a quiescent and atrophic condition, while the glandular enlargements were much less evident The same treatment was continued, and on December 30th she was reported to be again greatly improved. On February 17th, 1907, her medical man wrote to me: "The condition appears more or less stationary, she has, if anything, lost flesh, but the disease does not appear to have made way; the most marked symptom is dyspnœa on exertion." Towards the end of this month severe indigestion was complained of; the appetite fell away almost entirely, though when I saw her on the 28th there was no apparent increase of the disease or abdominal metastasis. It was agreed to continue the daily injections, which in themselves caused no pain or inconvenience, and to omit the pancreatic and intestinal gland preparations by the mouth. A bismuth mixture was suggested by her medical man, and almost immediately he was able to report improvement in the digestive and dyspnœal conditions. The opsonic index about this time was found by Dr. J. C. Matthews on two consecutive occasions to be above normal. The patient's husband—himself a son and grandson of members of the medical profession—now (May 1st) writes, with full permission to publish notes of this case: "For the past two months the appetite has become extremely good; she has slept well and her spirits are excellent. When weighed just over a month ago she had gone down to 7 stone 13 lbs. (a loss of nearly 2 stone); the weight remained stationary for a fortnight, but, last week—a further fortnight—a gain of nearly 3 lbs. was recorded, and, again now (May 10th) another 3 lbs. For months it was quite impossible for my wife to walk at all without her breathing becoming most distressing. For the last few weeks, however, this has all changed, she is now able to go up and down stairs quite freely, her breathing has become normal, and as recently as a fortnight ago—to show the improvement in her general health—she was able to take a drive of some sixteen miles, returning quite unfatigued. The lumps in the neck and on the right side have now practically all disappeared and the breast is becoming quite flexible. One remarkable feature is that during the time my wife has been under the treatment, she has been quite free from pain."

Note.—The diagnosis in this case cannot be questioned any more than the advanced and advancing state of disease eleven months ago. The obvious improvement and encouraging progress in this case must as I think, be attributed to treatment, coupled with—I cannot refrain from noting—the patience and determination of the patient herself.

The following case also will be read with interest :—

II. Mrs. —, Recurrent Carcinoma of Breast.—The right breast had been removed in September, 1904; further operation for recurrence in March, 1905; further removal of axillary glands in December, 1905, with tedious recovery and bad prognosis. The patient came to see me on March 6th, 1906; it was ascertained that she had avoided sugar for ten years; the weight of the patient was 9 stone 2¼lbs. She was pallid and feeble, but there was no obvious disease. With the object, if possible, of preventing recurrence, pancreatic and intestinal gland preparations (Allen and Hanbury's) were prescribed to be taken by the mouth and sugar recommended to be added to a carbohydrate and fatty diet. On July 17th the weight had increased to 9 stone 11 lbs. On this date some fullness was noted in the right supraclavicular region. On November 26th her weight was 10 stone 11 lbs., which she informed me was more than she recollected having weighed in her life; she looked well and stated that some glands had been removed in the autumn, followed by a quick and satisfactory recovery. Mr. P. W. L. Camps, of Teddington, who performed the operation, was good enough to write to me expressing the interest he had taken in the previous treatment, and the fact of the great improvement in her general condition which had taken place since Christmas, 1905, which he thought she owed to my treatment. He had removed four tiny lumps in the supraclavicular region, one of which proved, on microscopical examination, to be normal lymphoid tissue, the others carcinomatous, but quite limited at their borders by fibrous tissue, which fact appeared to show the localisation of the disease which was taking place. In a subsequent letter, December 18th, it is right to note that Mr. Camps wrote, "we have treated other cases here with trypsin and have been rather disappointed, but the case of Mrs. —— I have looked upon as the most interesting one, pathologically, which I have come across." May, 1907. In reply to me for any report Mr. Camps kindly writes that he has not seen the patient since but that he heard from her about a month ago briefly stating that she was pretty well.

OPERATING THEATRES.

NORTH WEST LONDON HOSPITAL.

Plastic Elongation of Tendons.—Mr. Jackson Clarke operated on a woman æt. 25, who had severe talipes equinus on both sides. She came to hospital seeking relief from a painful spot where tendon elongation had been done some two years previously on the right side. The condition of talipes equinus having recurred, the adherent scar over the newly-formed tendon had broken down partly owing to friction and partly to the working out of a stitch. The practical lesson to be learnt from the history in this case, Mr. Clarke said, was never to make the skin incision immediately over the tendon, and also to re-unite the sheath of the tendon over the sutured ends before closing the skin wound. These points he proceeded to illustrate in his operation, on the left foot where no operation had previously been done; the condition of equinus was a severe one, the foot being almost in a line with the leg. The patient being turned on the right side, an incision was made beginning near the middle line about five inches above the heel, and then passing downwards with an outward convexity to the outer border of the tendo achillis, close above the heel. This flap of skin and fat was dissected up and turned inwards to expose; the prominence of the tendo achillis in the middle line the external saphena vein was exposed in dissecting up this flap, and divided at the upper end. The sheath of the tendo achillis was now divided in the middle line to the whole extent of the exposed part, each half of the sheath being drawn apart in order to separate it from the side of the tendon, where it was attached, and it was pointed out that this synovial sheath did not extend to the front of the tendon from which the cellulo-fatty tissue was next separated by blunt dissection. The tendon was then divided down its middle for about three inches. At the upper end of this incision in the tendon a cut was made outwards and at its lower extremity another cut was made inwards, thus completing the Z-shaped section of the tendon. The position of the foot was now corrected, which brought the extremities of the tendon close to one another, where they were secured with two fine silk stitches. The delicate tendon sheath was now sutured with five fine silk points. The skin flap was then secured and the limb put up on a posterior rectangular splint which was so padded that there was no pressure over the site of operation. The other (right) foot was also in a state of rigid equinus and presented a scar which had broken down into granulation tissue in its middle point. This scar resulted evidently from an incision made two years previously in doing a tendon elongation. The scar was still closely adherent to the subjacent tendon which felt unusually hard. In this case Mr. Clarke made an incision similar to that already described on the left side and dissected up a flap of skin including the scar. The subjacent tendon was divided obliquely and a silk stitch which remained from the previous operation was removed; no sutures were used, but a gap was left between the ends of the tendon before the skin flap was replaced in position and the limb was put up with an anterior malleable metal splint. Mr. Clarke said that the condition presented on the right side showed how important it was to use a sound operative technique, even in a simple operation like the plastic elongation of a tendon. When the incision is made immediately over the tendon the resulting scar lies on a hard prominent structure, and chafing and excoriation are almost inevitable, and further when the synovial sheath which nature has placed on the posterior aspect of the tendo achillis, is not restored in the course of the operation the tendon becomes adherent to the skin and its freedom of action is impaired, whereas when the operation is done in the manner he had employed on the left side, the lengthened tendon works as freely and is as strong as the normal. He pointed out that this operation when skilfully performed was preferable to a simple tenotomy, the latter in many cases resulting in an excessive elongation which often produced talipes calcaneus, a deformity worse than the talipes equinus, for which the operation was indicated.

TRANSACTIONS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

Meeting Held Friday, May 10th, 1907.

The President, Mr. H. H. Clutton, in the Chair.

Mr. James Sherren read a paper entitled :

"Gastro-enterostomy for Chronic Gastric Ulcer. Healing of Ulcer Verified at Post-mortem Examination Twenty-Eight Months Later."

The patient, a man æt. 46, was admitted to the Poplar Hospital in October, 1904. He had had gastric symptoms for six years, and for nine months had been in bed with severe pain, and which prevented him from taking solid food. An operation was performed and a large ulcer was found on the lesser curvature. Posterior gastro-enterostomy, being impossible on account of adhesions, the anterior operation was done, with no loop. Great improvement ensued, but twenty-two months later melancholia developed and the patient cut his throat. At the autopsy the stomach was found to be only slightly adherent to the pancreas. The gastro-enterostomy opening admitted two fingers, and the pylorus was also patent. The ulcer, examined microscopically, had healed completely. Mr. Sherren commented on the good results obtained through gastro-enterostomy even when the ulcer was distant from the pylorus, so that excision was not the operation of choice even in such cases.

The President asked whether Mayo's method of fixing the jejunum so as to make it lie from left to right had been adopted. He had used it as a routine measure for the past eighteen months.

Mr. Sherren replied in the negative. He had tried Mayo's method in later cases but had given it up.

Dr. Herbert French and Dr. G. Louisson read a paper entitled :

"ON THE EXTENT TO WHICH WIDAL'S REACTION PERSISTS AFTER RECOVERY FROM TYPHOID FEVER."

The authors had traced 135 patients who had, whilst in Guy's Hospital with typhoid fever, given Widal's Reaction, the standard being clumping within half an hour in a dilution of 1 in 200. The test was repeated in these patients, at periods after the illness, varying from two months to ten years. They concluded : (1) In 7.5 per cent. of the cases a complete reaction was obtained, in 22.5 per cent. an incomplete one, and in 70 per cent. no reaction. (2) The interval that had elapsed after the illness made comparatively little difference. It would almost seem as if the cases that persisted at all, persisted perhaps indefinitely ; several cases lasted eight years. (3) A complete reaction was present in 11 per cent. of the men and in none of the women. (4) Suppurative complications made it only slightly more probable that the agglutinative power would persist. (5) Age bore no relation to the likelihood of persistence.

The President remarked that he had found the bacilli in bone complications three years after the fever.

Dr. W. P. Herringham discussed the question of second attacks in specific fevers. This bore no relation to the severity of the first attack, or to age. In measles women were more likely to suffer from a second attack than men, though the reverse held with typhoid.

Dr. French, in reply, said he had not examined the cases for bacilluria, &c., and it was possible that the persistence of bacilli might be correlated with the persistence of agglutinative power.

Dr. Leonard Guthrie and Dr. W. D'Este Emery read a paper on

"PRECOCIOUS OBESITY AND HIRSUTIES, WITH HYPERNEPHROMA."

The patient, a boy, æt. 4¾ years, was 36 inches high, and weighed over four stone. There was a large general growth of hair, but the genital organs were not developed. There was marked general obesity, especially pronounced in the cheeks and mammæ. After death from pulmonary tuberculosis a hypernephroma was found on the left side ; microscopically it consisted chiefly in necrobiotic cortical adrenal tissue ; many giant cells were present. It was probably a carcinoma, although there was no infiltration or metastasis.

Another case was also described in a girl, æt. 3½ years, who measured 30 inches high and weighed 37 pounds. In the previous three months she had grown an inch and gained six pounds. She measured 26 inches round the abdomen and 13 inches round the thigh. There was general obesity with pendulous mammæ. She had the appearance of a woman æt. 50. The cheeks were bloated and blotchy. There were lineæ gravidarum on the thighs. Hair grew on the pelvis at the age of three, but the sexual organs were not developed. At the autopsy no growth was found, but the adrenals were not microscoped. In both cases the pulse was very intermittent, and the intelligence good. The cases collected by Bulloch and Sequira were criticised, and stress was laid on the general obesity of the majority of them ; nine of the cases were in girls, and two in boys. In twelve cases the growth was on the left side, in two on the right.

Mr. Hughlett described a similar case in a boy, æt. 4. The overgrowth of hair had begun at the age of 2. He was 3ft. 7½in. high and weighed 3st. 12lbs. He was mentally bright. His muscular development was remarkable. The thighs measured 16in. around, and the chest 27in. His voice broke at the age of 4. The femoral epiphyses were united.

Mr. Raymond Johnson referred to a case he had seen of a boy, æt. 14, with enormous muscular development and hirsuties. The boy had had to shave daily since the age of 10. A large perithelioma of the advenal was present and slowly proved fatal.

Mr. John Malcolm spoke of a woman, æt. 50, who had had a large adrenal tumour removed by operation. An overgrowth of hair had been developing for years and she had had to shave daily.

Dr. Parkes Weber divided the cases into two groups. (1) Those with great muscular development ; (2) those with precocious obesity. He separated the latter cases, with a bloated stretched skin, from cases of "excessive obesity." There was a case on record in a boy, in whom such symptoms, including a beard, had disappeared after removal of a testicular tumour. Might an advenal tumour grow in connection with the testicle ?

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Meeting held Wednesday May 1st, 1907.

Dr. Geo. Hunter, Vice-President, in the Chair.

Dr. W. T. Ritchie read a paper on the

DIFFERENTATION OF THE VARIETIES OF EXTRA-SYSTOLE.

After a reference to the researches of Tawara and of Keith and Flack upon the muscular connections between the superior vena cava, the auricles and the ventricles, it was pointed out that the extra-systole was the evidence of the heart's response to a heterotopic stimulus. The general characters of the pulse in the extra-systolic irregularity were described, and it was shown that, by an analysis of graphic records demonstrating the sequence in which the auricles and the ventricles contract during an extra-systole and the time interval between their contractions on that occasion, the initial point of heterotopic stimulation might be deduced. The distinctive features of the varieties of extra-systole were then described. According to the initial point of heterotopic stimulation, three main varieties of extra-systole—the auricular, the auriculo-ventricular, and the ventricular—may be recognised. When an auriculo-ventricular extra-systole occurs, the auricular beat may be premature as well as the ventricular, and the former may then precede, coincide with, or follow the latter, according to the portion of the a–v bundle first stimulated. It was suggested that the auricular beat precedes the ventricular in the case of supranodal and nodal auriculo-ventricular extra-systoles ; when the mid-point, probably the main stem, of the bundle is the initial point of stimulation, the auricular and ventricular beats coincide ; in other cases of infra-nodal auriculo-ventricular extra-systole, in which the ventricular beat preceded the auricular, the heterotopic stimulus probably proceeded from the ventricular ramifications of the a–v bundle. In the latter instance, the auricular extra-systolic wave may be premature, or the auricular rhythm may be unaltered. Cases of continued cardiac irregularity resulting from auriculo-ventricular extra-systoles in series were recorded, and in conclusion the three forms of ventricular extra-systole—the retrograde extra-systole, the interpolated extra-systole, and that with a period equal to the succeeding physiological systole, as observed in cases of heart-block—were described.

The paper was fully illustrated with slides, showing cardiac and other tracings from numerous cases of extra-systole.

Dr. **Geo. Hunter** and Dr. **G. A. Gilson** discussed the paper.

Dr. **Claude B. Ker** read a paper on

INTUBATION OF THE LARYNX IN LARYNGEAL DIPHTHERIA.

A full abstract of which will be found on page 531.

In the discussion which followed

Mr. **Cathcart** spoke of the difficulty of learning to intubate, and asked whether practise on the cadavor was of enough value to be worth while giving to students He thought the hint about nasal feeding a very valuable one. Mr. Wallace spoke of the risk of the patient dying on the table during tracheotomy; he asked whether intubation was safer in that respect. Dr. Macmillan said that in Paris, Varrot, who once strongly opposed the practice, now performed intubation as the operation of election.

Dr. **Ker** said that undoubtedly the procedure was difficult at first, and unfortunately practise on the cadavor was no use. He had only had one death—from heart failure—at the moment of intubation.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

Meeting held Friday, May 3rd, 1907.

Dr. T. R. **Whipham** in the Chair.

Amongst the cases shown were the following :—

Dr. C. O. **Hawthorne** showed a boy, æt. 14, with

DEXIOCARDIA AND VALVULAR DISEASE.

There was a systolic murmur heard at the apex on the right side and conducted round the right side of the chest. A skiagram could not be obtained, but there was no doubt complete transposition of the heart, but not of the other viscera. Dr. Hawthorne also showed a child with symmetrical congenital deformity of the ears, with sufficient hearing.

Mr. **Hugh Lett** showed a baby, æt. 7 months, with "Multiple Fractures of the Bones," noticed at birth; skiagrams showed old fractures and thickening due to callus. There was hydrocephalus and some evidence of rickets. The family history was good, but the mother had been in delicate health during pregnancy, and had two bad falls during the seventh month.

Dr. F. W. **Higgs** showed a case of "Monoplegia," presumably due to embolism of a cortical artery, in a girl æt. 8, who had chorea and rheumatism a year ago, and developed mitral regurgitation. Five weeks ago paralysis of the left upper limb occurred during sleep, there was no other paralysis. Partial recovery had occurred in the following order : flexors of fingers, of wrists, supraspinatus, flexors of elbow, extensors of fingers. He also showed a boy, æt. 3, who, while recovering from whooping-cough about two years ago, developed pain and swelling in certain joints. The lesions persisted in a subacute form, and at present there was periarthritis of the joints of the wrists, ankles, knees and cervical vertebræ. Spleen and glands were not enlarged. The disease was evidently toxæmic.

Mr. **Pernet** showed a case of "Erythema Iris."

Dr. **Porter Parkinson** showed a case of "Cerebral Tumour after Craniotomy." The optic neuritis, previously very intense, had disappeared, and the headache, vomiting and convulsions were completely relieved, while the paralysis had improved in the face and arm. The tumour was probably a subcortical glioma.

Dr. D. C. L. **Fitzwilliams** showed a boy, æt. 10, with "Multiple Exostoses" on the long bones, ribs, scapulæ and clavicles. The child was the youngest of a family of seven, the mother and all the children showed similar growths, but had suffered no inconvenience, and they had not increased after the first few years of life.

Dr. W. **Ewart** showed a boy, æt. 6, suffering from old standing "Spinal Caries," with much weakness of the legs and back; he had received much benefit from extension on a "sliding mattress" and by exercises on the "all-fours exerciser."

Dr. T. R. **Whipham** showed a case of "Morbus Cordis," in which there had been 7,800,000 red blood corpuscles. The patient, a girl, æt. 11, was subject to epistaxis. The heart was enlarged and there was a thrill at the apex and the aortic base, and presystolic and systolic murmurs at the apex, and a rough aortic systolic murmur. The second sound was absent except at the pulmonary base, where it could be faintly heard. There was no cyanosis or clubbing. There was probably aortic stenosis and congenital narrowing of the aorta.

Mr. **Lockhart Mummery** showed a boy, æt. 3 months, with "Erb's Paralysis of the Left Arm," due to a difficult labour. Apparently the posterior cords of the brachial plexus had been ruptured, causing paralysis and electrical changes of the flexor and extensor muscles except the flexor sublimis digitorum. There were some adhesions in the shoulder joint.

The cases were discussed by Drs. Hawthorne, Higgs, Chapman, Clutterbuck, Porter Parkinson, and by Messrs Mummery, Russell Howard, Lett, Jaffrey, etc.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Meeting held Friday, May 3rd, 1907.

The President, Dr. **Leonard Mark**, in the Chair.

A paper was read by Mr. **R. Lake**, on some results of

NASAL OBSTRUCTION.

Mr. **Lake** referred particularly to conditions connected with the special regions of the naso-pharynx, the pharynx, larynx and ear, and also with the general system, the chest, the general development and the intelligence. The reader also insisted on the differences existing between the results of structural obstruction of the nose, commencing in early life, and that arising in later or adult life.

The paper was discussed by the President, Mr. Garry Simpson, Dr. J. B. Ball and others.

Mr. **George Pernet** then read an exhaustive and valuable account of

HÆMORRHAGIC RASHES,

dealing with the pathology of these manifestations, the conditions under which they occur, the differentia in their diagnosis, and with the methods of treatment to be employed. The paper contained many important references to the literature of the subject.

A discussion followed in which the President, Dr. Phineas Abraham, Dr. Rice Oxley, Dr. Richard Lloyd, and others participated.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, May 12th, 1907.

Treatment of General Paralysis.

If the intensive mercurial treatment prolonged during some years has a chance to improve locomotor ataxy (Babinski gives an injection of one grain of calomel every eight days) it does not act with so much impunity in the treatment of general paralysis or softening of the brain where numerous complications have been observed.

Prof. Raymond declares mercury useless and dangerous in general paralysis, and the majority of neurologists share the same opinion. For these the disease, under the influence of the specific treatment, may become acute and rapidly fatal.

This opinion, however, has been contradicted by a rising neurologist, Dr. Roux, of St. Etienne, who considers that the calomel treatment has been wrongly accused. According to him, the complications of meningo-encephalitis are chiefly due to other influences: drinking to excess, infectious maladies or some other toxic influence.

All that an injection of calomel can do is provoke a febrile condition with pneumonia or gastric disturbance, but they are not peculiar to general paralysis as they can be observed in ataxy and syphilis of the brain.

M. Roux, who has treated hundreds of cases of general paralysis, and practised thousands of injections of calomel, has observed febrile complications chiefly in those patients where the apex of the lungs were slightly diseased. To avoid accidents of this nature he advises that the treatment should not be undertaken in the course of an acute paroxysm or during an acute intercurrent affection and in all cases to determine the susceptibility of the patient by very small doses. The urine should in all cases be examined for some abnormal condition.

If the result is negative, small doses (½ gr. of calomel) might be injected and if no febrile action or gastric disturbance are observed as a consequence of the injections the next injection, eight days afterwards, might be given a little stronger. If the treatment is well tolerated, the injections are repeated and the dose progressively increased to one grain, or one grain and a half of calomel weekly.

By these precautions all accidents are avoided and an improvement takes place in the state of the patient, on the condition, however, that the malady has not reached the period of dementia, for which nothing can be done.

At the very outset, the development of the malady is temporarily arrested; as to the hybrid forms, where the diagnosis hesitates between cerebral syphilis and general paralysis, where the patients present acute cephalgia, paralysis, delirium, and a weakening of all the faculties, a cure is the rule. Consequently no injections of calomel should be given in the acute form, during intercurrent toxic affections or where dementia has set in. In all others commence with small doses of calomel, and follow up the results obtained and cease altogether in case of complications.

Camphor and Ether employed in Large Doses.

Injections of camphor and oil are commonly employed in collapse as a good stimulant equal, if not superior, to caffein.

According to a confrère, the doses employed are much too weak and the results would be considerably better if the camphor were injected more freely.

For a long time he has been in the habit of injecting very large doses, 2, 3, or 5 drachms of a solution of 25 per cent. in the space of one or two hours, and he never met with any symptoms of poisoning, the effect, on the contrary, was such as to render unnecessary the administration of musk or caffein.

After the three days which followed this first injection of camphor, doses of camphorated oil are given less and less frequently, according as the condition of the patient improves. Finally the injections are replaced by the administration of camphor by the mouth.

The injections are made in the hypogastric region and are but slightly painful.

In all acute infectious maladies, as soon as the heart sounds become dull and the pulse irregular, the camphor should be injected. In cardiac and renal affections the action of digitalis and diuretics is increased by camphor given by the mouth, 4 grs. three or four times a day.

As to the injections of ether, they are seldom indicated as the camphor is sufficient But sometimes the state of the patient necessitates the employment of both. In such cases, large doses of ether should be injected (1 drachm) every hour or two, alternating with injections of camphor. The results are remarkable especially in alcoholic patients.

Abortive Treatment of Suppuration.

Every practitioner knows how to use hot water for a localised infection in some point of the organism.

Its employment has become general since Prof. Legars read a paper on the subject at the Surgical Congress of 1898. When a patient has an infected wound, or suffers from lymphangitis the result of a prick, for instance, he is recommended to place the limb in a large warm bath several times a day.

The results are very satisfactory, and superior to antiseptic dressings. Where bathing is impossible, hot moist compresses act equally well.

However, there exists another means of preventing suppuration still more active, and employed by Prof. Tillaux. After the parts are well rubbed with soap and the nail brush, a compress of several folds of gauze, moistened with ether is placed over the seat of inflammation, and covered with oil silk, to prevent too-rapid evaporation and fixed by a bandage. The patient is recommended to raise a corner of the dressing every hour to pour in a sufficient quantity of ether to moisten the compress. The treatment should be continued several days. The results are constant; the suppuration retrogrades, and a cure is certain to occur in less than a week.

GERMANY.

Berlin, May 12th, 1907.

At the Verein für Innere Medizin, Hr. Michaelis spoke on

Further Experimental Investigations with Cancer Inoculation.

He said that by a preliminary treatment of mice with normal liver tissue he had succeeded in setting up some degree of immunity, although he had failed in all other ways. Treatment with moderately indifferent material, such as cows' milk set up no trace of immunity whatever, not even when living cancer material from rats was made use of. His differences from Ehrlich's results he explained to be from difference of material.

Hr. Schöne had experimented in Ehrlich's Institute with hæmorrhagic spontaneous tumours and had achieved immunization in 50 to 80 per cent. of the cases which, after repetition of the immunization became almost absolute. Immunity was also brought about with tissue cells; this was probably different from the immunity from spontaneous tumours, as the rapidly growing tumour was opposed to any immunization, it was probably correct, therefore, to extirpate the tumour first.

Hr. Westenhoeffer agreed with Schöne's views. He regarded Michaelis' communication with a certain scepticism, as they bore their own contradiction, as a recurrence was a younger tumour that was attacked in its growth. So much seemed to be shown by Michaelis' experiments that nothing specific was contained in the tumour.

Hr. Lewin said that in rat tumours which grew rapidly and set up metastases abdominal recurrences were seen eight days after extirpation and, shortly afterwards metastases.

Hr. Sticker said that when a tumour was caused in a dog, a new tumour could not be set up. Several primary tumours might originate, but new tumours could not be set up by a new inoculation. That was the tumours might be "multilocular," but not "multitemporæ." A new tumour could only be set up when the first was removed. He assumed three zones—firstly, that of the tumour itself, the central zone; secondly, that lying in the periphery of the tumour, and governed by it, the tumour zone: and thirdly, the adjoining immune zone. If the tumour extended its region the immune zone became smaller and smaller, and finally disappeared. He related a case of retrograde development of carcinomata on the lips that could only be explained by destruction of the immune zone.

Hr. Lewin was firm in declaring that with rats with carcinomatous tumour in various places, inoculation from other animals had been successful. These were facts which he could not bring into unison with the conclusions of the last speaker.

The Surgery of the Heart.

In opening the discussion on Hr. Rehn's paper, Hr. Sauerbruch Greefswald remarked that the course run by wound of the heart was influenced by pneumo thorax. This arrested the hæmorrhage which at first was a favourable result, but the pressure at the same time seriously hindered the heart in its action, and fatally so. Then when the pneumothorax existed a long time it led to secondary infection. One advantage of the collapse set up by penumothorax was that operation could be carried out much more easily. What had been said of temporary compression of the heart without any definite injury he could confirm.

Hr. Glück, Berlin, mentioned a case of gunshot wound of the heart with hæmatopericardium that recovered, and further a case of total resection of the sternum, clearing out the anterior mediastrium of caseous masses and resection of the tuberculous anterior wall of the pericardium. The patient died of pulmonary phthisis a year and a half later. He recommended as the spot for making the opening the 4th or 5th intercostal space in the mammary line, or for pulmonary puncture 1 to 2 finger-breadths outside the line. For pericardiotomy the 5th rib should be resected outwards from the line. In this way there was some certainty of not wounding the pleura. He related two successful cases.

Hr. Thiermann, Jena, showed a labourer, who in lifting a heavy weight had forced a large sewing needle that was stuck in his coat into his chest, injuring both the right ventricle and right auricle; a suture was inserted, and the patient recovered.

Hr. Gœbell, Kiel, said that pneumothorax could be overcome without the aid of a special pneumatic chamber. Like Quénu, he had drawn off the air by Potain's suction apparatus. Injury could easily be inflicted on the cardiac muscle by suture. For suture he advised three silk ones made as aseptic as possible, the suture not to be too deeply placed.

Hr. Küttner Marburg, showed a patient on whom a year and a half before he had successfully performed cardiolysis for adherent pericardium.

Hr. Heller, Stettin, said that it was often not possible to make a diagnosis as to the injury. But even when the diagnosis was doubtful, the thorax should be opened so as to make quite certain, and to operate if necessary. It was the only means of saving life. Sometimes only a very small incision was required. Large flaps were objectionable.

Hr. Kümmell, Hamburg, said that even after cessation of the heart beat, the beat could be restored by immediate massage of the heart after opening the thorax.

Hr. Franke, Brunswick, said that, as the movement of the heart was often arrested by pressure of blood poured out into the pericardium, the surgeon first called to the case could often help by puncturing the pericardium, and aspirating the hæmorrhagic contents.

Hr. Reidal, Jena, mentioned a case of massage of the heart. A medical man had to be operated on for ulcer of the stomach. When the speaker had opened the abdomen, respiration and cardiac movement suddenly ceased; the patient lay dead on the operating table. All the various methods of restoring life failed. After at least half an hour had been spent in this way he began to massage the heart from the open abdomen. After about ten minutes it began to beat again, and the patient was carried from the table to his bed alive. He never came to, however, but died some hours later of collapse.

In reply, Rehn said that Barth agreed with him as to the value of large bony flaps. He was acquainted with the value of massage of the heart and had seen cases saved by it.

AUSTRIA.

Vienna, May 12th 1907.

LUPUS PERNIO.

SALOMON showed a young woman to the Gesellschaft suffering from lupus erythematosus of a chronic character on the hands. She had also extensive cicatrices from scrofulous glands in the neck with a scurvy-lupus exfoliation, but the marked reddening of the hands was the most interesting point in this case. Hutchinson applied the term "chilblain lupus" or lupus pernio to this form which was sometimes recognised as a combination of lupus erythematosus and lupus vulgaris, if such a combination be possible. It has long remained a disputed question whether these two diseases produce the clinical appearances described under the term lupus pernio or whether the latter is a distinct disease, having a totally distinct cause.

Lang said the combination of typical lupus erythematosus with lupus vulgaris was a very rare coincidence in the same individual at the same time. In all his experience, he could recall to memory only one case where the two diseases were present. The patient suffered from lupus erythematosus for years and finally took on the lupus vulgaris in a typical form along with the former which was subsequently proved histologically.

MULTIPLE CARTILAGINOUS EXOSTOSIS.

Necker exhibited a patient with a large osseous tumour which had commenced to form two years ago about the seventh cervical and first dorsal vertebræ. Tumour was about the size of a man's fist, and pressed on the cervico-brachial plexus, producing atrophy of the muscles of the right hand without any loss of sensibility with ptosis and pupillary dilation of the right side. The radiographic examination showed atrophy of the bones in the right arm. On the posterior surface of the tibia there was another localised exostosis of a sarcomatous nature leading also to degeneration. A particular feature in this case was the hereditary tendency, as a daughter, æt. 22, was afflicted with the same kind of swellings here and there of a cartilaginous character.

PHOSPHORIC NECROSIS.

Eiselberg presented a case of phosphoric poisoning, where the whole of the upper jaw was necrosed and broken. By the application of bandages to the neck the congestion had loosened the large sequestra which he now purposed to remove by operation.

On the etiology of this destruction of tissue and bone, Latyko affirmed that it was not the local application of the phosphorus that produced the necrosis, but the presence of a surplus in the body. In support of this assertion he related the case of osteo-malacia which came under his charge to which he gave full doses of phosphorus for years with the result that caries of the teeth led to periostitis and destruction of the upper jaw, which ultimately produced septic poisoning and death. This he thought threw a different light on the action of phosphorus as he had always understood that it was the direct action such as the fumes that caused the necrosis, but he now was persuaded that it was the indirect action of the metalloid that produced the destruction of tissue and bones. It was in reality a chronic state of phosphorus poisoning.

SCOLIOSIS.

Frisch next brought forward a case where scoliosis commenced a year ago without any real cause in the young man's history, who was now eighteen years of age and a locksmith by trade. The usual causes are traumatism, growths, caries, and congenital weakness. The first, second, and third were negatived by the Röntgen photographs, which only leaves the congenital in this case. It appears from closer observation that the first lumbar vertebra is quite absorbed, leaving only a rudimentary trace. That the scoliosis only appeared a year ago is not incompatible with a congenital origin, as many other examples of spinal defects have not declared themselves till as many years had passed. To show the difference in an accident he presented a man who, when carrying a heavy load, fell and was afflicted with paralysis, but after nine weeks recovered. The Röntgen rays showed luxation of one of the lumbar vertebræ nearly its own width towards the left.

Engelmann was of opinion that the case was the result of a fall and not congenital.

THE spotted fever epidemic is on the increase in Belfast. At the last meeting of the health authority it was reported that the total cases up to the present were 398. During the week twenty-five deaths occurred, bringing the total deaths up to 279. Six new cases were reported.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

The late Dr. Hamilton Ramsay.—A figure of some note in contemporary Scottish history has been removed through the death of Dr. Robert Hamilton Ramsay, which took place at Torquay on May 4th. He was born in Edinburgh in 1824, the son of Mr. Peter Ramsay, Banker, and the Hon. Susan Mary Hamilton, daughter of the seventh Earl of Belhaven and Stenton. Dr. Ramsay was, while scarcely more than a schoolboy, attracted to the study of medicine by charitably attending cases of cholera during an epidemic in a mining district, and he entered at the universities of Edinburgh and Glasgow to obtain a degree. He spent several years as house surgeon in the Royal Infirmaries of the two towns, in the latter of which he served under Lord Lister. As the oldest of the many house surgeons whom Lord Lister had trained, Dr. Ramsay handed to his master an album containing an address from his " grateful and affectionate pupils " on the occasion of his elevation to the peerage in 1897. Dr. Hamilton Ramsay was for nearly half a century a prominent figure in the ecclesiastical world of Scotland, or at least, in that section of it which adheres to the Church, " as by law established." In his youth he was constantly at Holyrood in attendance on his uncle, the Lord High Commissioner of the period, and from 1853 to 1892 he discharged the duties of purse bearer to a series of Lord High Commissioners. On his retirement past and present members of the assembly gave him a loving cup, an address, and a purse of gold. Dr. Hamilton Ramsay was an ardent horticulturist, and his garden at Torquay was one of the finest sub-tropical gardens in existence.

Aberdeen Royal Infirmary.—Lord Mount Stephen, who, in 1902, endowed the Infirmary to the extent of £1,000 a year, has generously handed a further benefaction of £10,000 to the institution.

BELFAST.

Public Health.—During last week there were 30 cases of cerebro-spinal meningitis notified, bringing the total up to 398. There were 25 deaths, making 279 in all. There are at present 45 cases under treatment at Purdysburn fever hospital. At a recent meeting of the Public Health Committee of the Corporation a lengthy report on house-cleansing was considered. It appears that at present many houses only have the ashpits cleared once in every month, or even two months. It is now proposed to cleanse them fortnightly, to work the refuse destructor to its full power, and to provide two more destructors in other parts of the city. The approximate cost of daily cleansing of ashpits would be £29,000 per annum, of weekly cleansing £24,000, and of fortnightly cleansing £19,000. It is recognised that the state of the back passages, where refuse accumulates in mud, and the drainage from it soaks into the ground, is a constant source of soil contamination, and it is recommended that all back passages be flagged or concreted without delay, in such a way as to allow of thorough flushing out with a hydrant.

Dairy Cases.—The crusade against impure and adulterated milk, started by the authorities a few weeks ago, is happily being continued. Last week one dairyman was fined for leaving cans of milk uncovered in the cowshed while the shed was being cleaned. Another was fined for selling buttermilk with 68 parts of added water, in addition to the 25 per cent. allowed for churning. In a third case a milk vendor was fined for selling milk with 10 per cent. added water. The apathy of the authorities in these matters has long been a scandal in the city, and it is most satisfactory to see them stirred up at last, no doubt by the searching inquiries of the Health Commission. The Commission did not sit last week.

LETTERS TO THE EDITOR.

THE ALCOHOL MANIFESTO.

To the Editor of The Medical Press and Circular.

Sir,—Will you kindly contradict absolutely an editorial statement contained in The Medical Press and Circular, of May 8th, p. 498, under the heading, " Our Alcohol Counter-Manifesto." You there state that " the original manifesto . . . was adopted by our contemporary and signed by the various signatories under more or less misapprehension." We did not " adopt " the " manifesto." We published at their request a letter signed by a group of medical men, and we in no sense " adopted " or endorsed or supported or supplemented their views.

We are, Sir, yours truly,
The Editors.

Lancet Office, London, May 8th, 1907.

[We are glad to publish the above explanation, without which it was difficult to understand the precise position of our esteemed contemporary with regard to the original manifesto. It is to be regretted that the British public, as a whole, has insisted on regarding it as a *Lancet* manifesto, and as being in that way endorsed by the highest medical journalistic authority in the world.—Ed.M.P. and C.

THE ALCOHOL MANIFESTO.

To the Editor of The Medical Press and Circular.

Sir,—The Manifesto of the sixteen worthies in support of alcohol as a food and as medicine has somewhat staggered the temperance orators. From whence has sprung this advocacy for strong drink ? Who is responsible for this collocation of past masters of our craft ? They come from the North, from the East, and from the West. These revered teachers of twenty years ago are now canonized as saints in their exalted positions of partial retirement from active work. These advocates of the moderate use of alcohol when teaching their students at the universities, colleges, asylums, and hospitals in their daily visits to the wards had to illustrate the pernicious effects of alcohol upon their patients, and in the *post-mortem* room to show the destructive effects upon vital tissues.

As we read between the lines of the Manifesto we ask again : Who is responsible for having brought this jumble of scientific folk-lore to the Bar of public opinion to be trumpeted forth in every ale house as the verdict of self-appointed jurymen in league with " the trade " ? I am particularly surprised to see the names of certain Alienist physicians of very high reputation in our profession, who know well enough that at least 50 per cent. of the patients in their asylums are there simply because of previous indulgence in strong drink either by themselves or their ancestors. To all such and their relatives moderation is but the spark which will kindle a gigantic conflagration in many a protected home unless strong drink is for ever kept " out of bounds."

But if we turn from the cryptic utterances of these apostles of moderation to the practical experience of the physicians and surgeons on the active staff of all our general hospitals, what do we find ? Take for example the evidence of Bartholomew's Hospital during the past twenty years in the consumption of wines and spirits. In the year 1886 with 6,613 in-patients, we had 1,008 gallons of port wine consumed, 345 gallons of brandy, and 10 gallons of whisky. In the year 1905 with 6,721 in-patients, there were only 290 gallons of port wine consumed, 284 gallons of brandy and 5 gallons of whisky.

The evidence of Guy's Hospital is still more marked in the declining use of wines and spirits. In the year 1905, with 8,626 in-patients, only 99 gallons of port wine were consumed, 180 gallons of brandy and six gallons of whisky. Of this amount the resident staff no doubt help to consume a fair amount of alcoholic drinks in each hospital. As a contrast to this, other tables have been prepared to show the very rapid increase in the consumption of milk as a beverage in our general hospitals. I cannot but think that if these eminent members of our profession had anticipated the use, or shall I say the abuse, which would be made of their powerful signatures, they would never have appended their names to such a glaring attempt to bolster up a declining trade.

Side by side with this manifesto of sixteen doctors we may set the testimony of 2,000 practising doctors who are agreed "that the most perfect health is compatible with total abstinence from all intoxicating drinks."

I am, Sir, yours truly,
F. Churchill, M.D., F.R.C.S.
Cranley Gardens, London, S.W.

THE ALCOHOL COUNTER-MANIFESTO.

To the Editor of The Medical Press and Circular.

Sir,—In common, I am sure, with most of your readers, I rejoice that you have taken up an attitude of dignified protest against the *Lancet* manifesto. How much harm that ill-advised document has done can only be guessed at by those who have worked for years against the superstitution that alcohol is a necessary part of a strong man's diet. We who are "in the know" have heard about the genesis of that manifesto. It was the work of a journalist friend of the "trade," and by most of the signatures I have no doubt it was merely intended for use as an advertisement of alcoholic liquors. A temperance friend of mine informs me that the manifesto has reached him with an advertisement of certain stout which is pushed for sale under the claim that it is good for the health! Thus do the leaders of our profession lend their names—unwittingly, I hope, to forward the interests of a trade which is the wealthiest, most powerful, and most opposed to the interests of the community—a trade that lives on the weakness of human nature, and that should only be allowed to subsist in a properly-organised country under the strictest Government control and supervision. I hope your counter-manifesto (which might have gone further, in my opinion) will be able to undo some of the harm that its predecessor has done, but it will not be able to undo all, I know, and am assured.

How pitiable to see medicine—that noblest of callings — prostituted in the interests of wealthy brewers in heartless companies who aim solely at selling drink to the people.

I am, Sir, yours truly,
Salus Populi.
London, S.W.

MILK AND TUBERCULOSIS.

To the Editor of The Medical Press and Circular.

Sir,—A family doctor has not ventured to give us his views as to how the cow gets tuberculosis. If he were to study the question carefully for himself, starting free from prejudice, it might get him out of the furrow he is now ploughing with so little advantage. I will try to answer for him by a reference to the case of the human subject. Why has "consumption diminished 50 per cent. during the last quarter of a century?" It is not as the result of bacteriological investigation, but because of the improved conditions under which people live—more money, greater comfort in life, food more plentiful and of better quality, better housing, more cleanliness, &c. These are the lines on which progress is to be made and the last two especially are applicable to the case of the cow. This is my answer to his postscript.

A family doctor is on very unsafe ground when he uses the *contra mundum* argument, which can never be employed in *proof* of anything. It reminds me of the little girl and her mother. Says the child: "Is it true, mother, what everybody says?" "Yes, my dear." "Then, mother, you're a witch."

Now, I am not afraid of this argument, for the position he assigns to me is just what I was in, over a quarter of a century ago, when I was battling against the so-called Antiseptic, or Listerian, method in surgery, in which the *mundus medicus* so firmly believed at that time. I am not ashamed of the almost isolated position in which I then stood. Very much the contrary. The warning given him by the history of this subject has evidently been thrown away upon him.

I could have wished that he had stuck to the question raised by my first letter; but as he has introduced a side issue, I feel compelled to follow him in his digression, lest he should think I had no reply, and therefore it is that I proceed to point out that he is on no safer ground, when, to fortify his position on the question of enteric fever, he appeals to the result of a tolerably recent action in one of the Law Courts—the glorious uncertainties of which have become proverbial. If he have no stronger argument than this, then he is, indeed, in "very bad case." It will be a sad day for the art of medicine when medical questions at issue come to be decided in a Court of Law. In the case to which he refers, if my memory do not betray me, some of the most eminent bacteriologists supported the defence, and the verdict was based wholly on "circumstantial" evidence. The case was *not* "proved with scientific exactitude." The result of the Maidstone inquiry was the same, and I venture to affirm that no more unjust verdict was ever given than in that case.

So long as attention is centred on the water-borne theory, as it is now, so long will our ignorance of the true cause continue. I ask him to study carefully, as I have done, the history of the war in South Africa in respect of this disease, and other fevers with which it was at first confounded. It is all very well to indulge in high-flown phrases and to talk of "ten thousand instances which could be adduced in which the contagion has been clearly followed to its source." Not one of these can stand rigid investigation or furnish proof. I suppose he includes among these the King's Lynn epidemic, of which an *expert* could find no other explanation than the fact that the stream from which the water was derived, "ran past a churchyard."

As I have already indicated, I am not alone, as a family doctor seems to hold, in refusing to accept the modern teaching of bacteriology. I maintain that the bacteriologists are putting "the cart before the horse." Of this I have given conclusive evidence in my paper on bacteriology. The utter failure of the bacteriologists to produce a single typhoid bacillus from incriminated water, as in the Maidstone and King's Lynn epidemics, ought to "give them pause." As Dr. Boucher has well said: "We can make clear the exact value of the hypothesis of contagion by the microbe by means of this suggestive formula. Every time we find the epidemic we do not find the generative centre, and every time we find the generative centre we do not find the epidemic."

I am, Sir, yours truly,
George Granville Bantock.
London, May 10th, 1907.

LONDON HOSPITALS AND GENERAL PRACTITIONERS.

To the Editor of The Medical Press and Circular.

Sir,—In to-day's *Daily Telegraph*, under the heading "London Hospitals," reports are given of appeals by festival dinners for those of our London hospitals—the Middlesex, the Westminster, and St. John's Hospital for Skin Diseases. At the Middlesex dinner Lord Cheylesmore made some remarks on the general question how "hospitals should be supported and managed"; and at the Westminster Dinner Sir J. Wolfe Barry said "they were face to face with the question as to whether hospitals should go on depending upon voluntary efforts, or whether they must in the future be rate-supported, &c." Lord Cheylesmore "scouted the suggestion that the hospitals should be supported and managed by the State." I think that some of us would not agree with Sir J. Wolfe Barry that "the patients would lose the highest skill in the medical and surgical world," if our hospital system were to change from the old-fashioned kind of charity on which they have long depended for a State supported system; for it cannot be said that our London hospitals are the very best schools of medicine and surgery. There is little to encourage good teaching by the physicians and surgeons at our hospitals, who not unnaturally look more to income derivable from private and consulting practise, that come from reputation, than from teaching. It would be well if the great body of general practitioners were to express their opinion on this question of our hospitals.

I am, Sir, yours truly,
R. L.

May 10th, 1907.

TINKERING WITH THE LAW.

To the Editor of The Medical Press and Circular.

Sir,—Assuming that Lord Hylton's Bill becomes law—a very doubtful assumption—it will do nothing to interfere with the main power of quackery, or to diminish the gigantic evils to which fraudulent practice is giving rise. Not five per cent. of quacks are using the Companies Act as a cloak. They do not need it; many other more safe and convenient devices are available. The favourite method now is to use the name of a bogus doctor, to pretend to sell nostrums or apparatus of his invention, and by cunningly-worded advertisements to lead the public to believe that in consulting the quack they are dealing with a legally qualified medical man. To illustrate this I enclose two advertisements from the same recent issue of the *Times*—the leading journal, which, up to late years, was the friend of the profession and the denouncer of quackery—and two from country papers—samples from hundreds of a similar kind appearing daily in the London and Provincial Press. A separate law to prevent unqualified solicitors from practising under the cover of the Companies Act is not needed. It is impossible for a fraudulent lawyer to employ with impunity in advertisements or circulars words remotely implying that he is qualified. The Statute is clear, magistrates never fail to administer it with severity, and the continued existence of unqualified solicitors in any guise is impossible. A similar Act could be constructed to meet the case of the doctors, whilst very slight amendment of existing laws would ensure the prosecution of the majority of vendors of nostrums, panaceas, and bogus medical apparatus for obtaining money under false pretences. In the meantime quackery flourishes apace. It affords large incomes to many clever adventurers. The latest stamp duty returns show that no less a sum than £2,764,557 was spent in quack medicines in one year. At least £1,500,000 is annually expended in quack advertisements; and this has sufficed to subourne the entire newspaper press, from high to low, with rare exceptions, in tacit support of this the most cruel of all systems of cynical knavery. The silence of the great bulk of the newspaper press being thus assured, there remains only one means by which the exposure of quackery can be effectively brought about, namely, a Royal Commission. The story which could be there unfolded would compel speedy legislation of a drastic character. If Lord Hylton and those acting with him desire this consummation, it would be well if, instead of tinkering with the present law they would devote their energies towards achievement of the necessary preliminary step I advocate.

I am, Sir, yours truly,
Henry Sewill.

Cavendish Square, May 10th, 1907.

According to the *Diario Universal*, the organ of the Conde de Romanones, the epidemic which is raging at Cartagena is not typhus, but bubonic plague. Three hundred cases are said to be in hospital, and 2,000 tubes of serum have been requested by the Governor.

A case of cerebro-spinal meningitis has occurred at Derby, the victim being a little child, who has succumbed to the disease. It had no connection with a similar case that occurred at Derby about six weeks ago.

OBITUARY.

SAMUEL LODGE, M.R.C.S. Eng., L.R.C.P. Ed.

A Notable Career.

We regret to announce the death of Dr. Samuel Lodge, which took place on May 9th, at Bradford, after a prolonged illness, at the age of 83 years. In the later years of his life, Dr. Lodge had been stricken down with serious illness upon more than one occasion, but he displayed considerable recuperative power, and after a short absence he was back in harness. Born at Witney, near O ford, on March 16th, 1824, Dr. Lodge was the eldest of the large family of a yeoman in passable circumstances. An apt scholar, he attracted the attention of the headmaster of Witney Bluecoat School, from whom he received private tuition. Even in these early days he had made up his mind to be a doctor, and prosecuted his studies to this end. He became the articled pupil of the late Dr. Field, a medical man of considerable standing in the Dudley Hill district. During his apprenticeship he was accustomed to walk to Leeds to hear the medical lectures, which at that time were delivered in the Infirmary, and to discharge the duties of dresser in that institution. It is an interesting fact that he acted as dresser at the Leeds Infirmary for Dr. Thomas Pridgin Teale (father of the present surgeon of the same name), a distinguished member of the faculty, who introduced what is known as amputation by the square flat. Not until 1859 did Dr. Lodge qualify as an M.R.C.S. of England and L.R.C.P. of Edinburgh. Dr. Lodge started practising on his own account at Bradford, and his first public appointment was that of medical officer of the third district of the Bradford Poor Law Union, a position which he held for thirty-five years, and resigned so recently as 1903. The offices of police surgeon to the City and the Bradford West Riding police forces were obtained later, and were retained to the last by Dr. Lodge.

Very early in his medical career Dr. Lodge had the serious misfortune to meet with an accident which resulted in the destruction of one of his eyes. Later in life the accident befell which caused his lameness. In visiting his patients he was wont to ride on horseback a good deal, and it was a fall from his horse that caused him to be laid up for many months with a broken thigh. More recent was the attack made upon Dr. Lodge by a prisoner at the Town Hall. Passing through a corridor where the prisoners were allowed to parade the police surgeon suddenly felt a burning pain in the neck, and turning round discovered that he had been stabbed. His assailant proved to be a lunatic who had managed to conceal a pen-knife about him. Fortunately the wound was not of a dangerous character.

Dr. Lodge's long career formed a link between the old surgery and the new. He particularly distinguished himself as one of the body of medical men who first took up the study of wool-sorter's disease, and established its identity with splenic disease in cattle. As early as 1854, he published a booklet on woolsorters' disease. All his life he was a wonderful worker, and it is estimated that of autopsies alone he must have made upwards of a thousand in Bradford.

Dr. Lodge was something of a virtuoso. A busy life did not prevent his indulging in the hobby of collecting art treasures and his house was adorned with many excellent pictures and interesting pieces of antique furniture.

T. B. LUSCOMBE, M.R.C.S, L.R.C.P., L.S.A.

The death took place at Teddington on April 29, of Dr. T. B. Luscombe, a gentleman well known to many Twickenham residents. The deceased, who was 54 years of age, succumbed to a severe attack of influenza after only a fortnight's illness.

Dr. Luscombe was a member of the Royal College of Surgeons, a Licentiate of the Royal College of Physicians, and a Licentiate of the Society of Apothecaries. Coming to Teddington about 25 years ago he founded a practice as a surgeon, and pursued his profession here with considerable success. He was a life-long abstainer, and on many occasions publicly advocated the cause of total abstinence. He was of a quiet and unassuming disposition, and was highly respected throughout the neighbourhood. Never very robust, he unfortunately met with a serious accident some two years ago, when he was thrown from his dog-cart, and sustained severe concussion of the brain. Although he recovered, and was able to resume his professional duties, the shock told seriously upon a none too robust constitution, and he was never quite the same in health. He was on the medical staff of the Cottage Hospital for many years.

His chief hobby, whenever he could find relaxation from his arduous professional labours, was the breeding of pedigree Jersey cows on the twelve acres of land attached to his residence, Cromer House, Hampton Road. He could also be counted upon to support any worthy cause for the advancement of the social and spiritual condition of the working classes, and his loss will be keenly felt.

JOHN T. O'HARE, M.B., Ch.B., B.A.O., D.P.H

WE regret to announce that Dr. John J. O'Hare died at his residence, Hill Street, Newry, May 3rd. The deceased was 29 years of age, and had only taken his degrees five years ago. Before leaving Dublin to start practice in his native town of Newry, Dr. O'Hare filled the position of Assistant Master in Holles Street Hospital for three years, and previous to that appointment he was resident surgeon to the Mater Hospital. During his entire medical career his genial manner and kindly disposition endeared him to all with whom he came into contact. Dr. O'Hare had been ailing for only a fortnight.

R. JALLAND, M.R.C.S., L.R.C.P.

THE death occurred on May 9th, of Dr. Robert Jalland, a retired medical practitioner, of Horncastle, at the age of 77. Deceased, who was a native of Rolleston, Notts, came to Horncastle early in life as assistant to the late Dr. J. B. Boulton, afterwards practising on his own account. The late Dr. Jalland was for many years a Governor of the Horncastle Grammar School, and some years ago published a comprehensive history of that ancient institution. One of the sons is Mr. G. H. Jalland, a well-known contributor to *Punch*; the other was for some time connected with Mr. Benson's Company as manager.

PROFESSOR POIRIER, PARIS.

☛ ONE of the most celebrated French surgeons, Prof. Poirier, died on May 1st, in Paris. He returned recently from Trouville, where he and his family had been stopping. His condition being very unsatisfactory, he consulted Professors Chauffard and Cunéo. His death which was quite unexpected, will cause a great sensation in medical and society circles.

Professor Poirier was a Norman by birth. He succeeded Professor Farabœuf in the chair of anatomy at the Faculty of Medicine about six years ago. His lectures from the first attracted large numbers of students. He was celebrated not only for his skill in diagnosing and operating, but for his cheery optimism and humour, which proved of great service to many patients. On M. Waldeck-Rousseau, who was one of his most intimate friends, he performed the operation which was much commented on recently. Professor Poirier recently formed a cancer research league. He was barely fifty years of age.

GEORGE BECK, a German waiter, was ordered six months' hard labour for threatening the life of David Hunter, a medical superintendent of Goodmayes Asylum, Essex. Prisoner had an idea that his wife was being ill-treated in the asylum. He now apologized for his conduct towards the doctor.

SPECIAL ARTICLES.

THE PREHISTORIC INHABITANTS OF ENGLAND.

AT the Royal College of Surgeons on Friday last, Professor William Wright, F.R.C.S., concluded a series of three lectures on the "Prehistoric and Early Historic Inhabitants of England." The following is an extract of the lectures which were largely attended :—

After a brief reference to the methods of investigation and the division of Time. Prof. Wright mentioned the presence of anthropoid apes on the Continent in the Meiocene Age. The evidence for Pliocene man was much stronger without being quite conclusive. In England his presence is attested by the high plateau flints of Kent, by flints found at Dawlish, and in the Cromer forest bed.

On the Continent there were three early and different types of Pleistocene man as exemplified by the Spy, Grimaldi, and Brunn Skeletons. In England the discovery of the Galley Hill skeleton in undisturbed stratified palæolithic gravel with a Pleistocene fauna and the unearthing of a fragment of a calvaria near Bury St. Edmunds in high palæolithic gravel between the valleys of the Lark and the Linnet, testify to his presence and appearance. His habits were his dwelling in caves and rock shelters, his practise of painting the body, and adorning himself with shells, crystals, and teeth. He had knowledge of fire and light, and interred, in some cases at least, the dead. He was astonishingly versatile as an artist, being equally proficient in sculpture, engraving and painting. The average height of palæolithic man was five feet five inches.

Professor Wright defined the neolithic age as that characterised by the culture of the earliest Swiss lake dwellings—the polishing of weapons, the practice of agriculture, the presence of domestic animals, and the knowledge of weaving. The period between that which saw the departure of the Reindeer from Southern Europe and this neolithic age he designated the Mesolithic Age. On the Continent this was characterised by harpoons made from deer-horn, coloured pebbles —possibly the first attempt at writing—and the kitchen-middens of Denmark and Portugal. In Britain evidence for the corresponding age is found in such caves as those of Obor and Aronsay, in the kitchen-middens of Hastings and Sevenoaks, and in the rude flints from Grimes Graves and Cissbury.

Neolithic man is in all probability to be identified to-day with the short dark, dolichocephalic inhabitants of Cornwall, Devon, Wales and Ireland. His language was probably Gaelic.

Towards the end of the neolithic period or the beginning of the bronze, a new type appeared, along the Eastern shores of our country. This type was in strongest possible contrast to the earlier type and there could be little if any doubt that it came from the region of the Baltic. Skulls with the closest resemblance to the famous Borreby skull from Denmark have been obtained from the round burrows of East Yorkshire. The lecturer showed how archæology strongly supported the anthropological evidence for this hypothesis. The lecturer briefly referred to the ethnology of Europe at the dawn of history and produced evidence for the downward movement of a tall fair-haired people upon the short, dark-haired people of the Mediterranean. He referred to the very mixed character of Europe ethnologically as gathered from the Homeric poems and the earliest historical records.

The evidence of Cæsar as to the inhabitants of England was considered, particularly his statement that the eastern portion of England was inhabited by tribes of Belgæ who had passed over. taking the names of the corresponding Continental tribes with them, into England from Gallia Belgica. They spoke the Brythonic language. A short account was given of the life, and physical appearance of the inhabitants of England during the early Iron Age, as obtained from the examination of such sites as the Danes Graves, Yorkshire, the urn fields, at Aylesford, the lake dwelling at Glastonbury and the cist graves of Harlyn Bay. In conclusion the lecturer gave an account of the coming of the Romans, and expressed the view that their ethnological effect was more pronounced and permanent than is usually considered to be the case.

REVIEWS OF BOOKS.

THE MENSTRUAL FUNCTION IN SKIN DISEASES. (*a*)

IN the study and treatment of skin diseases it has long been recognised that for success the patient as well as the disease must be studied and treated. We believe that every teacher and every text-book of value insists on the necessity of general as well as local treatment in dealing with skin diseases. If it be true, as Jacobi asserts, that 46 per cent. of women suffer more or less during menstruation, it is not surprising that one can show that women who are the subject of skin diseases experience more or less increase in their symptoms at this period. Our author has brought together a list of some twenty-two skin diseases in which he has found aggravation of the symptoms during menstruation and with him we believe the list might be much enlarged. The exact explanation of the connection between the skin lesion which is aggravated and the menstrual epoch is a much more difficult matter than the general establishment of the connection between them, and we fear the book before us has not added much to our knowledge on this point. The influence of menstruation in aggravating acne, and, indeed, all skin lesions due to infection by micro-organisms has long been recognised, and recently our knowledge of this connection has been extended by the demonstration of the fact that at this period the opsonic index of the blood for many micro-organisms is considerably lowered. Dr. Bulkley, however, does not give us any information on this point. The book, we believe, will be useful in so far as it impresses on the practitioner the necessity of general as well as local therapeutics in the treatment of skin diseases. Appended to the book is a very full bibliography on the subject which will be of service to those who wish to pursue the subject further.

FORCHHEIMER ON INTERNAL DISEASES. (*b*)

THIS book, which is intended for the advanced student and practitioner embodies the results of Dr. Forchheimer's thirty years' experience in hospital and private practice, and as such is a welcome addition to any medical library. Every practitioner will recognise the value of a book which enables him to revise his therapeutic methods by comparison of them with the ripe and reasoned experience of a successful teacher and practitioner. In many points no doubt our readers, like ourselves, will differ from the opinions expressed by Dr. Forchheimer, but, on the whole, we believe the teaching contained in the book will be admitted to be sound and in many cases admirable. The book contains a useful appendix on the composition of food materials as estimated by Atwater for the United States Department of Agriculture.

A TREATISE ON SURGERY. (*c*)

IN presenting a new work on surgery, the author has endeavoured to bring together the most recent and improved methods of surgical practice, and, with the aid of cross-references, to arrange these in a form readily available to the student and practitioner. The first volume deals with general surgery. An excellent and most useful chapter is given on "Laboratory Aids in Surgical Diagnosis and Prognosis." The chapter on Bandaging is one of the best with which we are acquainted in any surgical work and is illustrated with photographs which, in the way they fulfil their purpose, are excellent.

The second volume deals with regional surgery. We have perused both volumes of the work with much pleasure. It is necessarily more or less a compilation, but it is pleasant to read, well illustrated, thoroughly up-to-date, and abounds with the names of authorities on every subject dealt with. There is a full index and a separate index of names.

The book is one we can recommend to the student and practitioner. Few, if any, could read it without pleasure and profit. We have, however, one suggestion to make—this work errs, as do most books of American origin, on the score of weight (the two volumes weigh nearly 14 pounds). The class of paper on which the book is printed no doubt improves the character of the illustrations somewhat, but the weight of the book to the student at any rate will cause considerable inconvenience, and we fail to see the reason for this artificial creation of weight at the expense of comfort to the reader.

THE EXAMINATION OF THE CHEST. (*a*)

MANY manuals have been written on "the how and the why" of examining the thorax and its contents, but Dr. Gee's concise and precise little work still maintains its popularity as is evidenced by the appearance of a fifth edition. It is not only the work of an experienced physician, but is also the outcome of a long and useful professional career among students. The author is a lover of aphorisms, and is a marker in the dogmatic expression of clinical facts and has, moreover, a keen insight into the needs and necessities of the student desirous of equipping himself for the arduous duties of practice. This work has long been a favourite with Bart's men, but its merits have gained for it a field among all English students. In the present edition its familiar form is maintained and, strange to say, it has not been increased in bulk. While it has many advantages, it is not without its limitations. It is perhaps a pity that the author has considered it wisest to omit all reference to the use of X-rays in the diagnosis of diseases of the chest. The usefulness of the book would have been increased by a more liberal use of illustrations. We think, moreover, that a convenient system of "short-hand" charting of pulmonary and cardiac signs might have been suggested to the student, for some such is almost essential in actual practice. But, as far as the work goes, it is a model of systematic arrangement, clear definition, and accurate writing.

THE MEDICO-LEGAL SOCIETY. (*b*)

AMONG the recently formed societies specially appealing to the medical mind, but also concerned with matters outside the strictly professional pale, the Medico-Legal Society occupies a foremost place. Although only a six-year-old, it has already accomplished much, and in this, its third volume of Transactions, affords abundant evidence of vigorous development. It contains valuable articles on finger-print evidence, consultations among medical witnesses previous to trials, inconclusive post-mortem examinations, alcoholism, and irresponsibility, insanity and murder, and the modes of ascertaining the fact and cause of death. There is much in this volume which demands the careful study of all serious students of forensic medicine. Although the Medico-Legal Society has a roll of only 104 members, it is evidently destined to fulfil a most useful and necessary function, and such a volume as this will extend the sphere of its service far beyond the limits of its strict membership.

(*a*) "The Influence of the Menstrual Function on Certain Diseases of the Skin." By L. Duncan Bulkley, M.D., Physician to the New York Skin and Cancer Hospital. 8vo, pp. vii. and 108. London: Rebman, Limited. 1906.

(*b*) "The Prophylaxis and Treatment of Internal Diseases." By F. Forchheimer, M.D., Professor of Theory and Practice of Medicine and Clinical Medicine, Medical College of Ohio. 8vo, pp. xvii. and 652. Sidney Appleton and Co. 1906.

(*b*) "Transactions of the Medico-Legal Society for the Year 1905-1906." Edited by R. Henslowe Wellington. Lecturer on Medical Jurisprudence, Westminster Hospital School of Medicine; and Stanley B. Atkinson, M.A., M.B., J.P. Vol. III., pp. 122. London: Bailliere, Tindall and Cox. 1906. Price 7s. 6d.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for The Medical Press and Circular.

RECENT PATHOLOGICAL LITERATURE.

Recent Contributions on Opsonics.—Though the subject is not at present receiving the wide-spread attention which was given to it a year ago, yet our knowledge of opsonics and their various relations is growing by constant contributions. Among the more recent papers of importance are two abstracts here:—

I.—Value of the Opsonic Index in the Diagnosis of Tuberculosis.—Stewart and Ritchie (*Edinburgh Medical Journal*, May, 1907) discuss this subject after the examination of the blood in 122 cases. Their cases fell into two groups—82 probably tuberculous, and 40 probably non-tuberculous. Of the 82 tuberculous cases exactly one-half had an index within normal limits; of the 40 non-tuberculous 29 had an index within normal limits, and the remainder an index outside those limits. A diagnosis based merely on one examination would therefore have led to serious errors. Seventy-five patients were treated however, by injections of small quantities of tuberculin, and their bloods examined on the succeeding days. Sixty-two of these were tuberculous, and in 56 a definite negative phase followed the injection; in none of 13 non-tuberculous patients did any negative phase occur. The authors conclude:—(1) a single estimation of the opsonic index is an unsatisfactory method of diagnosis, as both tuberculous and non-tuberculous cases fall within and without normal limits. (2) If a negative phase appear after inoculation, the presence of tuberculosis may be diagnosed. (3) The absence of a negative phase indicates the absence of a tuberculous infection. The authors add that they have reason to believe that a patient recovered from tuberculous disease, like any patient without the disease, fails to show a negative phase.

II.—Marmorck's Serum and the Opsonic Index.—Bosanquet and French (*British Medical Journal*, April 13th, 1907) publish the report of an investigation into the effect of Marmorck's anti-tuberculous serum on the opsonic index of the patient treated. Particulars, with opsonic charts, are given of five cases of advanced tubercle of the lung. The result was very similar in all cases. Rectal injections given daily were accompanied by a high opsonic level, which, however, did not persist after the injections were discontinued. On the other hand, subcutaneous injections in the one case where they were given produced a rapid fall of the opsonic index, which subsequently rose when the rectal method was substituted. That the raising of the index was not due to the serum being itself rich in opsonics is shown by the fact that when tested the serum was found to have an index of only .127. The general result is in support of the good opinions expressed by many clinical observers of the curative effect of Marmorck's serum. R.

Immunity toward Cancer.—Clowes (*Cleveland Medical Journal*, February, 1907) summarises the evidence which has led him to believe that mice may develop an immunity toward carcinoma. (1) Spontaneous recovery from three tumours occurs. (2) After such spontaneous recovery mice are not reinoculable. (3) A small percentage of tumours is obtained on reinoculation of mice which have failed to take on the first inoculation of tumour material. (4) Inoculation with one strain of tumour gives a certain protection against future inoculation with another strain. (5) The serum of mice which have spontaneously recovered appears to exert a slight effect upon growing tumours when injected directly and also to interfere to a certain extent with the development of tumour cells when admixed with the latter previous to inoculation. All the evidence accumulated by Clowes tallies with the parasitic theory, though it is not incompatible with Ebreich's suggestion that cancer cells tend to proliferate by virtue of their possessing side chains with greater affinity for food than those of the normal cells of the body. R.

Absorption from the Peritoneal Cavity.—Buxton and Torrey publish a series of papers (*Journal of Medical Research*, 1906, 1907) bearing on the absorption of bacteria and toxins from the peritoneal cavity. Their experiments have a direct relation to the pathology of peritonitis. They find:—(1) Bacteria injected into the peritoneal cavity of animals even in minute doses reach the circulation in a few minutes; (2) this rapid absorption takes place by the lymphatics of the diaphragm; (3) in cases of peritonitis in man, in order to avoid the rushing of bacteria to the diaphragm, the half-sitting posture is indicated, and flushing of the peritoneal cavity is contra-indicated. The authors make the proviso that their investigations have no bearing on streptococcal infections, which probably cause death by rapid systemic action. On the other hand, colon and similar infections tend to become localised, and treatment should be directed toward assisting this tendency. Irrigation of the peritoneal cavity may clear out some of the invading organisms, but it must at the same time wash out the protective bodies, and it may spread the invading organisms over a larger area of peritoneum. The authors quote from Harte and Ashurst (*Annals of Surgery*, 1904, 43) a table showing the different rates of mortality after operation for typhoid perforation, different methods of dealing with the peritoneum having been adopted. With drainage, without wiping or irrigation, there was a mortality rate of 41 per cent., with wiping and drainage 61 per cent., with irrigation and drainage 74 per cent., and with wiping, irrigation, and drainage 90 per cent. These figures must, of course, be discounted to some extent, since it is probable that the more rigorous measures were adopted in the more severe cases, but they at least suggest that the mildest treatment is the best. R.

The Diagnosis of Cholera.—Armand Ruffer and his colleagues publish (*British Medical Journal*, March 30th, 1907) some important results of their investigations on the bacteriological diagnosis of cholera. Up to the present the agglutination test has been regarded as perhaps the most trustworthy in the bacteriological diagnosis of any organism, and reliance has sometimes been placed on it without due precautions being taken. Ruffer shows that in cholera patients and in others there may be an infection of a vibrio resembling in many particulars the cholera vibrio, and consequently that there may be developed in a cholera patient agglutinins specific to these pseudo-cholera vibrios. In pursuit of this view Ruffer discovered in drinking-water obtained from ships, six strains of vibrio agglutinated in high dilutions by serum from a cholera patient. That they differed from the true vibrio was shown both by their failure to produce disease in the ships where they were found, and by their possession of multiple cilia. His conclusions are:—(1) A certain number of vibrios, although agglutinating to some extent with cholera serum, are sharply differentiated morphologically from the cholero vibrio, by the fact that they are multiciliated; (2) whereas some vibrios found in ship water are agglutinated by very dilute secretions of cholera serum, others are agglutinated by far stronger solutions only. The latter form a transition stage, so to speak, between the non-agglutinating and the highly agglutinating vibrios; (3) although an active cholera serum agglutinates all the vibrios to some extent, yet only two of these vibrios when injected into animals produce serums having a powerful agglutinating effect on cholera vibrios; it is concluded, therefore, (4) that it is not advisable to trust to the agglutination test only in the bacteriological diagnosis of cholera. The test is useful, but not specific. R.

Diagnosis of Sleeping Sickness.—MARTIN (*Annales de l' Institut Pasteur*, March, 1907) publishes a careful description of five cases of sleeping sickness, treated at the Pasteur Hospital. The clinical diagnosis rarely presents any difficulty, but there are certain points which may give assistance in doubtful cases—(1) *Enlargement of the Glands.* In all Martin's cases the glands of the groin and the axilla were enlarged; other observers emphasise enlargement of the glands of the neck as a characteristic feature. (2) *Presence of the tympanosome in the blood.* In all cases the trypanosome is in the blood from the start of the disease. It can usually be found by simple examination of a drop of blood beyond slide and cover glass. In other cases it may be necessary to centrifuge the blood with citrated water, and search the layer of white corpuscles which lies at the top of the deposit. In rare cases it is necessary to inoculate animals with the blood. For this purpose, guinea-pigs, rats, mice, or monkeys may be employed. (3) *Auto-agglutination of the blood.* The blood of subjects infected with trypanosomiasis presents a curious feature when allowed to stand between a slide and cover glass: the corpuscles rapidly come together into heaps of various sizes, visible to the naked eye, the intervening serum becoming clear. (4) *Puncture of the lymph glands gives a* fluid containing many trypanosomes. (5) Presence of trypanosomes in the special fluid is a constant feature. The fluid should be centrifugalised before examination. R.

Cardiac Anomaly.—Ingalls reports a rare cardiac malformation (*Johns Hopkins Hospital Bulletin*, April, 1907). The specimen was obtained from a patient who died in hospital, but who had not suffered from cardiac trouble during life. The heart at the autopsy was slightly larger than normal, but nothing noteworthy was detected till the pulmonary veins were examined. These were five in number, two on the left and three on the right side. Of these, two, namely, the upper two right veins, opened abnormally into the superior vena cava, while the remainder opened normally into the left auricle. The walls of the left auricle were normal everywhere except at the extreme upper part, where the septum was deficient, and thereby a communication was established between the cavity of the left auricle and the superior vena cava. The abnormality appears to be almost if not quite unique, as no similar cases could be found reported in the literature. M.

Acute Pancreatitis.—Egdahl has analysed the records of 105 cases of acute pancreatitis (*Johns Hopkins Hospital Bulletin*, April, 1907), with the special object of determining the more important etiological factors which produce that disease, and, in addition, reports two cases of his own. The conclusions at which he arrives are as follows:—(1) Gallstones are probably the most common single cause of pancreatitis, having been present in 42 per cent. of the present series. (2) Gastro-intestinal disorders are the next most common cause of acute pancreatitis; retrojection of bile probably being caused by intestinal disorders closing the papilla of Vater. In the present series there was alimentary disturbance in 38 per cent., and a history of alcoholism in 17 per cent. (3) Other causes of pancreatitis appear to be typhoid fever, tuberculosis, trauma, syphilis, emboli, appendicitis, malaria and gastric ulcer. (4) The most common organism present is the B. coli communis; while next in frequency come the streptococci and the staphylococci. (5) Typhoid fever is the most common of the acute febrile diseases present, according to the previous histories of these cases of acute pancreatitis. M.

Necrosis of Maxillary Bones after Measles.—Dr. Majima calls attention to necrosis of the superior maxillary bones as a sequela of measles (*Sei-I-Kwai Medical Journal*, February 28th, 1907). He points out the fact that the condition is barely noticed in the text-books, although the allied condition, gangrenous stomatitis, has been for so long recognized. He himself has met with two cases within the course of a month. The first was that of a boy, æt. 6½, who, following measles, suffered from complete necrosis of the front part of the alveolar process of the upper jaw. The second case was that of a boy, æt. 2. Ten days after the onset of measles the incisor teeth of the upper jaw fell out, and the alveolar process was found in a necrotic state, and later had to be removed. The cause of the necrosis is still unknown, but the writer believes that its direct connection with measles is easily demonstrated, and in proof of his point has collected some of the scanty references in the literature. M.

Tuberculous Osteitis Simulating Sarcoma.—Gaudier and Bernard (*La Rev. Internat. de la Tuberculose*, April, 1907, p. 287) report a case of the above condition occurring in the lower jaw of a child, æt. 5. The patient was brought to hospital with a swelling of the entire left half of the mandible, and no history of previous dental trouble could be obtained. The swelling had developed slowly, and did not fluctuate, but was quite hard and painless, presenting, in fact, the typical appearance of a sarcoma of this region. The tumour continued to grow slowly for some time, and then at last the skin, which at the beginning was quite normal, became involved, and several fistulous openings formed. Through these necrotic tubercular material and bony fragments were discharged, and a good result, except for the existence of some deformity, was ultimately obtained. The authors insist on the rarity of this form of osteitis of the mandible. M.

The Blood in Asthma.—Several investigations of the blood and sputum in cases of neurotic asthma have been made and have established the existence of eosinophil. Saleckei (*Munch. Med. Woch.*, 1907, No. 8) has now made an extensive investigation of the blood in fourteen cases, both during and between attacks, and reports his results. During the intervals there exists a distinct eosinophil, while the percentage number of neutrophile cells is lessened, and the number of mononuclear cells is increased. Shortly after an attack, on the other hand, the total number of leucocytes is increased, and the neutrophiles now preponderate, while the eosinophiles are decreased possibly owing to the outpouring of eosinophiles in the sputum. The mononuclear cells, grouping under this term both lymphocytes and hyaline cells, do not undergo much change in number after attacks. M.

North-East London Post-Graduate College Conversazione.

A SUCCESSFUL conversazione of the North-East London Post-Graduate College (Prince of Wales's General Hospital) was held on May 7th. The guests, including ladies, were received by Mr. and Mrs. John Langton, and much interest was displayed by them and the members of the nursing staff, who were also invited, in the various medical and surgical exhibits, and the special X-ray demonstrations given at intervals throughout the evening by Dr. Pirie, the hospital radiographer. A conjuring entertainment by Mr. Algernon Fox was also much appreciated. The opportunity was taken by a large number of those present to inspect the new wards and theatre of the hospital, which had been formally opened in the afternoon by T.R.H. the Prince and Princess of Wales, accompanied by the Princess Louise (Duchess of Argyll), the President of the Hospital.

MEDICAL NEWS IN BRIEF.

Royal College of Surgeons, England.

AT a meeting of the Council. held on Thursday last, Mr. Henry Morris, F.R.C.S., president, in the chair. Dr. Alex. Hill, Master of Downing College, Cambridge, and Professor Arthur Thomson, of the University Museum, Oxford, were admitted Fellows of the College. The Jacksonian Prize for the year 1906 was presented to Mr. Donald Armour, Assistant-Surgeon to the West London Hospital. This being the first occasion that the prize has been won by a Canadian. The President reported that Dr. Thomas James Walker, of Peterborough, to mark the completion of the fiftieth year of his membership of the College, had presented to the college a volume of original notes of John Hunter's lectures. It was resolved that the best thanks of the Council be given to Dr. Walker for his valuable gift.

Alterations in the Midwifery Regulations.—A report was received from the committee of the conjoint examining board recommending the following alterations with regard to the course of instruction in midwifery for candidates for the diplomas of the two Royal Colleges:—1. That every student shall himself conduct twenty labours. 2. That before conducting such twenty labours he be required (*a*) to have held the office of Medical Clinical Clerk and of Surgical Dresser at a recognised hospital during six months each; and (*b*) to have attended a course of practical instruction in Midwifery. 3. That the certificate of having conducted the required number of cases be signed by a member of the staff of a Lying-in-Hospital or of the Maternity Charity of a General Hospital, or by the Dean of the Medical School attached to the General Hospital. 4. That every student be required to discharge the duties of Clinical Clerk in the Gynæcological Wards or Out-Patient department of a recognised hospital. 5. That every student be required to complete the curriculum of professional study before presenting himself for examination in Midwifery and Gynæcology. The recommendations were adopted.
